

# Secondary Certificates

TLS has a limitation...

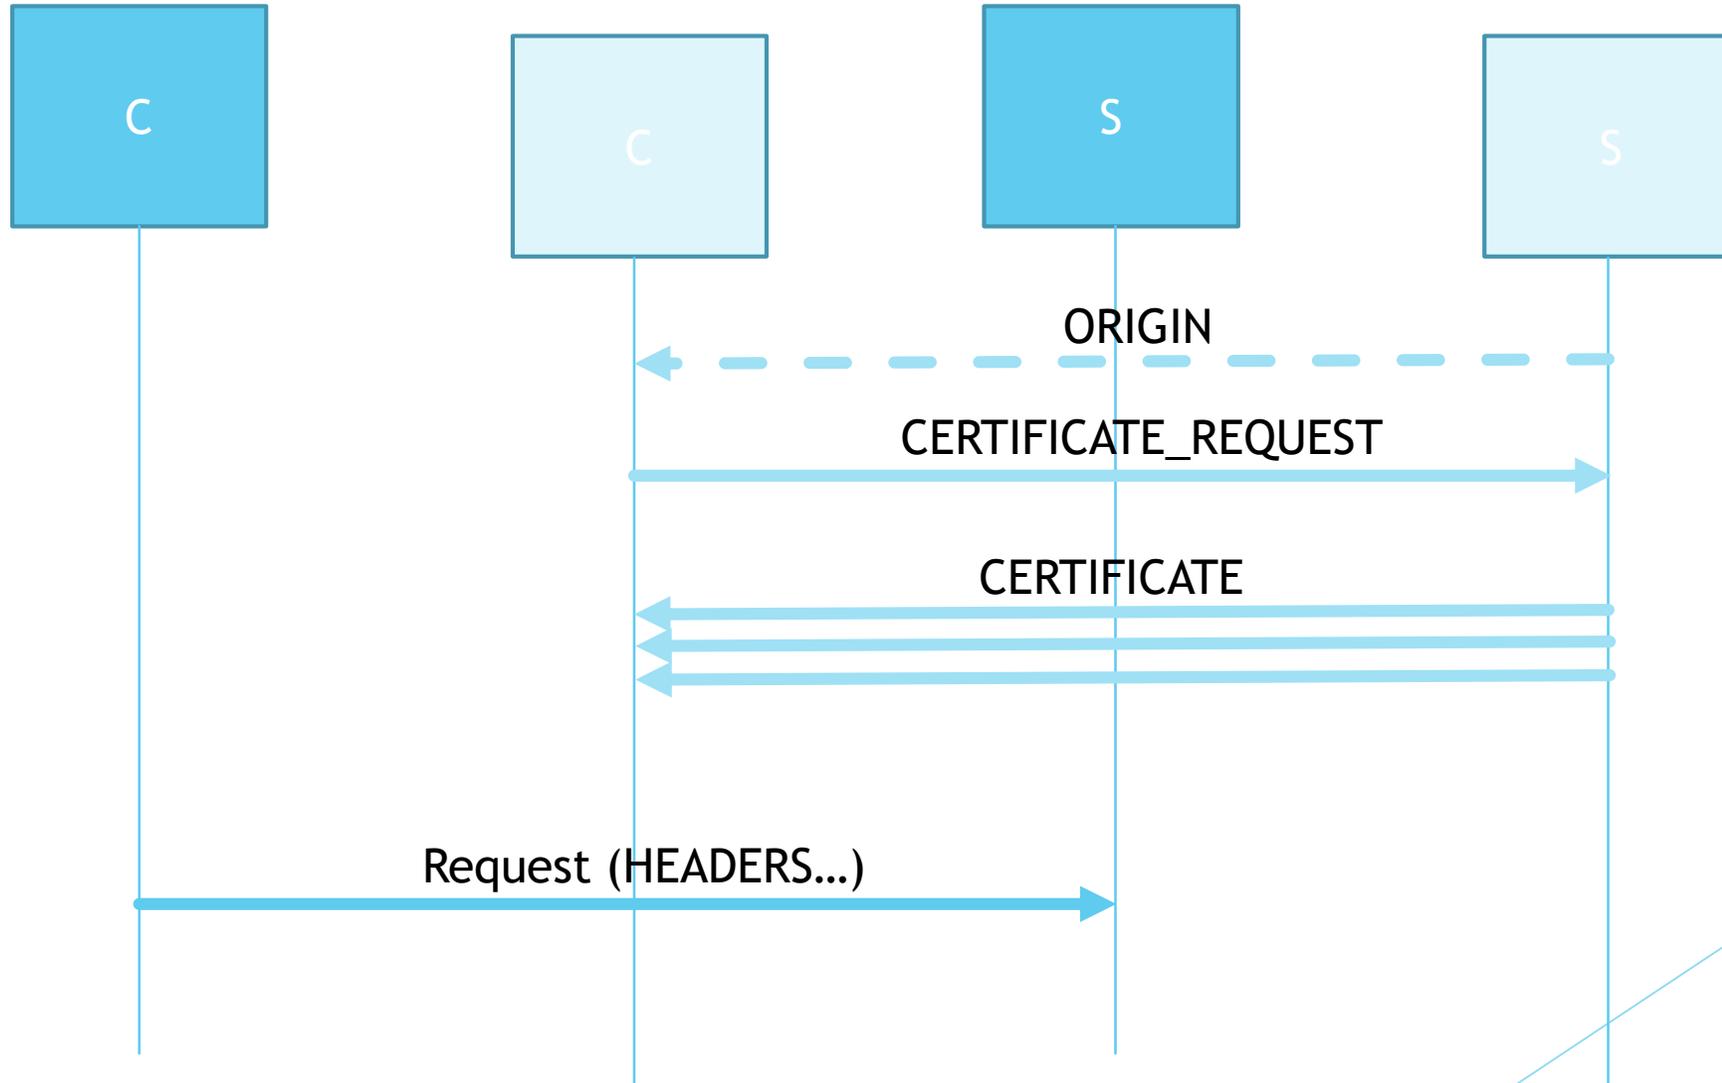

HTTP/2 makes it worse....

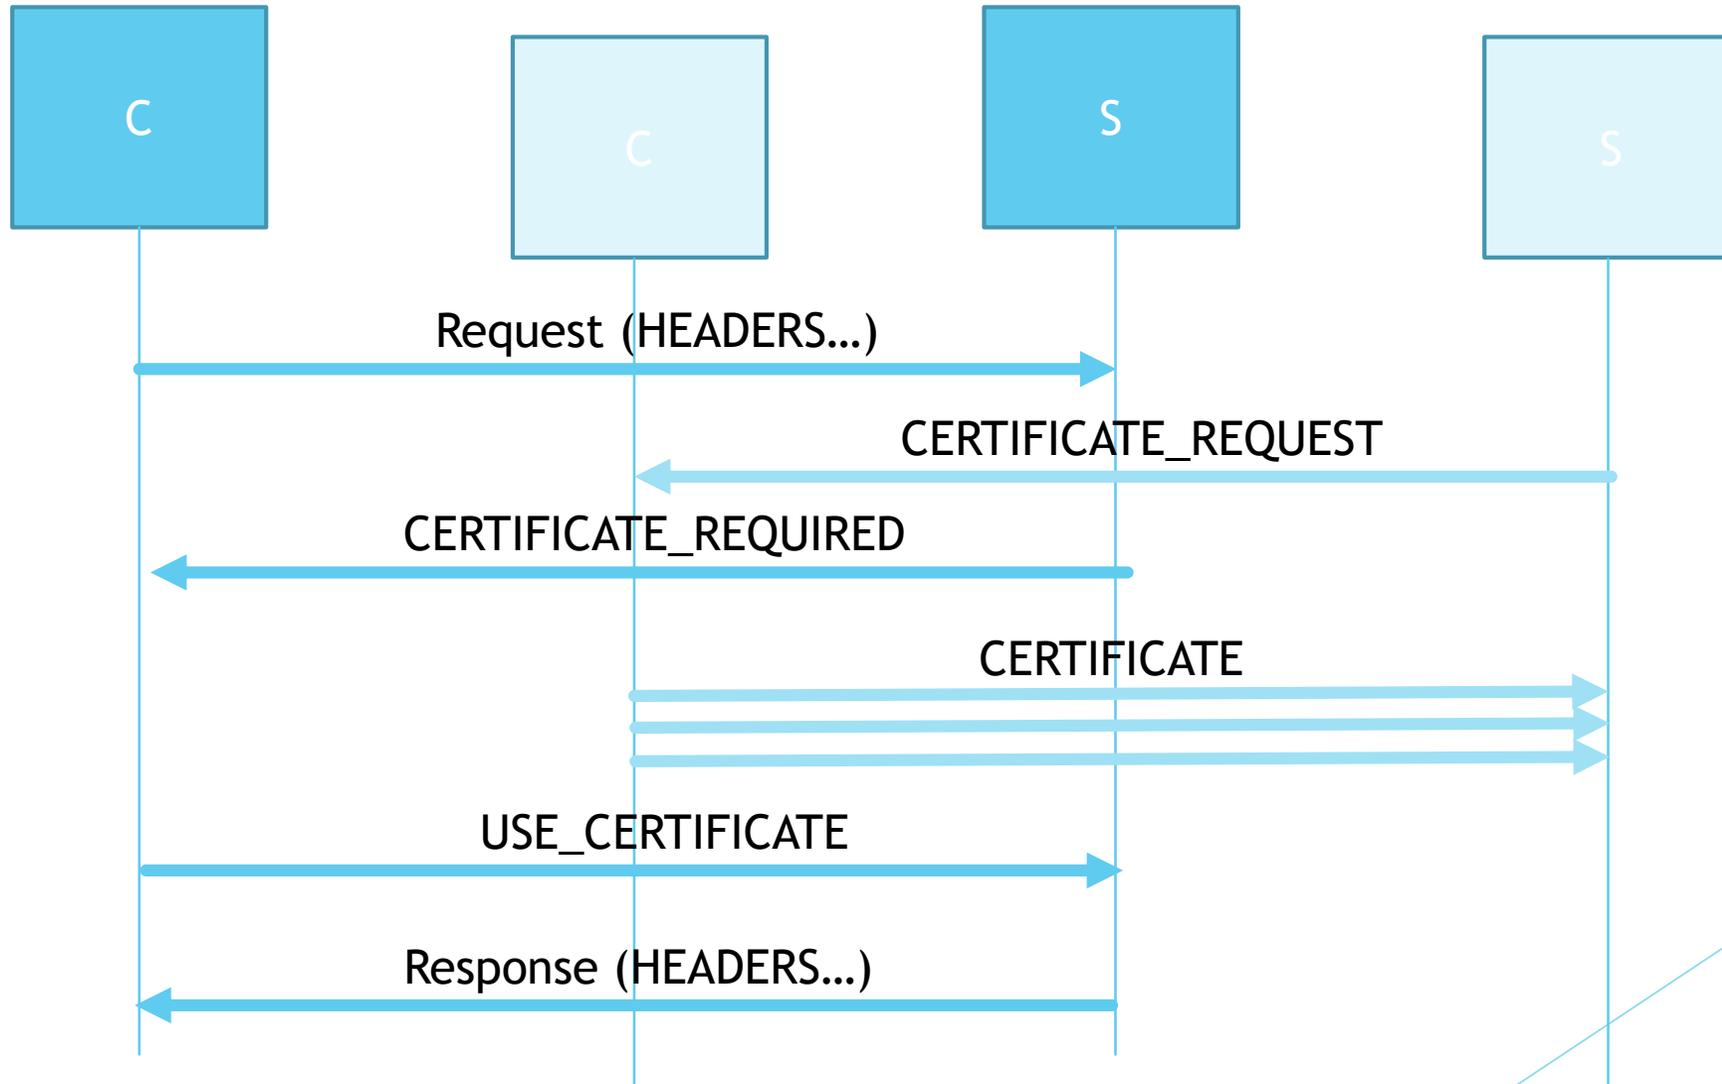

# Recap: Several new frames

- ▶ **CERTIFICATE\_REQUEST (Stream 0)**
  - ▶ Describes a certificate the sender would like to see
  - ▶ Modeled on TLS 1.3 CertificateRequest message
    - ▶ Contains list of Extensions (SNI, OID filters, issuing CAs, etc.)
  - ▶ Probably being replaced with an Exported Authenticator Request
- ▶ **CERTIFICATE\_REQUIRED (Stream N)**
  - ▶ References a CERTIFICATE\_REQUEST, indicates request will not proceed until that request is fulfilled (or a certificate is selected)
- ▶ **CERTIFICATE (Stream 0)**
  - ▶ Contains an Exported Authenticator (draft-ietf-tls-exported-authenticator)
  - ▶ Bound to TLS channel, results in a certificate chain
- ▶ **USE\_CERTIFICATE (Stream N)**
  - ▶ Optionally permits stream-by-stream selection of which certificate to use

# Server Certificates

# Client Certificates

# Possible advantages

- ▶ For servers:
  - ▶ Not everyone has (or wants) a monolithic certificate
  - ▶ Better coalescing
    - ▶ Often good for performance
    - ▶ Single CDN has many authoritative names it serves
  - ▶ Potential option for encrypted SNI
    - ▶ Connect to a well-known name/cert
    - ▶ Include request for “actual” desired certificate after SETTINGS frame
- ▶ For clients:
  - ▶ Client certificates are a real thing
  - ▶ Able to selectively present certificates per request, if you care
    - ▶ ...and ability not to, if you don't

# What's new?

- ▶ Uses TLS Exported Authenticators - no more crypto at the “wrong” layer
  - ▶ Adopted by TLS WG in Chicago
- ▶ Still need to tighten up some of the crypto properties
  - ▶ Likely leads to some changes in the Exported Authenticators draft
- ▶ **Ready for adoption?**
