Yang Data Model for BGP Protocol
draft-zhdankin-idr-bgp-cfg-00.txt

Abstract

This document defines a YANG data model that can be used to configure and manage BGP.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on July 30, 2015.

[1.](#) Introduction

YANG [[RFC6020](#)] is a data definition language that was introduced to define the contents of a conceptual data store that allows networked devices to be managed using NETCONF [[RFC6241](#)]. YANG is proving relevant beyond its initial confines, as bindings to other interfaces (e.g. ReST) and encodings other than XML (e.g. JSON) are being defined. Furthermore, YANG data models can be used as the basis of implementation for other interfaces, such as CLI and programmatic APIs.

This document defines a YANG data model that can be used to configure and manage BGP. The data model is very comprehensive in scope, resulting in a very large module being defined. When contemplating whether it would be appropriate to introduce a data model of such a large scope, we decided that there would be value in particular because BGP defines such a rich set of features, which makes the problem arising from heterogeneity involved when managing these features quite pronounced. Also, there is very little information that is designated as "mandatory", leaving the decision which capabilities to actually support to product implementations.

There are several distinct parts of the data model. The first part, by far the largest, serves to configure and manage BGP itself. It defines a large set of control knobs for that purpose, as well as a few data nodes that can be used to monitor health and gather statistics. The second part, much smaller than the first, defines a data model for the configuration of AS-Path and prefix-based filter lists, in essence policies that define the exchange of BGP messages between BGP peers. Together they form a complete data model that serves as a framework for configuration and management of BGP protocol and its policies.

The YANG module defined in this document has all the common building blocks for BGP protocol namely: Neighbor List, Address Family specific Parameters, Protocol Bestpath specific Parameters, Prefix

based Filter Lists, and AS-PATH based Filter Lists.

[1.1.](#) Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#) [[RFC2119](#)].

[2.](#) Definitions and Acronyms

AF: Address Family

AS: Autonomous System

BGP: Border Gateway Protocol

HTTP: Hyper-Text Transfer Protocol

JSON: JavaScript Object Notation

L2VPN: Layer 2 VPN

NETCONF: Network Configuration Protocol

NSAP: Network Service Access Point

ReST: Representational State Transfer, a style of stateless interface and protocol that is generally carried over HTTP

RPKI: Resource Public Key Infrastructure

RTFilter: Route Filter

VPN: Virtual Private Network

YANG: Data definition language for NETCONF

[3. The Design of the Core Routing Data Model](#)

[3.1. Overview](#)

The overall data model consists of two main components, each contained in its own separate container. Container "bgp-router" is used to configure and manage BGP itself. It is by far the largest part of the model. Container "prefix-lists" is used to configure BGP prefix lists. BGP prefix lists defines the rules and policies that helps BGP restrict information to share with which other nodes.

[3.2. BGP Router Configuration](#)

The overall structure of the "bgp-router" part of the model is depicted in the following diagram. Brackets enclose list keys, "rw" means configuration data, "?" designates optional nodes. The figure does not depict all definitions; it is intended to illustrate the overall structure.

```
module: bgp
  +--rw bgp-router
  |   +--rw bgp-version?          string
  |   +--rw local-as-number?      uint32
  |   +--rw local-as-identifier?  inet:ip-address
  |   +--rw rpki-config
  |   |   .....
  |   +--rw router-id
  |   |   .....
  |   +--rw af-configuration
  |   |   .....
  +--rw bgp-neighbors
  |   .....
  |   .....
```

The key components of the "bgp-router" model concern the configuration of the BGP neighbors, of the Resource Public Key Infrastructure (RPKI), and of address families (AF). Each is defined in the following subsections.

[3.2.1. AF Configuration](#)

AF-configuration is used to configure and manage BGP configuration on

an address family basis. BGP is designed to carry routing information for multiple different address families as specified in [RFC4760]. AF-Configuration is indexed by (router-AS, AFI, SAFI, VRFID) [RFC4760] and [RFC4364]. It contains any AF specific protocol configuration, BGP Bestpath configuration parameters, BGP neighbor configuration parameters, BGP dampening parameters, BGP route aggregation parameters, and any BGP policy configuration like redistribution.

The overall structure of the AF Configuration data model is depicted in the following diagram. As before, brackets enclose list keys, "rw" means configuration data, "?" designates optional nodes, parantheses indicate choices. The figure does not depict all definitions; it is intended to illustrate the overall model structure. Roughly speaking, address family configuration allows for separate configuration of IPv4, IPv6, L2VPN, NSAP, VPNv4 and VPNv6 address families, as well as route filters. Within each address family, you have additional substructure, for example, to distinguish between configuration of unicast and multicast.

```

|         |         | |     . . . . .

```

The key AF configuration components are described in the following subsections.

[3.2.1.1.](#) AF Specific Protocol Configuration

AF specific protocol configuration involves configuration of the parameters that are specific to a given AF. For instance, configuration parameters specific to the consistency checking between prefixes and labels are specific to address families that are enabled with Labels. Similarly redistribution of routes from other protocols is specific to Address Families that are supported in other protocols.

[3.2.1.2.](#) BGP Bestpath Configuration

BGP BestPath Configuration Parameters involves configuration of the parameters that influence the BGP Bestpath decision. For instance, the ignore-as-path command allows BGP process to ignore as-path length check. The ignore-routerid command allows BGP process to ignore routerid check. The ignore-igp-metric command allows BGP process to ignore igp metric check. The ignore-cost-community command allows BGP process to ignore cost communities. The MED related commands influence MED comparison in the BGP Bestpath decision.

[3.2.1.3.](#) BGP Neighbor Configuration

BGP Neighbor Configuration Parameters involves configuration of the parameters that are neighbor address family specific. These commands include neighbor capabilities, neighbor policies and any protocol related parameters that are specific to BGP neighbor.

[3.2.1.4.](#) BGP Dampening

BGP Dampening Parameters involves configuration of the parameters that influence BGP Route Dampening. These parameters allow enabling of Route Dampening on an address family level. The Dampening configuration also allows configuration of Dampening specific parameters like max suppress time, reuse threshold, half life, and the suppress threshold.

[3.2.1.5.](#) BGP Route Aggregation

BGP Route Aggregation Parameters involves configuration of the parameters that enables BGP Route Aggregation.

[3.2.1.6.](#) BGP Redistribution

BGP Route Redistribution Parameters involves configuration of the parameters that enables BGP Route Redistribution from and to the BGP protocol.

[3.2.2.](#) BGP Neighbor Configuration

Bgp-neighbor is used to configure and manage BGP neighbors. BGP neighbor configuration is indexed by af-configuration, neighbor address and neighbor-AS. It contains configuration for any policies that are configured for a neighbor on an inbound or an outbound, any transport related configuration parameters, any protocol related configuration parameters, and any protocol capabilities related configuration parameters.

BGP-neighbor-groups are used to configure and manage set of BGP neighbors with common configuration. BGP-neighbor-groups are indexed by af-configuration and group-name.

The following diagram depicts the overall structure of the BGP Neighbors subtree. Brackets enclose list keys, "rw" means configuration, "ro" operational state data, and "?" designates optional nodes. Parentheses enclose choice and case nodes. The figure does not depict all definitions; it is intended to illustrate the overall structure.

```

routes.

The structure of the RPKI configuration data model is depicted below, per the same conventions used in the earlier diagrams.

```
module: bgp
  +--rw bgp-router
  |   ....
  |   +--rw rpki-config
  |   |   +--rw cache-server-config
  |   |   |   ....
  |   |   +--rw validation-config
  |   |   |   ....
  |   |   +--rw bestpath-computation
  |   |   ....
```

[3.3.](#) Prefix Lists

BGP Prefix Lists are used to manipulate Prefix information carried within a BGP. The prefix information carried within BGP is filtered or allowed using BGP Prefix Lists. BGP Prefix Lists consists of an ordered set of one or more rules that describe IPv4 or IPv6 prefixes range and an associated action rule that describes whether the matching prefixes should be dropped or permitted. The Prefix Lists are usually applied to a BGP neighbor as part of an inbound policy (applied to prefixes received by a neighbor) or an outbound policy (applied to prefixes sent by a neighbor).

The structure of the prefix list configuration data model is depicted below, per the same conventions used in the earlier diagrams.

```
module: bgp
  ....
  +--rw prefix-lists
  |   +--rw prefix-list [prefix-list-name]
  |   |   +--rw prefix-list-name    string
  |   |   +--rw prefixes
  |   |   |   +--rw prefix [seq-nr]
  |   |   |   |   +--rw seq-nr          uint16
  |   |   |   |   +--rw prefix-filter
  |   |   |   |   +--rw (ip-address-group)?
```

```

| .....
+--rw action                actions-enum
+--rw statistics
    .....

```

Prefix lists are defined in a list in a designated container. Each prefix list in turn contains a list of prefixes, indexed by a sequence number. Each prefix is comprised of a prefix filter, used to match BGP packets, an action that is applied when a filter matches, and a set of statistics that indicate how often individual prefixes are applied.

[4.](#) BGP Yang Module

<CODE BEGINS> file "bgp@2013-07-15.yang"

```

module bgp {
  namespace "urn:cisco:params:xml:ns:yang:bgp";
  // replace with IANA namespace when assigned
  prefix bgp;
