IETF 100th Singapore

An Optional Encoding of the BIFT-id Field in the non-MPLS BIER Encapsulation

draft-wijnandsxu-bier-non-mpls-bift-encoding-00

IJsbrand Wijnands	Cisco	ice@cisco.com
Xiaohu Xu	Huawei	xuxiaohu@huawei.com
Hooman Bidgoli	Nokia	hooman.bidgoli@nokia.com

Background/History

- We have had a long discussion around encapsulation MPLS labels vs Ethernet encoding Decoupling Sub-Domain, Set Identifier, BSL from BIFT-id. Static vs Dynamic BIFT-id's.
- Main goal, have a shared encoding between MPLS and non-MPLS encoding.
- We succeeded in having a shared encapsulation (draftietf-bier-mpls-encapsulation-12)!
- No need to rehash that discussion!

Open issues

- Xiaohu has expressed (from day one) the desire to have static allocated BIFT-id's.
- We have had lively discussions around that topic ^M
- The main reason to avoid static BIFT-id's it to prevent the data-plane from being aware of the BIFT arguments, like Sub-Domain, SI, BSL (others in the future).
- In this draft we're defining a method to create a static BIFT, without the data-plane to be aware.

Static BIFT-id encoding

- The BIFT-id is 20 bits.
- We overload this BIFT-id field and carve out space for: BSL, SD and SI.
- For the data-pane, this remains a 20 bit value!!!
- Data-plane MUST never parse this field.

Static BIFT-id benefits

- No need to advertise BIFT-id to {SD, SI, BSL} mapping.
- The BIFT-id is globally unique. Easier to troubleshoot.

Informational draft

- The reason to document this encoding is to make sure different vendors are interoperable.
- There is no IANA action required.
- This is an informational draft
