BFD Stability  
draft-ietf-bfd-stability-12

Abstract

This document describes extensions to the Bidirectional Forwarding Detection (BFD) protocol to measure BFD stability. Specifically, it describes a mechanism for detection of BFD packet loss.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 3 August 2024.

## 1. Introduction

The Bidirectional Forwarding Detection (BFD) [RFC5880] protocol operates by transmitting and receiving BFD control packets, generally at high frequency, over the datapath being monitored. In order to prevent significant data loss due to a datapath failure, BFD session detection time as defined in BFD [RFC5880] is set to the smallest feasible value.

This document proposes a mechanism to detect lost packets in a BFD session in addition to the datapath fault detection mechanisms of BFD. Such a mechanism presents significant value to measure the stability of BFD sessions and provides data to the operators for the cause of a BFD failure.

This document does not propose any BFD extension to measure data traffic loss or delay on a link or tunnel and the scope is limited to BFD packets.

## 2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119] and RFC 8174 [RFC8174].

The reader is expected to be familiar with the BFD [RFC5880], Optimizing BFD Authentication [I-D.ietf-bfd-optimizing-authentication] and BFD Secure Sequence Numbers [I-D.ietf-bfd-secure-sequence-numbers].

## 3. Use Cases

Bidirectional Forwarding Detection as defined in BFD [RFC5880] cannot detect any BFD packet loss if the loss does not last for detection time. This document proposes a method to detect a dropped packet on the receiver. For example, if the receiver receives BFD control packet  $k$  at time  $t$  but receives packet  $k+3$  at time  $t+10\text{ms}$ , and never receives packet  $k+1$  and/or  $k+2$ , then it has experienced a drop.

This proposal enables BFD implementations to generate diagnostic information on the health of each BFD session that could be used to preempt a failure on a datapath that BFD was monitoring by allowing time for a corrective action to be taken.

In a faulty datapath scenario, an operator can use BFD health information to trigger delay and loss measurement OAM protocol (Connectivity Fault Management (CFM) or Loss Measurement (LM)-Delay Measurement (DM)) to further isolate the issue.

## 4. Functionality

The functionality proposed for BFD stability measurement is achieved by configuring the 'stability' flag in the attached YANG model in conjunction with BFD Meticulous Authentication.

## 5. Theory of Operation

This mechanism allows operators to measure the loss of BFD control packets.

When using MD5 or SHA authentication, BFD MUST use an authentication type (bfd.AuthType) that is of type meticulous. Similarly, if BFD uses the OPT bfd.AuthType as defined in Optimizing BFD Authentication [I-D.ietf-bfd-optimizing-authentication], the authentication method it chooses MUST be of type meticulous.

### 5.1. Loss Measurement

Loss measurement counts the number of BFD control packets missed at the receiver during any Detection Time period. The loss is detected by comparing the Sequence Number field in successive BFD control packets. The Sequence Number in each successive control packet generated on a BFD session by the transmitter is incremented by one. This loss count can then be exposed using the YANG module defined in the subsequent section.

The first BFD authentication section with a non-zero sequence number, in a valid BFD control packet, processed by the receiver is used for bootstrapping the logic.

## 6. Stability YANG Module

### 6.1. Data Model Overview

This YANG module augments the "ietf-bfd" module to add a flag 'stability' to enable this feature. The feature statement 'stability' needs to be enabled to indicate that BFD Stability is supported by the implementation. In addition, a loss count per-session or lsp for BFD packets that are lost has also been added in this model.

## 6.2. YANG Module

This YANG module imports Common YANG Types [RFC6991], A YANG Data Model for Routing [RFC8349], and YANG Data Model for Bidirectional Forwarding Detection (BFD) [RFC9314].

```

## 7. IANA Considerations

### 7.1. The "IETF XML" Registry

This document registers one URIs in the "ns" subregistry of the "IETF XML" registry [RFC3688]. Following the format in [RFC3688], the following registration is requested:

URI: urn:ietf:params:xml:ns:yang:ietf-bfd-stability  
Registrant Contact: The IESG  
XML: N/A, the requested URI is an XML namespace.

### 7.2. The "YANG Module Names" Registry

This document registers one YANG modules in the "YANG Module Names" registry [RFC6020]. Following the format in [RFC6020], the following registrations are requested:

name: ietf-bfd-stability  
namespace: urn:ietf:params:xml:ns:yang:ietf-bfd-stability  
prefix: bfds  
reference: RFC XXXX

## 8. Security Consideration

The YANG module specified in this document defines a schema for data that is designed to be accessed via network management protocols such as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF layer is the secure transport layer, and the mandatory-to-implement secure transport is Secure Shell (SSH) [RFC6242]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [RFC8446]. The NETCONF Access Control Model (NACM) [RFC8341] provides the means to restrict access for particular NETCONF or RESTCONF users to a preconfigured subset of all available NETCONF or RESTCONF protocol operations and content.

The YANG module does not define any writeable/creatable/deletable data nodes that can have an adverse impact on a BFD session.

The only readable data nodes in YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes.

The model defines a read-only variables to indicate the number of packets that were lost. Access to this information may allow a malicious user information on which links are experiencing issues.

The YANG module does not define any RPC operations.

## 9. Contributors

The authors of this document would like to acknowledge Jeff Haas as a contributor to this document. Jeff played a role not only as a shepherd but also actively contributed to the improvement of the document. In addition, Manav Bhatia also contributed to this document.

## 10. Acknowledgements

Authors would like to thank Nobo Akiya, Jeffery Haas, Dileep Singh, Basil Saji, Sagar Soni, Albert Fu and Mallik Mudigonda who also contributed to this document.
