Yang Data Model for Bidirectional Forwarding Detection (BFD)
draft-zheng-bfd-yang-03.txt

Abstract

This document defines a YANG data model that can be used to configure and manage Bidirectional Forwarding Detection (BFD).

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#) [[RFC2119](#)].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on December 11, 2015.

[1. Introduction](#)

YANG [[RFC6020](#)] is a data definition language that was introduced to define the contents of a conceptual data store that allows networked devices to be managed using NETCONF [[RFC6241](#)]. YANG is proving relevant beyond its initial confines, as bindings to other interfaces (e.g RESTCONF [[I-D.ietf-netconf-restconf](#)]) and encodings other than XML (e.g JSON) are being defined. Furthermore, YANG data models can be used as the basis of implementation for other interfaces, such as CLI and programmatic APIs.

This document defines a YANG data model that can be used to configure and manage Bidirectional Forwarding Detection (BFD)[[RFC5880](#)]. BFD is a network protocol which is used for liveness detection of arbitrary paths between systems. Some examples of different types of paths over which we have BFD:

- 1) Two systems directly connected via IP. This is known as BFD over single-hop IP [[RFC5881](#)]
- 2) Two systems connected via multiple hops [[RFC5883](#)]
- 3) Two systems connected via MPLS Label Switched Paths (LSPs)
[[RFC5884](#)]
- 4) Two systems connected via a Link Aggregation Group (LAG) interface
[[RFC7130](#)]

BFD typically does not operate on its own. Various control protocols, aka BFD clients, use the services provided by BFD for their own operation [[RFC5882](#)]. The obvious candidates which use BFD are those which do not have Hellos to detect failures (e.g. static routes) and routing protocols whose Hellos do not support sub-second failure detection, e.g OSPF and IS-IS.

[Page 3]

2.1. Design of configuration model

The configuration model consists mainly of the parameters specified in [[RFC5880](#)]. Some examples are desired minimum transmit interval, required minimum receive interval, detection multiplier etc

Some implementations have BFD configuration under the BFD client, e.g. BFD configuration is under routing applications such as OSPF, IS-IS, BGP etc. Other implementations have BFD configuration centralized, i.e outside the multiple BFD clients. In the sections below we address both approaches.

2.1.1. Centralized BFD configuration

The BFD data model consists of configuring BFD sessions of different types (e.g. single-hop IP, multi-hop IP etc). Since the different session types have different keys we have a list per session type, but we use a grouping to share the common configuration data between the different session types.

2.1.1.1. Common BFD configuration

The common BFD session configuration items are put in a grouping to be used in multiple places, these items are:

`local-multiplier`

This is the detection time multiplier as defined in [[RFC5880](#)].

`desired-min-tx-interval`

This is the Desired Min TX Interval as defined in [[RFC5880](#)].

`required-min-rx-interval`

This is the Required Min RX Interval as defined in [[RFC5880](#)].

`demand-enabled`

Set to True to enable demand mode as defined in [[RFC5880](#)].

`enable-authentication`

Set to True to enable BFD authentication.

`authentication-algorithm`

Authentication algorithm to use (if enabled).

`key-chain-name`

Key-chain to be used for authentication (if enabled).

Zheng, et al.

Expires December 11, 2015

[Page 4]

2.1.1.2. Single-hop IP

We have a list for BFD sessions over single-hop IP. The key consists of:

interface

This is the interface on which the BFD packets for this session are transmitted and received. Examples of an interface are physical media, virtual circuit, tunnel etc.

destination address

Address belonging to the peer system as per [[RFC5881](#)]

The common configuration data in [Section 2.1.1.1](#) is used for single-hop IP. On top of that common data, we also need configuration data for echo:

desired-min-echo-tx-interval

This is the minimum interval that the local system would like to use when transmitting BFD echo packets. If 0 the echo function as defined in [[RFC5880](#)] is disabled.

required-min-echo-rx-interval

The is the Required Min Echo RX Interval as defined in [[RFC5880](#)].

2.1.1.3. Multi-hop IP

We have a list for BFD sessions over multi-hop IP. The key consists of:

source address

Address belonging to the local system as per [[RFC5883](#)]

destination address

Address belonging to the remote system as per [[RFC5883](#)]

VRF name

VRF in which the BFD multi-hop session is running

The common configuration data in [Section 2.1.1.1](#) is used for multi-hop IP. On top of that common data, we also need TTL:

ttl

TTL of outgoing BFD control packets.

[Page 5]

[2.1.1.4. MPLS LSP](#)

TBD

[2.1.1.5. Link Aggregation Group](#)

TBD

[2.1.1.6. Per-interface configuration](#)

For implementations which have multiplier and intervals configured under the BFD clients we still need a central location to configure authentication, demand mode etc. This can be done by configuring the following parameters per interface:

Common parameters

The common BFD parameters listed in [Section 2.1.1.1](#)

Echo parameters

The echo parameters listed in [Section 2.1.1.2](#)

[2.1.2. Configuration in BFD clients](#)

When BFD is configured in BFD clients, it is highly desirable to have BFD configuration consistency between those clients. In this approach we have a grouping for BFD configuration which applications can import in their YANG module:

- This provides consistency since the same grouping is being used in all applications making use of BFD
- Since not all implementations of those BFD clients have support for BFD, we must use if-feature in the respective YANG modules

An application importing the BFD configuration grouping could do so in a hierarchical manner if it has multiple levels at which BFD configuration can be applied. In a subsequent section we provide an example of how a BFD client would use the grouping in such a way.

The configuration items are:

enabled

Set to True to enable BFD.

local-multiplier

This the detection time multiplier as defined in [[RFC5880](#)].

desired-min-tx-interval

Zheng, et al.

Expires December 11, 2015

[Page 6]

This the Desired Min TX Interval as defined in [[RFC5880](#)].

required-min-rx-interval

This the Required Min RX Interval as defined in [[RFC5880](#)].

2.2. Design of operational model

The operational model contains both the overall statistics of BFD sessions running on the device and the per session operational statistics. Since BFD is used for liveness detection of arbitrary paths, there is no uniform key to identify a BFD session. e.g. a BFD single-hop IP session is uniquely identified by the combination of destination IP address and interface whereas a multihop IP session is uniquely identified by the combination of source IP address, destination IP address and VRF. For this reason, for per session operational statistics, we do not have a single list with different type BFD sessions. Instead we have a container in which we have multiple lists, where each list corresponds to one specific path type for BFD. For example we have one operational list for BFD single-hop IP, another list for BFD multi-hop IP etc. In each list, mainly three categories of operational items are shown. The fundamental information of a BFD session such as the local discriminator, remote discriminator and the capability of supporting demand detect mode are shown in the first category. A second category includes a BFD session running information, e.g. the FSM the device in and diagnostic code received. Another example is the actual transmit interval between the control packets, which may be different from the desired minimum transmit interval configured, is shown in this category. Similar examples are actual received interval between the control packets and the actual transmit interval between the echo packets. The third category contains the detailed statistics of this session, e.g. when the session went to up/down, how long it has been since the session is up/down.

2.3. Notifications

This YANG model defines a list of notifications to inform clients of BFD with important events detected during the protocol operation. Pair of local and remote discriminator identifies a BFD session on local system. Notification also give more important details about BFD sessions e.g. new state, time in previous state, VRF and reason for BFD session state changed.

2.4. RPC Operations

TBD

2.5. BFD Configuration Data Hierarchy

2.5.1. Centralized BFD configuration

The following is the centralized configuration data hierarchy:

We have a container which contains a list for each session type

We have per-interface configuration

```
module: ietf-bfd
++-rw bfd
  +-rw bfd-cfg
    | +-rw bfd-session-cfg {bfd-centralized-session-config}?
    | | +-rw session-ip-sh* [interface dest-addr]
    | | | +-rw interface                               if:interface-ref
    | | | +-rw dest-addr                             inet:ip-address
    | | | +-rw admin-down?                           boolean
    | | | +-rw local-multiplier?                   multiplier
    | | | +-rw desired-min-tx-interval          uint32
    | | | +-rw required-min-rx-interval          uint32
    | | | +-rw demand-enabled?                  boolean
    | | | +-rw enable-authentication?           boolean
    | | | +-rw authentication-parms {bfd-authentication}?
    | | | | +-rw key-chain-name?             string
    | | | | +-rw algorithm?                 bfd-auth-algorithm
    | | | +-rw desired-min-echo-tx-interval   uint32
    | | | +-rw required-min-echo-rx-interval   uint32
    | | +-rw session-ip-mh* [vrf-name source-addr dest-addr]
    | | | +-rw vrf-name                     vrfName
    | | | +-rw source-addr                  inet:ip-address
    | | | +-rw dest-addr                   inet:ip-address
    | | | +-rw admin-down?                boolean
    | | | +-rw local-multiplier?          multiplier
    | | | +-rw desired-min-tx-interval      uint32
    | | | +-rw required-min-rx-interval      uint32
    | | | +-rw demand-enabled?            boolean
    | | | +-rw enable-authentication?       boolean
    | | | +-rw authentication-parms {bfd-authentication}?
    | | | | +-rw key-chain-name?           string
    | | | | +-rw algorithm?                 bfd-auth-algorithm
    | | | +-rw tx-ttl?                      TTL
    | | | +-rw rx-ttl?                      TTL
    +-rw bfd-interface-cfg* [interface] {bfd-interface-config}?
      +-rw interface                           if:interface-ref
      +-rw local-multiplier?                 multiplier
      +-rw desired-min-tx-interval          uint32
      +-rw required-min-rx-interval          uint32
      +-rw demand-enabled?                 boolean
      +-rw enable-authentication?           boolean
      +-rw authentication-parms {bfd-authentication}?
        | +-rw key-chain-name?             string
        | +-rw algorithm?                 bfd-auth-algorithm
      +-rw desired-min-echo-tx-interval      uint32
      +-rw required-min-echo-rx-interval      uint32
```

[Page 9]

[2.5.2. Configuration in BFD clients](#)

The following is the configuration data hierarchy for a hypothetical BFD client called `bfd-routing-app`, the BFD configuration is supported conditionally via use of `if-feature`.

We have a list of areas and in each area we have a list of interfaces. The BFD configuration grouping is used in a hierarchical fashion, it can be applied in "area" and "interface":

- If BFD configuration is applied under an interface, that configuration takes precedence over any BFD configuration (if any) at the area level
- If BFD configuration is applied under an "area" and none of the interfaces in that area has BFD configuration, then all interfaces belong to the "area" in question inherit the BFD configuration for the area in question.
- If the BFD client implementation supports "interface all", then all the interfaces belonging to that area will inherit the BFD configuration under "interface all". Along with this if there are specific interface configuration then specific interface will override the "interface all" parameters.

```
module: bfd-routing-app
  +-rw area* [area-id]
    +-rw area-id      uint32
    +-rw bfd-cfg
      |  +-rw enabled?          boolean
      |  +-rw local-multiplier? multiplier
      |  +-rw desired-min-tx-interval  uint32
      |  +-rw required-min-rx-interval  uint32
    +-rw interface* [interface]
      +-rw interface    if:interface-ref
      +-rw bfd-cfg
        +-rw enabled?          boolean
        +-rw local-multiplier? multiplier
        +-rw desired-min-tx-interval  uint32
        +-rw required-min-rx-interval  uint32
```

[2.6. Operational Data Hierarchy](#)

The complete data hierarchy of BFD YANG operational model is presented below.

```
module: ietf-bfd
  +-rw bfd
    +--ro bfd-oper
      +--ro bfd-session-statistics
        |  +-ro ip-sh-session-num?  uint32
        |  +-ro ip-mh-session-num?  uint32
        |  +-ro total-session-num?  uint32
        |  +-ro session-up-num?     uint32
        |  +-ro sess-down-num?     uint32
      +--ro bfd-session-lists
        +--ro session-ip-sh* [interface dest-addr]
          |  +-ro interface           if:interface-ref
          |  +-ro dest-addr            inet:ip-address
          |  +-ro session-type?       enumeration
          |  +-ro local-discriminator? discriminator
          |  +-ro remote-discriminator? discriminator
          |  +-ro remote-multiplier?   multiplier
          |  +-ro out-interface?      if:interface-ref
          |  +-ro demand-capability?  boolean
          |  +-ro session-running*
            |  |  +-ro local-state?      state
            |  |  +-ro remote-state?     state
            |  |  +-ro local-diagnostic? diagnostic
            |  |  +-ro remote-diagnostic? diagnostic
            |  |  +-ro detect-Mode?      enumeration
            |  |  +-ro actual-tx-interval? uint32
            |  |  +-ro actual-rx-interval? uint32
            |  |  +-ro actual-echo-tx-interval? uint32
            |  |  +-ro detect-time?      uint32
          |  +-ro session-statistics*

2.12. Security Considerations

The YANG module defined in this memo is designed to be accessed via the NETCONF protocol [[RFC6241](#)]. The lowest NETCONF layer is the secure transport layer and the mandatory to implement secure transport is SSH [[RFC6242](#)]. The NETCONF access control model [[RFC6536](#)] provides the means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

The YANG module has writeable data nodes which can be used for creation of BFD sessions and modification of BFD session parameters. The system should "police" creation of BFD sessions to prevent new sessions from causing existing BFD sessions to fail. For BFD session modification, the BFD protocol has mechanisms in place which allow for in service modification.

[**2.13. IANA Considerations**](#)

The IANA is requested to assign a new namespace URI from the IETF XML registry.

URI:TBD
