YANG Based Instance Data Files Format
draft-lengyel-netmod-yang-instance-data-05

Abstract

There is a need to document data defined in YANG models without the need to fetch it from a live YANG server. Data is often needed already in design time or needed by groups that do not have a live running YANG server available. This document specifies a standard file format for YANG Based Instance data, that is data that could be stored in a datastore and whose syntax and semantics is defined by YANG models. Most important use cases foreseen include documenting server capabilities, factory-default settings, or vendor provided default configurations.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 22, 2019.

1. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 RFC 2119 [RFC2119] RFC 8174 [RFC8174] when, and only when, they appear in all capitals, as shown here.

Design time: A time during which a YANG model and the implementation behind it is created. Sometimes in other documents this period is divided into design and implementation time.

Instance Data Set: A named set of data items that can be used as instance data in a YANG data tree.

Instance Data File: A file containing an instance data set formatted according to the rules described in this document.

Target YANG Module: A YANG module for which the instance data set contains instance data, like ietf-yang-library in the examples.

2. Introduction

There is a need to provide instance data defined in YANG models without the need to fetch it from a live YANG server. Data is often needed already in design time before the YANG server is implemented or needed by groups that do not have a live running YANG server available. To facilitate this off-line delivery of data this document specifies a standard file format for YANG Based Instance data, that is data that could be stored in a datastore and whose syntax and semantics is defined by YANG models.

2.1. Use Cases

We present a number of use cases where Yang based instance data is needed.

2.1.1. Use Case 1: Early Documentation of Server Capabilities

A YANG server has a number of server-capabilities that are defined in YANG modules and can be retrieved from the server using protocols like NETCONF or RESTCONF. YANG server capabilities include

- o data defined in ietf-yang-library: YANG modules, submodules, features, deviations, schema-mounts, datastores supported ([I-D.ietf-netconf-rfc7895bis])
- o alarms supported ([I-D.ietf-ccamp-alarm-module])
- o data nodes, subtrees that support or do not support on-change notifications ([I-D.ietf-netconf-yang-push])
- o netconf-capabilities in ietf-netconf-monitoring

While it is good practice to allow a client to query these capabilities from the live YANG server, that is often not enough.

Often when a network node is released an associated NMS (network management system) is also released with it. The NMS depends on the capabilities of the YANG server. During NMS implementation information about server capabilities is needed. If the information is not available early in some off-line document, but only as instance data from the live network node, the NMS implementation will be delayed, because it has to wait for the network node to be ready. Also assuming that all NMS implementors will have a correctly configured network node available to retrieve data from, is a very expensive proposition. (An NMS may handle dozens of node types.)

Network operators often build their own home-grown NMS systems that needs to be integrated with a vendor's network node. The operator needs to know the network node's server capabilities in order to do this. Moreover the network operator's decision to buy a vendor's product may even be influenced by the network node's OAM feature set documented as the Yang server's capabilities.

Beside NMS implementors, system integrators and many others also need the same information early. Examples could be model driven testing, generating documentation, etc.

Most server-capabilities are relatively stable and change only during upgrade or due to licensing or addition or removal of HW. They are usually defined by a vendor in design time, before the product is released. It is feasible and advantageous to define/document them early e.g. in a Yang Based Instance Data File.

It is anticipated that a separate IETF document will define in detail how and which set of server capabilities should be documented.

2.1.2. Use Case 2: Preloading Data

There are parts of the configuration that must be fully configurable by the operator, however for which often a simple default configuration will be sufficient.

One example is access control groups/roles and related rules. While a sophisticated operator may define dozens of different groups often a basic (read-only operator, read-write system administrator, security-administrator) triplet will be enough. Vendors will often provide such default configuration data to make device configuration easier for an operator.

Defining Access control data is a complex task. To help the device vendor pre-defines a set of default groups (/nacm:nacm/groups) and rules for these groups to access specific parts of common models (/nacm:nacm/rule-list/rule).

YANG Based Instance data files are used to document and/or preload the default configuration.

2.1.3. Use Case 3: Documenting Factory Default Settings

Nearly every YANG server has a factory default configuration. If the system is really badly misconfigured or if the current configuration is to be abandoned the system can be reset to this default.

In Netconf the <delete-config> operation can already be used to do this for the startup configuration. There are ongoing efforts to introduce a new, more generic reset operation for the same purpose [I-D.wu-netconf-restconf-factory-restore]

The operator currently has no way to know what the default configuration actually contains. YANG Based Instance data can be used to document the factory default configuration.

3. Instance Data File Format

Two standard formats to represent YANG Based Instance Data are specified based on the XML and JSON encoding. The XML format is based on [RFC7950] while the JSON format is based on [RFC7951]. Later as other YANG encodings (e.g. CBOR) are defined further Instance Data formats may be specified.

For both formats data is placed in a top level auxiliary container named "instance-data-set". The purpose of the container, which is not part of the real data itself, is to carry meta-data for the complete instance-data-set.

The XML format SHALL follow the format returned for a NETCONF GET operation. The <data> anydata (which is not part of the real data itself) SHALL contain all data that would be inside the <data> wrapper element of a reply to the <get> operation. XML attributes SHOULD NOT be present, however if a SW receiving a YANG Based Instance data file encounters XML attributes unknown to it, it MUST ignore them, allowing them to be used later for other purposes.

The JSON format SHALL follow the format of the reply returned for a RESTCONF GET request directed at the datastore resource: {+restconf}/data. ETags and Timestamps SHOULD NOT be included, but if present SHOULD be ignored.

A YANG Based Instance data file MUST contain a single instance data set. Instance data MUST conform to the corresponding target YANG Modules and follow the XML/JSON encoding rules as defined in [RFC7950] and [RFC7951] and use UTF-8 character encoding. A single instance data set MAY contain data for any number of target YANG modules, if needed it MAY carry the complete configuration and state data set for a YANG server. Default values SHOULD NOT but MAY be included. Config=true and config=false data MAY be mixed in the instance data file. Instance data files MAY contain partial data sets. This means mandatory, min-elements or require-instance=true constraints MAY be violated.

The name of the file SHOULD be of the form:

```
instance-data-set-name ['@' revision-date] ( '.yid' )
```

E.g. acme-router-modules@2018-01-25.yid

The revision date is optional. It SHOULD NOT be used if the file is stored in a version control system (e.g. git) because the change of file names will break the connection between the different revisions of the file.

Meta data, information about the data set itself SHALL be included in the instance data set. This data will be children of the top level instance-data-set container as defined in the ietf-instance-data YANG module. Meta data SHALL include:

- o Name of the instance data set

Meta data SHOULD include:

- o Revision date of the instance data set
- o Description of the instance data set. The description SHOULD contain information whether and how the data can change during the lifetime of the YANG server.

```
<?xml version="1.0" encoding="UTF-8"?>

4. Data Life cycle

Data defined or documented in YANG Based Instance Data Sets may be used for preloading a YANG server with this data, but the server may populate the data without using the actual file in which case the Instance Data File is only used as documentation.

While such data will usually not change, data documented by Instance Data sets MAY be changed by the YANG server itself or by management operations. It is out of scope for this document to specify a method to prevent this. Whether such data changes and if so, when and how, SHOULD be described either in the instance data file description statement or in some other implementation specific manner.

YANG Based Instance data is a snap-shot of information at a specific point of time. If the data changes afterwards this is not represented in the instance data set anymore, the valid values can be retrieved in run-time via Netconf/Restconf

Notifications about the change of data documented by Instance Data Sets may be supplied by e.g. the Yang-Push mechanism, but it is out of scope for this document.

5. Delivery of Instance Data

Instance data files SHOULD be available without the need for a live YANG server e.g. via download from the vendor's website, or any other way together with other product documentation.

6. YANG Model

```
<CODE BEGINS> file "ietf-yang-instance-data.yang"

module ietf-yang-instance-data {
  yang-version 1.1;
  namespace
    "urn:ietf:params:xml:ns:yang:ietf-yang-instance-data";

    description "Initial revision.";
    reference "RFC XXXX: YANG Based Instance Data";
  }

  yd:yang-data instance-data-format {
    container instance-data-set {
      description "Auxiliary container to carry meta-data for
        the complete instance data set.";

      leaf name {
        type string;
        mandatory true;
      }
    }
  }
}
```

```
    description "Name of a YANG Based Instance data set.";
  }

  leaf description { type string; }

  leaf contact {
    type string;
    description "Contains the same information the contact
      statement carries for a YANG module.";
  }

  leaf organization {
    type string;
    description "Contains the same information the
      organization statement carries for a YANG module.";
  }

  leaf datastore {
    type ds:datastore-ref;
    description "The identity of the datastore for which
      the instance data is documented for config=true data nodes.
      The leaf MAY be absent in which case the running dtastore or
      if thats not writable, the candidate datastore is implied.

      For config=false data nodes always the operational
      data store is implied.";
  }

  list revision {
    key date;
    description "An instance-data-set SHOULD have at least
      one revision entry. For every published
      editorial change, a new one SHOULD be added in front
      of the revisions sequence so that all revisions are
      in reverse chronological order.";

    leaf date {
      type string {
        pattern '\d{4}-\d{2}-\d{2}';
      }
      description "Specifies the data the revision
        was last modified. Formated as YYYY-MM-DD";
    }

    leaf description { type string; }
  }

  anydata data {
```

```
        mandatory true;
        description "Contains the real instance data.
            The data MUST conform to the relevant YANG Modules.";
    }
}
}
}
```

<CODE ENDS>

7. Security Considerations

Depending on the nature of the instance data, instance data files MAY need to be handled in a secure way. The same type of handling should be applied, that would be needed for the result of a <get> operation returning the same data.

8. IANA Considerations

To be completed, all the usual requests for a new YANG module

Appendix A. Open Issues

- o If we define metadata per target module, a list of target YAM could be included in the metadata. This depends on what additional metadata we will include.
- o How do we know for which version of the target Yang Module is a data set valid? Proposal: One possibility would be to just indicate for which module version(s) was the data set last updated. This would be a hint about compatibility, but nothing more. Maybe we should wait till the YANG versioning work is complete/stable. Identifying just one version is way to strict, so something enforcing that shall not be used.
- o Should we document what YANG features does the instance data set implicitly require? Proposal: that is already a use case, documenting data from the YANG library.
- o Augmenting metadata must be possible. As of now it looks like yang-data-ext will solve that. If not, define instance data as regular YANG instead of yd:yang-data.

Appendix B. Changes between revisions

v04 - v05

- o Changed title and introduction to clarify that this draft is only about the file format and documenting server capabilities is just a use case.
- o Added reference to draft-wu-netconf-restconf-factory-restore
- o Added new open issues.

v03 - v04

- o Updated changelog for v02-v03

v02 - v03

- o Updated the document according to comments received at IETF102
- o Added parameter to specify datastore
- o Rearranged chapters
- o Added new use case: Documenting Factory Default Settings
- o Added "Target YANG Module" to terminology
- o Clarified that instance data is a snapshot valid at the time of creation, so it does not contain any later changes.
- o Removed topics from Open Issues according to comments received at IETF102

v01 - v02

- o The recommendation to document server capabilities was changed to be just the primary use-case. (Merged chapter 4 into the use case chapter.)
- o Stated that RFC7950/7951 encoding must be followed which also defines (dis)allowed whitespace rules.
- o Added UTF-8 encoding as it is not specified in t950 for instance data
- o added XML declaration

v00 - v01

- o Redefined using yang-data-ext
- o Moved meta data into ordinary leafs/leaf-lists
