TRILL Resilient Distribution Trees draft-zhang-trill-resilient-trees-04.txt

Abstract

TRILL protocol provides layer 2 multicast data forwarding using IS-IS link state routing. Distribution trees are computed based on the link state information through Shortest Path First calculation. When a link on the distribution tree fails, a campus-wide recovergence of this distribution tree will take place, which can be time consuming and may cause considerable disruption to the ongoing multicast service.

This document proposes to build the backup distribution tree to protect links on the primary distribution tree. Since the backup distribution tree is built up ahead of the link failure, when a link on the primary distribution tree fails, the pre-installed backup forwarding table will be utilized to deliver multicast packets without waiting for the campus-wide recovergence, which minimizes the service disruption.

Status of this Memo

This Internet-Draft is submitted to IETF in full conformance with the provisions of $\underline{BCP 78}$ and $\underline{BCP 79}$.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

1. Introduction

Lots of multicast traffic is generated by interrupt latency sensitive applications, e.g., video distribution, including IP-TV, video conference and so on. Normally, a network fault will be recovered through a network wide reconvergence of the forwarding states, but this process is too slow to meet the tight Service Level Agreement (SLA) requirements on the service disruption duration. What is worse, updating multicast forwarding states may take significantly longer than unicast convergence since multicast states are updated based on control-plane signaling [mMRT].

Protection mechanisms are commonly used to reduce the service disruption caused by network faults. With backup forwarding states installed in advance, a protection mechanism is possible to restore an interrupted multicast stream in tens of milliseconds which quarantees the stringent SLA on service disruption. Several protection mechanisms for multicast traffic have been developed for IP/MPLS networks [mMRT] [MoFRR]. However, the way TRILL constructs distribution trees (DT) is different from the way multicast trees are computed under IP/MPLS, therefore a multicast protection mechanism suitable for TRILL is required.

This document proposes "Resilient Distribution Trees" (RDT) in which backup trees are installed in advance for the purpose of fast failure repair. Three types of protection mechanisms are proposed.

- o Global 1:1 protection is used to refer to the mechanism that the multicast source RBridge normally injects one multicast stream onto the primary DT. When interruption of this stream is detected, the source RBridge switches to the backup DT to inject subsequent multicast streams until the primary DT is recovered.
- o Global 1+1 protection is used to refer to the mechanism that the multicast source RBridge always injects two copies of multicast streams onto the primary DT and backup DT respectively. In the normal case, multicast receivers pick the stream sent along the primary DT and egress it to its local link. When a link failure interrupts the primary stream, the backup one will be picked until the primary DT is recovered.
- o Local protection refers to the mechanism that the RBridge attached to the failed link locally repairs the failure.

RDT may greatly reduce the service disruption caused by link failures. In the global 1:1 protection, the time cost by DT recalculation and installation can be saved. The global 1+1 protection and local protection further save the time spent on

failure propagation. A failed link can be repaired in tens of milliseconds. Although it's possible to make use of RDT to achieve load balance of multicast traffic, this document leaves that for future study.

[6326bis] defines the Affinity TLV. An "Affinity Link" can be explicitly assigned to a distribution tree or trees. This offers a way to manipulate the calculation of distribution trees. With intentional assignment of Affinity Links, a backup distribution tree can be set up to protect links on a primary distribution tree.

1.1. Conventions used in this document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in <u>RFC 2119</u> [<u>RFC2119</u>].

<u>1.2</u>. Terminology

IS-IS: Intermediate System to Intermediate System
TRILL: TRansparent Interconnection of Lots of Links
DT: Distribution Tree
RPF: Reverse Path Forwarding
RDT: Resilient Distribution Tree
SLA: Service Level Agreement
PLR: Point of Local Repair, in this document, it is the multicast
upstream RBridge connecting the failed link. It's valid only for
local protection.

2. Usage of Affinity Sub-TLV

This document uses the Affinity Sub-TLV [<u>6326bis</u>] to assign a parent to an RBridge in a tree as discussed below.

<u>2.1</u>. Allocating Affinity Links

Affinity Sub-TLV explicitly assigns parents for RBridges on distribution trees. They are advertised in the Affinity Sub-TLV and recognized by each RBridge in the campus. The originating RBridge becomes the parent and the nickname contained in the Affinity Record identifies the child. This explicitly provides an "Affinity Link" on a distribution tree or trees. The "Tree-num of roots" of the Affinity Record identify the distribution trees that adopt this Affinity Link [6326bis].

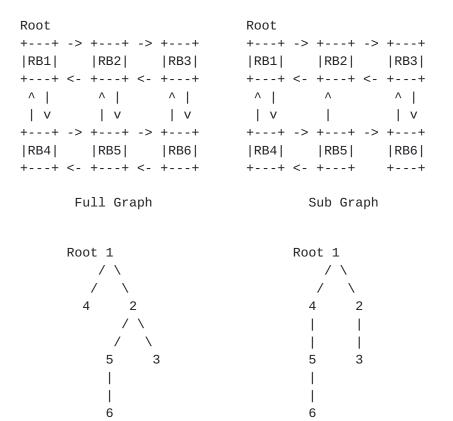

Affinity Links may be configured or automatically determined using a certain algorithm [CMT]. Suppose link RB2-RB3 is chosen as an Affinity Link on the distribution tree rooted at RB1. RB2 should send

out the Affinity Sub-TLV with an Affinity Record like {Nickname=RB3, Num of Trees=1, Tree-num of roots=RB1}. In this document, RB3 does not have to be a leaf node on a distribution tree, therefore an Affinity Link can be used to identify any link on a distribution tree. This kind of assignment offers a flexibility to RBridges in distribution tree calculation: they are allowed to choose child for which they are not on the shortest paths from the root. This flexibility is leveraged to increase the reliability of distribution trees in this document.

An Affinity Sub-TLV which tries to connect two RBridges that are not adjacent MUST be ignored.

2.2. Distribution Tree Calculation with Affinity Links

When RBridges receive an Affinity Sub-TLV with Affinity Link which is an incoming link of RB2 (i.e., RB2 is the child on this Affinity Link), RB2's incoming links other than the Affinity Link are removed from the full graph of the campus to get a sub graph. RBridges perform Shortest Path First calculation to compute the distribution tree based on the sub graph. In this way, the Affinity Link will surely appear on the distribution tree.

Shortest Path Tree of Full Graph Shortest Path Tree of Sub Graph

Figure 2.1: DT Calculation with the Affinity Link RB4-RB5

Take Figure 2.1 as an example. Suppose RB1 is the root and link RB4-RB5 is the Affinity Link. RB5's other incoming links RB2-RB5 and RB6-RB5 are removed from the Full Graph to get the Sub Graph. Since RB4-RB5 is the unique link to reach RB5, the Shortest Path Tree inevitably contains this link.

3. Resilient Distribution Trees Calculation

RBridges leverage IS-IS to detect and advertise network faults. A node or link failure will trigger a campus-wide reconvergence of distribution trees. The reconvergence generally includes the following procedures:

- 1. Failure detected through IS-IS control messages (HELLO) exchanging or some other method such as BFD [rbBFD];
- 2. IS-IS state flooding so each RBridge learns about the failure;
- 3. Each RBridge recalculates affected distribution trees independently;

 RPF filters are updated according to the new distribution trees. The recomputed distribution trees are pruned per VLAN and installed into the multicast forwarding tables.

The slow reconvergence can be as long as tens of seconds, which will cause disruption to ongoing multicast traffic. In protection mechanisms, alternative paths prepared ahead of potential node or link failures are used to detour the failures upon the failure detection, therefore service disruption can be minimized.

This document will focus only on link protection. The construction of backup DT for the purpose of node protection is out the scope of this document. In order to protect a node on the primary tree, a backup tree can be setup without this node [mMRT]. When this node fails, the backup tree can be safely used to forward multicast traffic to make a detour. However, TRILL distribution trees are shared among all VLANs and Fine Grained Labels [FGL] and they have to cover all RBridge nodes in the campus [RFC6325]. A DT that does not span all RBridges in the campus may not cover all receivers of many multicast groups. (This is different from the multicast trees construction signaled by PIM [RFC4601] or mLDP [RFC6388].)

<u>3.1</u>. Designating Roots for Backup Trees

Operators MAY manually configure the roots for the backup DTs. Nevertheless, this document aims to provide a mechanism with minimum configuration. Two options are offered as follows.

<u>3.1.1</u>. Conjugate Trees

[RFC6325] and [<u>ClearC</u>] has defined how distribution tree roots are selected. When a backup DT is computed for a primary DT, its root is set to be the root of this primary DT. In order to distinguish the primary DT and the backup DT, the root RBridge MUST own multiple nicknames.

3.1.2. Explicitly Advertising Tree Roots

RBridge RB1 having the highest root priority nickname might explicitly advertise a list of nicknames to identify the roots of the primary and backup tree roots (See <u>[RFC6325] Section 4.5</u>).

3.2. Backup DT Calculation

<u>3.2.1</u>. Backup DT Calculation with Affinity Links

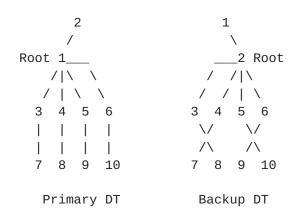

Figure 3.1: An Example of a Primary DT and its Backup DT

TRILL allows RBridges to compute multiple distribution trees. With the intentional assignment of Affinity Links in DT calculation, this document proposes a method to construct Resilient Distribution Trees (RDT). For example, in Figure 3.1, the backup DT is set up maximally disjoint to the primary DT (The full topology is a combination of these two DTs, which is not shown in the figure.). Except for the link between RB1 and RB2, all other links on the primary DT do not overlap with links on the backup DT. It means that every link on the primary DT, except link RB1-RB2, can be protected by the backup DT.

3.2.1.1. Algorithm for Choosing Affinity Links

Operators MAY configure Affinity Links to intentionally protect a specific link, such as the link connected to a gateway. But it is desirable that every RBridge independently computes Affinity Links for a backup DT across the whole campus. This enables a distributed deployment and also minimizes configuration.

Algorithms for Maximally Redundant Trees [mMRT] may be used to figure out Affinity Links on a backup DT which is maximally disjointed to the primary DT but it only provides a subset of all possible solutions, i.e., the conjugate trees described in <u>Section 3.1.1</u>. In TRILL, RDT does not restrict the root of the backup DT to be the same as that of the primary DT. Two disjoint (or maximally disjointed) trees may root from different nodes, which significantly augments the solution space.

This document RECOMMENDS achieving the independent method through a slight change to the conventional DT calculation process of TRILL. Basically, after the primary DT is calculated, the RBridge will be aware of which links will be used. When the backup DT is calculated, each RBridge increases the metric of these links by a proper value (for safety, it's recommended to used the summation of all original link metrics in the campus but not more than 2**23), which gives

these links a lower priority being chosen by the backup DT by performing Shortest Path First calculation. All links on this backup DT can be assigned as Affinity Links but this is unnecessary. In order to reduce the amount of Affinity Sub-TLVs flooded across the campus, only those not picked by conventional DT calculation process ought to be recognized as Affinity Links.

3.2.1.2. Affinity Links Advertisement

Similar to [CMT], every parent RBridge of an Affinity Link takes charge of announcing this link in an Affinity Sub-TLV. When this RBridge plays the role of parent RBridge for several Affinity Links, it is natural to have them advertised together in the same Affinity Sub-TLV and each Affinity Link is structured as one Affinity Record.

Affinity Links are announced in the Affinity Sub-TLV that is recognized by every RBridge. Since each RBridge computes distribution trees as the Affinity Sub-TLV requires, the backup DT will be built up consistently.

<u>3.2.2</u>. Backup DT Calculation without Affinity Links

This section provides an alternative method to set up the disjointed backup DT.

After the primary DT is calculated, each RBridge increases the cost of those links which are already in the primary DT by a multiplier (For safety, 64x is RECOMMENDED.). It would ensure that a link appears in both trees if and only if there is no other way to reach the node (i.e. the graph would become disconnected if it were pruned of the links in the first tree.). In other words, the two trees will be maximally disjointed.

The above algorithm is similar as that defined in <u>Section 3.2.1.1</u>. All RBridges MUST agree on the same algorithm, then the backup DT can be calculated by each RBridge consistently and configuration is unnecessary.

<u>4</u>. Resilient Distribution Trees Installation

As specified in [RFC6325] Section 4.5.2, an ingress RBridge MUST announce the distribution trees it may choose to ingress multicast frames. Thus other RBridges in the campus can limit the amount of states which are necessary for RPF check. Also, [RFC6325] recommends that an ingress RBridge by default chooses the DT or DTs whose root or roots are least cost from the ingress RBridge. To sum up, RBridges do pre-compute all the trees that might be used so they can properly forward multi-destination packets, but only install RPF state for

some combinations of ingress and tree.

This document states that the backup DT MUST be contained in an ingress RBridge's DT announcement list and included in this ingress RBridge's LSP. In order to reduce the service disruption time, RBridges SHOULD install backup DTs in advance, which also includes the RPF filters that need to be set up for RPF Check.

Since the backup DT is intentionally built up maximally disjointed to the primary DT, when a link fails and interrupts the ongoing multicast traffic sent along the primary DT, it is probable that the backup DT is not affected. Therefore, the backup DT installed in advance can be used to deliver multicast packets immediately.

4.1. Pruning the Backup Distribution Tree

The backup DT SHOULD be pruned per-VLAN. But the way a backup DT is pruned is different from the way that the primary DT is pruned. Even though a branch contains no downstream receivers, it is probable that it should not be pruned for the purpose of protection. The rule for backup DT pruning is that the backup DT should be pruned per-VLAN, eliminating branches that have no potential downstream RBridges which appear on the pruned primary DT.

It is probably that the primary DT is not optimally pruned in practice. In this case, the backup DT SHOULD be pruned presuming that the primary DT is optimally pruned. Those redundant links that ought to be pruned will not be protected.

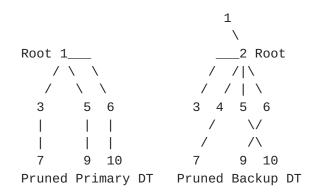

Figure 4.1: The Backup DT is Pruned Based on the Pruned Primary DT.

Suppose RB7, RB9 and RB10 constitute a multicast group MGx. The pruned primary DT and backup DT are shown in Figure 4.1. Referring back to Figure 3.1, branches RB2-RB1 and RB4-RB1 on the primary DT are pruned for the distribution of MGx traffic since there are no potential receivers on these two branches. Although branches RB1-RB2 and RB3-RB2 on the backup DT have no potential multicast receivers,

they appear on the pruned primary DT and may be used to repair link failures of the primary DT. Therefore they are not pruned from the backup DT. Branch RB8-RB3 can be safely pruned because it does not appear on the pruned primary DT.

4.2. RPF Filters Preparation

RB2 includes in its LSP the information to indicate which trees RB2 might choose to ingress multicast frames [RFC6325]. When RB2 specifies the trees it might choose to ingress multicast traffic, it SHOULD include the backup DT. Other RBridges will prepare the RPF check states for both the primary DT and backup DT. When a multicast packet is sent along either the primary DT or the backup DT, it will pass the RPF Check. This works when global 1:1 protection is used. However, when global 1+1 protection or local protection is applied, traffic duplication will happen if multicast receivers accept both copies of the multicast packets from two RPF filters. In order to avoid such duplication, egress RBridge multicast receivers MUST act as merge points to activate a single RPF filter and discard the duplicated packets from the other RPF filter. In normal case, the RPF state is set up according to the primary DT. When a link fails, the RPF filter based on the backup DT should be activated.

5. Protection Mechanisms with Resilient Distribution Trees

Protection mechanisms can be developed to make use of the backup DT installed in advance. But protection mechanisms already developed using PIM or mLDP for multicast of IP/MPLS networks are not applicable to TRILL due to the following fundamental differences in their distribution tree calculation.

- o The link on a TRILL distribution tree is bidirectional while the link on a distribution tree in IP/MPLS networks is unidirectional.
- o In TRILL, a multicast source node does not have to be the root of the distribution tree. It is just the opposite in IP/MPLS networks.
- o In IP/MPLS networks, distribution trees are constructed for each multicast source node as well as their backup distribution trees. In TRILL, a small number of core distribution trees are shared among multicast groups. A backup DT does not have to share the same root as the primary DT.

Therefore a TRILL specific multicast protection mechanism is needed.

Global 1:1 protection, global 1+1 protection and local protection are developed in this section. In Figure 4.1, assume RB7 is the ingress

RBridge of the multicast stream while RB9 and RB10 are the multicast receivers. Suppose link RB1-RB5 fails during the multicast forwarding. The backup DT rooted at RB2 does not include link RB1-RB5, therefore it can be used to protect this link. In global 1:1 protection, RB7 will switch the subsequent multicast traffic to this backup DT when it's notified about the link failure. In the global 1+1 protection, RB7 will inject two copies of the multicast stream and let multicast receivers RB9 and RB10 merge them. In the local protection, when link RB1-RB5 fails, RB1 will locally replicate the multicast traffic and send it on the backup DT.

5.1. Global 1:1 Protection

In the global 1:1 protection, the ingress RBridge of the multicast traffic is responsible for switching the failure affected traffic from the primary DT over to the backup DT. Since the backup DT has been installed in advance, the global protection need not wait for the DT recalculation and installation. When the ingress RBridge is notified about the failure, it immediately makes this switch over.

This type of protection is simple and duplication safe. However, depending on the topology of the RBridge campus, the time spent on the failure detection and propagation through the IS-IS control plane may still cause considerable service disruption.

BFD (Bidirectional Forwarding Detection) protocol can be used to reduce the failure detection time [rbBFD]. Link failures can be rapidly detected with one-hop BFD. Multi-destination BFD extends BFD mechanism to include the fast failure detection of multicast paths [mBFD]. It can be used to reduce both the failure detection and propagation time in the global protection. In multi-destination BFD, ingress RBridge need to send BFD control packets to poll each receiver, and receivers return BFD control packets to the ingress as response. If no response is received from a specific receiver for a detection time, the ingress can judge that the connectivity to this receiver is broken. In this way, multi-destination BFD detects the connectivity of a path rather than a link. The ingress RBridge will determine a minimum failed branch which contains this receiver. The ingress RBridge will switch ongoing multicast traffic based on this judgment. For example, on figure 4.1, if RB9 does not response while RB10 still responds, RB7 will presume that link RB1-RB5 and RB5-RB9 are failed. Multicast traffic will be switched to a backup DT that can protect these two links. Accurate link failure detection might help ingress RBridges to make smarter decision but it's out of the scope of this document.

5.2. Global 1+1 Protection

In the global 1+1 protection, the multicast source RBridge always replicates the multicast packets and sends them onto both the primary and backup DT. This may sacrifice the capacity efficiency but given there is much connection redundancy and inexpensive bandwidth in Data Center Networks, such kind of protection can be popular [MOFRR].

5.2.1. Failure Detection

Egress RBridges (merge points) SHOULD realize the link failure as early as possible so that failure affected egress RBridges may update their RPF filters quickly to minimize the traffic disruption. Three options are provided as follows.

- Egress RBridges assume a minimum known packet rate for a given data stream [MoFRR]. A failure detection timer Td are set as the interval between two continuous packets. Td is reinitialized each time a packet is received. If Td expires and packets are arriving at the egress RBridge on the backup DT (within the time frame Td), it updates the RPF filters and starts to receive packets forwarded on the backup DT.
- With multi-destination BFD, when a link failure happens, affected egress RBridges can detect a lack of connectivity from the ingress [mBFD]. Therefore these egress RBridges are able to update their RPF filters promptly.
- 3. Egress RBridges can always rely on the IS-IS control plane to learn the failure and determine whether their RPF filters should be updated.

<u>5.2.2</u>. Traffic Forking and Merging

For the sake of protection, transit RBridges SHOULD activate both primary and backup RPF filters, therefore both copies of the multicast packets will pass through transit RBridges.

Multicast receivers (egress RBridges) MUST act as "merge points" to egress only one copy of these multicast packets. This is achieved by the activation of only a single RPF filter. In normal case, egress RBridges activate the primary RPF filter. When a link on the pruned primary DT fails, ingress RBridge cannot reach some of the receivers. When these unreachable receivers realize it, they SHOULD update their RPF filters to receive packets sent on the backup DT.

5.3. Local Protection

In the local protection, the Point of Local Repair (PLR) happens at the upstream RBridge connecting the failed link. It is this RBridge

that makes the decision to replicate the multicast traffic to recover this link failure. Local protection can further save the time spent on failure notification through the flooding of LSPs across the campus. In addition, the failure detection can be speeded up using [rbBFD], therefore local protection can minimize the service disruption within 50 milliseconds.

Since the ingress RBridge is not necessarily the root of the distribution tree in TRILL, a multicast downstream point may not be the descendants of the ingress point on the distribution tree. Moreover, distribution trees in TRILL are bidirectional and do not share the same root. There are fundamental differences between the distribution tree calculation of TRILL and those used in PIM and mLDP, therefore local protection mechanisms used for PIM and mLDP, such as [mMRT] and [MoFRR], are not applicable here.

5.3.1. Start Using the Backup Distribution Tree

The egress nickname TRILL header field of the replicated multicast TRILL data packets specifies the tree on which they are being distributed. This field will be rewritten to the backup DT's root nickname by the PLR. But the ingress of the multicast frame MUST remain unchanged. This is a halfway change of the DT for multicast packets. Afterwards, the PLR begins to forward multicast traffic along the backup DT. This is a change from [RFC6325] which specifies that the egress nickname in the TRILL header of a multi-destination TRILL data packet must not be changed by transit RBridges.

In the above example, if PLR RB1 decides to send replicated multicast packets according to the backup DT, it will send it to the next hop RB2. .

5.3.2. Duplication Suppression

When a PLR starts to send replicated multicast packets on the backup DT, some multicast packets are still being sent along the primary DT. Some egress RBridges might receive duplicated multicast packets. The traffic forking and merging method in the global 1+1 protection can be adopted to suppress the duplication.

5.3.3. An Example to Walk Through

The example used in the above local protection is put together to get a whole "walk through" below.

In the normal case, multicast frames ingressed by RB7 with pruned distribution on primary DT rooted at RB1 are being received by RB9 and RB10. When the link RB1-RB5 fails, the PLR RB1 begins to

replicate and forward subsequent multicast packets using the pruned backup DT rooted at RB2. When RB2 gets the multicast packets from the link RB1-RB2, it accepts them since the RPF filter {DT=RB2, ingress=RB7, receiving links=RB1-RB2, RB3-RB2, RB4-RB2, RB5-RB2 and RB6-RB2} is installed on RB2. RB2 forwards the replicated multicast packets to its neighbors except RB1. When the multicast packets reach RB6 where both RPF filters {DT=RB1, ingress=RB7, receiving link=RB1-RB6} and {DT=RB2, ingress=RB7, receiving links=RB2-RB6 and RB9-RB6} are active. RB6 will let both multicast streams through. Multicast packets will finally reach RB9 where the RPF filter is updated from {DT=RB1, ingress=RB7, receiving link=RB5-RB9} to {DT=RB2, ingress=RB7, receiving link=RB6-RB9}. RB9 will egress the multicast packets on to the local link.

5.4. Switching Back to the Primary Distribution Tree

Assume an RBridge receives the LSP that indicates a link failure. This RBridge starts to calculate the new primary DT based on the topology with the failed link. Suppose the new primary DT is installed at t1.

The propagation of LSPs around the campus takes time. For safety, we assume all RBridges in the campus have converged to the new primary DT at t1+Ts. By default, Ts (the "settling time") is set to 30s but is configurable. At t1+Ts, the ingress RBridge switches the traffic from the backup DT back to the new primary DT.

After another Ts (at t1+2*Ts), no multicast packets are being forwarded along the old primary DT. The backup DT should be updated according to the new primary DT. The process of this update under different protection types are discussed as follows.

- a) For the global 1:1 protection, the backup DT is simply updated at t1+2*Ts.
- b) For the global 1+1 protection, the ingress RBridge stops replicating the multicast packets onto the old backup DT at t1+Ts. The backup DT is updated at t1+2*Ts. It MUST wait for another Ts, during which time period all RBridges converge to the new backup DT. At t1+3*Ts, the ingress RBridge MAY start to replicate multicast packets onto the new backup DT.
- c) For the local protection, the PLR stops replicating and sending packets on the old backup DT at t1+Ts. It is safe for RBridges to start updating the backup DT at t1+2*Ts.
- **<u>6</u>**. Security Considerations

This document raises no new security issues for TRILL.

For general TRILL Security Considerations, see [RFC6325].

7. IANA Considerations

No new registry or registry entries are requested to be assigned by IANA. The Affinity Sub-TLV has already been defined in [6326bis]. This document does not change its definition. RFC Editor: please remove this section before publication.
