Network Access Control List (ACL) YANG Data Model  
draft-ietf-netmod-acl-model-14

Abstract

This document describes a data model of Access Control List (ACL) basic building blocks.

Editorial Note (To be removed by RFC Editor)

This draft contains many placeholder values that need to be replaced with finalized values at the time of publication. This note summarizes all of the substitutions that are needed. Please note that no other RFC Editor instructions are specified anywhere else in this document.

Artwork in this document contains shorthand references to drafts in progress. Please apply the following replacements

- o "XXXX" --> the assigned RFC value for this draft both in this draft and in the YANG models under the revision statement.
- o Revision date in model needs to get updated with the date the draft gets approved. The date also needs to get reflected on the line with <CODE BEGINS>.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 6, 2018.

## 1. Introduction

Access Control List (ACL) is one of the basic elements used to configure device forwarding behavior. It is used in many networking technologies such as Policy Based Routing, Firewalls etc.

An ACL is an ordered set of rules that is used to filter traffic on a networking device. Each rule is represented by an Access Control Entry (ACE).

Each ACE has a group of match criteria and a group of action criteria.

The match criteria consist of a tuple of packet header match criteria and can have metadata match criteria as well.

- o Packet header matches apply to fields visible in the packet such as address or class of service or port numbers.
- o In case vendor supports it, metadata matches apply to fields associated with the packet but not in the packet header such as input interface or overall packet length

The actions specify what to do with the packet when the matching criteria is met. These actions are any operations that would apply to the packet, such as counting, policing, or simply forwarding. The list of potential actions is endless depending on the capabilities of the networked devices.

Access Control List is also widely known as ACL (pronounce as [ak-uh l]) or Access List. In this document, Access Control List, ACL and Access List are used interchangeably.

The matching of filters and actions in an ACE/ACL are triggered only after application/attachment of the ACL to an interface, VRF, vty/tty session, QoS policy, routing protocols amongst various other config attachment points. Once attached, it is used for filtering traffic using the match criteria in the ACE's and taking appropriate action(s) that have been configured against that ACE. In order to apply an ACL to any attachment point, vendors would have to augment the ACL YANG model.

### 1.1. Definitions and Acronyms

ACE: Access Control Entry

ACL: Access Control List

DSCP: Differentiated Services Code Point

ICMP: Internet Control Message Protocol

IP: Internet Protocol

IPv4: Internet Protocol version 4

IPv6: Internet Protocol version 6

MAC: Media Access Control

TCP: Transmission Control Protocol

## 2. Problem Statement

This document defines a YANG [RFC6020] data model for the configuration of ACLs. It is very important that model can be easily used by applications/attachments.

ACL implementations in every device may vary greatly in terms of the filter constructs and actions that they support. Therefore this draft proposes a model that can be augmented by standard extensions and vendor proprietary models.

## 3. Understanding ACL's Filters and Actions

Although different vendors have different ACL data models, there is a common understanding of what access control list (ACL) is. A network system usually have a list of ACLs, and each ACL contains an ordered list of rules, also known as access list entries - ACEs. Each ACE has a group of match criteria and a group of action criteria. The match criteria consist of packet header matching. It is also possible for ACE to match on metadata, if supported by the vendor. Packet header matching applies to fields visible in the packet such as address or class of service or port numbers. Metadata matching applies to fields associated with the packet, but not in the packet header such as input interface, packet length, or source or destination prefix length. The actions can be any sort of operation from logging to rate limiting or dropping to simply forwarding. Actions on the first matching ACE are applied with no processing of subsequent ACEs.

The model also includes a container to hold overall operational state for each ACL and operational state for each ACE. One ACL can be applied to multiple targets within the device, such as interfaces of a networked device, applications or features running in the device, etc. When applied to interfaces of a networked device, the ACL is

applied in a direction which indicates if it should be applied to packet entering (input) or leaving the device (output). An example in the appendix shows how to express it in YANG model.

This draft tries to address the commonalities between all vendors and create a common model, which can be augmented with proprietary models. The base model is simple and with this design we hope to achieve enough flexibility for each vendor to extend the base model. The use of feature statements in the document allows vendors to advertise match rules they support.

### 3.1. ACL Modules

There are two YANG modules in the model. The first module, "ietf-access-control-list", defines generic ACL aspects which are common to all ACLs regardless of their type or vendor. In effect, the module can be viewed as providing a generic ACL "superclass". It imports the second module, "ietf-packet-fields". The match container in "ietf-access-control-list" uses groupings in "ietf-packet-fields". The combination of if-feature checks and must statements allow for the selection of relevant match fields that a user can define rules for.

If there is a need to define new "matches" choice, such as IPFIX [RFC5101], the container "matches" can be augmented.

For a reference to the annotations used in the diagram below, see YANG Tree Diagrams [I-D.ietf-netmod-yang-tree-diagrams].

#### 4. ACL YANG Models

##### 4.1. IETF Access Control List module

"ietf-access-control-list" is the standard top level module for access lists. The "access-lists" container stores a list of "acl". Each "acl" has information identifying the access list by a name("acl-name") and a list("access-list-entries") of rules associated with the "acl-name". Each of the entries in the list("access-list-entries"), indexed by the string "rule-name", has containers defining "matches" and "actions".

The model uses defines several ACL types in the form of identities and features. Features are used by implementors to select the ACL types the system can support. These types are implicitly inherited by the "ace", thus safeguarding against misconfiguration of "ace" types in an "acl".

The "matches" define criteria used to identify patterns in "ietf-packet-fields". The "actions" define behavior to undertake once a "match" has been identified. In addition to permit and deny for actions, a logging option allows for a match to be logged that can be used to determine which rule was matched upon. The model also defines the ability for ACL's to be attached to a particular interface.

Statistics in the ACL can be collected for an "ace" or for an "interface". The feature statements defined for statistics can be used to determine whether statistics are being collected per "ace", per "interface" or both.

<CODE ENDS>

#### 4.2. IETF Packet Fields module

The packet fields module defines the necessary groups for matching on fields in the packet including ethernet, ipv4, ipv6, and transport layer fields. The 'acl-type' node determines which of these fields get included for any given ACL with the exception of TCP, UDP and ICMP header fields. Those fields can be used in conjunction with any of the above layer 2 or layer 3 fields.

Since the number of match criteria is very large, the base draft does not include these directly but references them by "uses" to keep the base module simple. In case more match conditions are needed, those can be added by augmenting choices within container "matches" in ietf-access-control-list.yang model.

<CODE BEGINS> file "ietf-packet-fields@2017-10-03.yang"

```

module ietf-packet-fields {
    namespace "urn:ietf:params:xml:ns:yang:ietf-packet-fields";

}

```

<CODE ENDS>

#### 4.3. An ACL Example

Requirement: Deny tcp traffic from 10.10.10.1/24, destined to 11.11.11.1/24.

Here is the acl configuration xml for this Access Control List:

```
<?xml version='1.0' encoding='UTF-8'?>
  <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <access-lists xmlns="urn:ietf:params:xml:ns:yang:
      ietf-access-control-list">
      <acl>
        <acl-name>sample-ipv4-acl</acl-name>
        <acl-type>ipv4-acl</acl-type>
        <aces>
          <ace>
            <rule-name>rule1</rule-name>
            <matches>
              <ipv4-acl>
                <protocol>tcp</protocol>
                <destination-ipv4-network>
                  11.11.11.1/24
                </destination-ipv4-network>
                <source-ipv4-network>
                  10.10.10.1/24
                </source-ipv4-network>
              </ipv4-acl>
            </matches>
            <actions>
              <packet-handling>deny</packet-handling>
            </actions>
          </ace>
        </aces>
      </acl>
    </access-lists>
  </data>
```

The acl and aces can be described in CLI as the following:

```
access-list ipv4 sample-ipv4-acl
deny tcp 10.10.10.1/24 11.11.11.1/24
```

#### 4.4. Port Range Usage Example

When a lower-port and an upper-port are both present, it represents a range between lower-port and upper-port with both the lower-port and upper-port are included. When only a lower-port presents, it represents a single port.

With the follow XML snippet:

```
<source-port-range>
  <lower-port>16384</lower-port>
  <upper-port>16387</upper-port>
</source-port-range>
```

This represents source ports 16384,16385, 16386, and 16387.

With the follow XML snippet:

```
<source-port-range>
  <lower-port>16384</lower-port>
  <upper-port>65535</upper-port>
</source-port-range>
```

This represents source ports greater than/equal to 16384 and less than equal to 65535.

With the follow XML snippet:

```
<source-port-range>
  <lower-port>21</lower-port>
</source-port-range>
```

This represents port 21.

With the following XML snippet, the configuration is specifying all ports that are not equal to 21.

```
<source-port-range>
  <lower-port>21</lower-port>
  <operations>neq</operations>
</source-port-range>
```

## 5. Security Considerations

The YANG module defined in this memo is designed to be accessed via the NETCONF [RFC6241]. The lowest NETCONF layer is the secure transport layer and the mandatory-to-implement secure transport is SSH [RFC6242]. The NETCONF Access Control Model ( NACM [RFC6536]) provides the means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

There are a number of data nodes defined in the YANG module which are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., <edit-config>)

to these data nodes without proper protection can have a negative effect on network operations.

These are the subtrees and data nodes and their sensitivity/vulnerability:

/access-lists/acl/access-list-entries: This list specifies all the configured access list entries on the device. Unauthorized write access to this list can allow intruders to access and control the system. Unauthorized read access to this list can allow intruders to spoof packets with authorized addresses thereby compromising the system.

## 6. IANA Considerations

This document registers a URI in the IETF XML registry [RFC3688]. Following the format in RFC 3688, the following registration is requested to be made:

URI: urn:ietf:params:xml:ns:yang:ietf-access-control-list

URI: urn:ietf:params:xml:ns:yang:ietf-packet-fields

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

This document registers a YANG module in the YANG Module Names registry [RFC6020].

name: ietf-access-control-list namespace:  
urn:ietf:params:xml:ns:yang:ietf-access-control-list prefix: ietf-acl  
reference: RFC XXXX

name: ietf-packet-fields namespace: urn:ietf:params:xml:ns:yang:ietf-packet-fields prefix: ietf-packet-fields reference: RFC XXXX

## 7. Acknowledgements

Alex Clemm, Andy Bierman and Lisa Huang started it by sketching out an initial IETF draft in several past IETF meetings. That draft included an ACL YANG model structure and a rich set of match filters, and acknowledged contributions by Louis Fourie, Dana Blair, Tula Kraiser, Patrick Gili, George Serpa, Martin Bjorklund, Kent Watsen, and Phil Shafer. Many people have reviewed the various earlier drafts that made the draft went into IETF charter.

Dean Bogdanovic, Kiran Agrahara Sreenivasa, Lisa Huang, and Dana Blair each evaluated the YANG model in previous drafts separately, and then worked together to create a ACL draft that was supported by different vendors. That draft removed vendor specific features, and gave examples to allow vendors to extend in their own proprietary ACL. The earlier draft was superseded with this updated draft and received more participation from many vendors.

Authors would like to thank Jason Sterne, Lada Lhotka, Juergen Schoenwalder, David Bannister, and Jeff Haas for their review of and suggestions to the draft.

## 8. Open Issues

- o The current model does not support the concept of "containers" used to contain multiple addresses per rule entry.

## Appendix A. Extending ACL model examples

### A.1. Example of extending existing model for route filtering

With proposed modular design, it is easy to extend the model with other features. Those features can be standard features, like route filters. Route filters match on specific IP addresses or ranges of prefixes. Much like ACLs, they include some match criteria and corresponding match action(s). For that reason, it is very simple to extend existing ACL model with route filtering. The combination of a route prefix and prefix length along with the type of match determines how route filters are evaluated against incoming routes. Different vendors have different match types and in this model we are using only ones that are common across all vendors participating in this draft. As in this example, the base ACL model can be extended with company proprietary extensions, described in the next section.

```
module: example-ext-route-filter
  augment /ietf-acl:access-lists/ietf-acl:acl/ietf-acl:aces/ietf-acl:ace/ietf-acl:matches:
    +--rw (route-prefix)?
      +--:(range)
        +--rw (ipv4-range)?
          | +--:(v4-lower-bound)
          | | +--rw v4-lower-bound?   inet:ipv4-prefix
          | +--:(v4-upper-bound)
          | | +--rw v4-upper-bound?   inet:ipv4-prefix
        +--rw (ipv6-range)?
          | +--:(v6-lower-bound)
          | | +--rw v6-lower-bound?   inet:ipv6-prefix
          | +--:(v6-upper-bound)
          | | +--rw v6-upper-bound?   inet:ipv6-prefix

```

### A.2. A company proprietary module example

Module "example-newco-acl" is an example of company proprietary model that augments "ietf-acl" module. It shows how to use 'augment' with an XPath expression to add additional match criteria, action criteria, and default actions when no ACE matches found. All these are company proprietary extensions or system feature extensions. "example-newco-acl" is just an example and it is expected from vendors to create their own proprietary models.

The following figure is the tree structure of example-newco-acl. In this example, /ietf-acl:access-lists/ietf-acl:acl/ietf-acl:aces/ietf-acl:ace/ietf-acl:matches are augmented with two new choices, protocol-payload-choice and metadata. The protocol-payload-choice uses a grouping with an enumeration of all supported protocol values. Metadata matches apply to fields associated with the packet but not in the packet header such as overall packet length. In other example, /ietf-acl:access-lists/ietf-acl:acl/ietf-acl:aces/ietf-acl:ace/ietf-acl:actions are augmented with new choice of actions.

```

module: example-newco-acl
  augment /ietf-acl:access-lists/ietf-acl:acl/ietf-acl:aces/ietf-acl:ace/ietf-acl:matches:
    +--rw (protocol-payload-choice)?
    |   +--:(protocol-payload)
    |   |   +--rw protocol-payload* [value-keyword]
    |   |   +--rw value-keyword      enumeration
    +--rw (metadata)?
    |   +--:(packet-length)
    |   |   +--rw packet-length?      uint16
  augment /ietf-acl:access-lists/ietf-acl:acl/ietf-acl:aces/ietf-acl:ace/ietf-acl:actions:
    +--rw (action)?
    |   +--:(count)
    |   |   +--rw count?              string
    |   +--:(policer)
    |   |   +--rw policer?            string
    |   +--:(hierarchical-policer)
    |   |   +--rw hierarchitacl-policer? string
  augment /ietf-acl:access-lists/ietf-acl:acl:
    +--rw default-actions
    +--rw deny?      empty

            enum icmp {
                description "Internet Control Message Protocol";
            }
            enum icmp6 {
                description "Internet Control Message Protocol Version 6";
            }
            enum range {
                description "Range of values";
            }
        }
        description "(null)";
    }
}
}

```

Draft authors expect that different vendors will provide their own yang models as in the example above, which is the augmentation of the base model

### A.3. Linux nftables

As Linux platform is becoming more popular as networking platform, the Linux data model is changing. Previously ACLs in Linux were highly protocol specific and different utilities were used (iptables, ip6tables, arptables, ebtables), so each one had separate data model. Recently, this has changed and a single utility, nftables, has been developed. With a single application, it has a single data model for firewall filters and it follows very similarly to the ietf-access-control list module proposed in this draft. The nftables support input and output ACEs and each ACE can be defined with match and action.

The example in Section 4.3 can be configured using nftable tool as below.

```
nft add table ip filter
nft add chain filter input
nft add rule ip filter input ip protocol tcp ip saddr \
    10.10.10.1/24 drop
```

The configuration entries added in nftable would be.

```
table ip filter {
    chain input {
        ip protocol tcp ip saddr 10.10.10.1/24 drop
    }
}
```

We can see that there are many similarities between Linux nftables and IETF ACL YANG data models and its extension models. It should be fairly easy to do translation between ACL YANG model described in this draft and Linux nftables.

### A.4. Ethertypes

The ACL module is dependent on the definition of ethertypes. IEEE owns the allocation of those ethertypes. This model is being included here to enable definition of those types till such time that IEEE takes up the task of publication of the model that defines those ethertypes. At that time, this model can be deprecated.

```
<CODE BEGINS> file "ietf-ethertypes@2017-10-03.yang"
```

```
module ietf-ethertypes {
    namespace "urn:ietf:params:xml:ns:yang:ietf-ethertypes";
    prefix ie;
```
