The ALT Special Use Top Level Domain  
draft-wkumari-dnsop-alt-tld-02

## Abstract

This document reserves a string (ALT) to be used as a TLD label in non-DNS contexts. It also provides advice / guidance to developers developing alternate namespaces.

## Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 5, 2015.

[1.](#) Introduction

Many protocols and systems need to name entities. Names that look like DNS names (a series of labels separated with dots) have become common, even in systems that are not part of the DNS.

This document reserves the string "ALT" (short for "Alternate") as a Special Use Domain ([\[RFC6761\]](#)) that should be used in the right-most label position to signify that this name is not rooted in the DNS, and that normal registration and lookup rules do not apply.

[1.1.](#) Requirements notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [\[RFC2119\]](#).

[1.2.](#) Terminology

This document assumes familiarity with DNS terms and concepts. Please see [\[RFC1034\]](#) for background and concepts.

- o DNS context: The namespace administered by ICANN. This is the namespace / context that "normal" DNS uses.
- o non-DNS context: Any other / alternate namespace.

Internet-Draft

Reserve ALT TLD

July 2014

## [2.](#) Background

The DNS is a tree, and so has a single root. Conventionally, a name immediately beneath the root is called a "Top Level Domain" or "TLD". TLDs usually delegate portions of their namespace to others, who may then delegate further. The hierarchical, distributed and caching nature of the DNS has made it the primary resolution system on the Internet.

The success of the DNS makes it a natural starting point for systems that need to name entities in a non-DNS context. These name resolutions occur in a namespace distinct from the DNS. A number of good examples of these sorts of systems are documented in Special-Use Domain Names of Peer-to-Peer Systems [[I-D.grothoff-iesg-special-use-p2p-names](#)].

In many cases, these systems build a DNS style tree parallel to the global DNS administered by IANA. They often use a pseudo-TLD to cause resolution in this alternate namespace, using browser plugins, shims in the name resolution process, or simply applications that only use this alternate namespace.

In many cases the creators of these alternate namespaces have simply chosen a convenient / descriptive string and started using this. These new strings are "alternate" strings, and not actually registered anywhere or part of the DNS. However they appear to be TLDs, as they are in the right-most position of a name. Issues may arise if they are looked up in the DNS. These include:

- o User confusion: If someone emails a link of the form foo.bar.pseudo-TLD to someone who does not have the necessary software to resolve names in the pseudo-TLD namespace, they may become confused.
- o Excess traffic hitting the DNS root. Lookups may leak out of the pseudo-TLD namespace and end up hitting the DNS root nameservers.

- o Collisions: If the pseudo-TLD is eventually delegated from the root zone the behavior may be non-deterministic.
- o Lack of success for the user's original goal.

A significant number of these alternate name resolution systems are specifically designed to provide confidentiality of the looked up name, and provide a distributed and censorship resistant namespace. For example, the Tor project use of .onion is intended to provide a confidential and alternate name resolution process. This goal may be

defeated if the queries leak into the DNS, for example if a Tor user shares a link with a friend who isn't using the Tor browser.

### [3.](#) The ALT namespace

In order to avoid the above issues we reserve the .ALT label. This label should be used as a pseudo-TLD (in the right most (TLD) position of a name) to signify that this is an alternate (non-DNS) namespace.

Alternate namespaces should differentiate themselves from other alternate namespaces by choosing a name and using it in the label position just before the pseudo-TLD. For example, a group wishing create a namespace for Friends Of Olaf they may choose the string "foo" and use any set of labels under foo.alt.

As they are in an alternate namespace they have no significance in the regular DNS context and so should not be looked up in the DNS context. Unfortunately simply saying that "something should not happen" doesn't actually stop it from happening, so we need some rules to deal with these.

1. Stub resolvers MAY elect not to send queries to any upstream resolver for names in the ALT TLD.
2. Iterative resolvers SHOULD follow the advice in [\[RFC6303\]](#), [Section 3](#).
3. The root zone nameservers should either return NXDOMAIN

responses, or the ALT TLD should be delegated to "new style" AS112 nameservers.

Groups wishing to create alternate namespaces SHOULD create their alternate namespace "under" a label that names their namespace, and "under" the ALT label. They SHOULD choose a label that they expect to be unique / descriptive. As there is no registry for the ALT namespace uniqueness is not guaranteed.

Currently deployed projects and protocols that are using pseudo-TLDs (for example, the ".onion" pseudo-TLD (and other labels in [\[I-D.grothoff-iesg-special-use-p2p-names\]](#)) are not expected to move under the ALT TLD (but may do so if they wish; this is a common resource). Rather, the ALT TLD is being reserved so that future projects of a similar nature have a designated place to create alternate resolution namespaces that will not conflict with the regular DNS context.

A number of names other than .ALT were considered and discarded. In order for this technique to be effective the names need to continue to followed the DNS format (a prime consideration for alternate name formats be that they can be entered in places that normally take DNS context names), this rules out using suffixes that are not themselves DNS labels. Another proposal was that the ALT TLD instead be a reservation under .arpa. This was considered, but rejected because of we are suggesting that this be served as an [\[RFC6303\]](#) and that recursive operators configure themselves to serve empty authoritative zones for the reserved labeled. There is a concern that if there were placed under .arpa less experienced nameserver operators may inadvertently cover .arpa. A more significant concern is that the scope of the issue if the query does leak, and the fact that this would then make the root of the alternate naming namespace a third level domain, and not a second one. A project may be willing to have a name of the form example.alt, but example.alt.arpa may be not look as good [TODO: Better wording here. Don't want to say "vanity" ! ]

#### [4.](#) Advice to developers

An option would be for name resolution systems that operate outside to DNS to "root" themselves under a DNS name that the project or

organization controls. So, for example if the Tor project controls `tor.example.com` it could "root" their namespace under `onion.tor.example.com`. The concept of "rooting" a non-DNS context in a DNS context requires some explanation. This document tries to mitigate collisions in the DNS context. This means that if a name from the alternate naming system gets resolved in the DNS, it should not conflict or cause unexpected behavior. By "rooting a non-DNS context namespace in the DNS context, under a name controlled by the project" we mean that the rightmost set of labels should, if resolved in the DNS context be in a domain controlled by the developers / project. This means that, in the above example the software implementing the alternate namespace (browser plugins, custom stub resolvers, etc) would then match on names that end in the string `"onion.example.com"` and provide the alternate name resolution (instead of matching on the strings ending in `".onion"`.)

In a number of cases the purpose of the alternate name resolution system is to provide confidentiality. For these systems the above advice is problematic. If the a query for one of these names (for example `dissident.onion.example.com` (this is not a real `.onion` address)) were to leak into the DNS the query would hit the recursive resolver, and (assuming empty caches) would then hit the root, the `.com` name servers, the `example.com` name servers and then the `onion.example.com` nameservers. This means that the fact that a user is resolving `dissident.onion.example.com` would be visible to a large number of people. Furthermore, the `onion.example.com` nameservers

become a good oracle to determine what names exist, and who is trying to reach them.

For projects that are very latency sensitive, or which desire to provide confidentiality we recommend rooting the alternate namespace under the `.ALT` TLD.

## [5.](#) IANA Considerations

The IANA is requested to add the ALT string to the "Special-Use Domain Name" registry ([\[RFC6761\]](#)), and reference this document. In addition, the "Locally Served DNS Zones" ([\[RFC6303\]](#)) registry should be updated to reference this document.

## [6.](#) Security Considerations

One of the motivations for the creation of the alt pseudo-TLD is that unmanaged labels in the managed root name space are subject to unexpected takeover if the manager of the root name space decides to delegate the unmanaged label.

The unmanaged and registry-free nature of labels beneath .ALT provides the opportunity for an attacker to re-use the chosen label and thereby possibly compromise applications dependent on the special host name.

## [7.](#) Acknowledgements

The authors understand that there is much politics surrounding the delegation of a new TLD and thank the ICANN liaison (and any other poor sod who gets sucked into this) in advance.

#### [Appendix A](#). Changes / Author Notes.

[RFC Editor: Please remove this section before publication ]

From -01 to -02

- o Removed some fluffy wording, tightened up the language some.

From -00 to -01.

- o Fixed the abstract.
- o Recommended that folk root their non-DNS namespace under a DNS namespace that they control (Joe Abley)
