               PCEP Extension for Stateful Inter-Domain Tunnels
                  draft-dugeon-pce-stateful-interdomain-02

   Abstract

      This document proposes to combine a Backward Recursive or
      Hierarchical method in Stateful PCE with PCInitiate message to setup
      independent paths per domain, and combine these different paths
      together in order to operate them as end-to-end inter-domain paths
      without the need of signaling session between AS border routers. A
      new Stitching Label is defined, new Path Setup Types and a new
      Association Type are considered for that purpose.

   Requirements Language

      The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
      "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this
      document are to be interpreted as described in RFC 2119 [RFC2119].

Table of Contents

1. Introduction

   The Path Computation Element (PCE) working group (WG) has produced a
   set of RFCs to standardize the behavior of the Path Computation
   Element as a tool to help MPLS-TE, GMPLS LSP tunnels and Segment
   Routing paths placement. This also includes the ability to compute
   inter-domain LSPs or Segment Routing paths following a distributed or
   hierarchical approach. To complement the original stateless mode, a
   stateful mode has been added. In particular, the new PCInitiate
   message allows a PCE to directly ask a PCC to setup an MPLS-TE, GMPLS
   LSP tunnel or a Segment Routing path. However, once computed, the
   inter-domain LSPs or Segment Routing path are hard to setup in the
   underlying network. Especially, in operational network, RSVP-TE
   signaling is not enabled between AS border routers. But, such RSVP-
   TE signaling is mandatory to setup contiguous LSP tunnels or to
   stitch or nest independent LSP tunnels to form the end-to-end inter-
   domain paths.

   Looking to the different RFCs that describe the PCE architecture and
   in particular PCE based architecture [RFC4655], PCE protocol
   [RFC5440], BRPC [RFC5441] and H-PCE [RFC6805], the Path Computation
   Element (PCE) is able to compute inter-domain paths in complement to
   intra-domain computation. Such inter-domain paths could then serve
   as the Explicit Route Object input for the RSVP-TE signaling to setup
   the tunnels within the underlying network. Three kinds of inter-
   domain paths could be established:

   o Contiguous tunnel ([RFC3209] and [RFC3473]): The RSVP-TE signaling
      crosses the boundary between two domains, e.g. between two AS
      Border Routers (ASBRs) as if they were two routers of the same
      domain. This kind of tunnel is not recommended mostly for
      security and scalability purpose. In addition, the initiating
      domain imposes huge constraints on subsequent domains, because
      they undergo the tunnel request without being able to control it.

   o Stitching tunnel ([RFC5150]): Each domain establishes in its own
      network the corresponding part of the inter-domain path
      independently. Then, a second end-to-end RSVP-TE Path message is
      sent by the initiating domain to stitch the different tunnel parts
      to form the inter-domain path. In fact, this second RSVP-TE Path
      message is used by border nodes to exchange the label that must be
      used by the previous domain to send the traffic in order that the

MPLS packets follow the next LSP tunnel in the following domain. These labels are conveyed in the RSVP-TE Resv message.

o Nesting tunnel ([RFC4206]): This is similar to the stitching mode but, this time, with the possibility to setup tunnel hierarchy. For example, an LSP tunnel between two edge domains crossing a transit domain could be carried over a tunnel of a higher level in the transit domain. Again, a second end-to-end RSVP-TE Path message is sent from the source to the destination. Labels that must be used by the ASBRs of transit domains to identify flows to be nested are carried by the RSVP-TE Resv message.

In all case, RSVP-TE signaling must be exchanged between the different domains. However, from an operational point of view, looking to different networks under the responsibility of different administrative entities, only BGP sessions are setup and configured between ASBRs. Technologically speaking, this is possible and many RFCs describe how to use RSVP-TE for inter-domain. But, due to security, scalability, management and contract constraints, RSVP-TE is not exposed at the network boundary. To circumvent some of the security issues, RSVP-TE can be carried inside an IPsec tunnel between ASBRs, but, this does not eliminate the scalability aspect nor the constraints imposed by setting up inter-domain paths.

The purpose of this memo is to take the benefit of PCE Stateful [RFC8231] and PCE Initiated [RFC8281] modes to stitch or nest inter-domain paths directly using PCEP between domains' PCEs instead of using RSVP-TE signaling at the inter-domain border nodes, while keeping each operator free to independently setup their respective part of the inter-domain paths. PCInitiate message is used in a Backward Recursive way like the PCReq message in BRPC [RFC5441], to recursively setup the end-to-end tunnel. PCRep message is used to automatically stitch or nest the different local LSP tunnels. And, PCRep in conjunction of PCUpd messages are used to maintain, modify and remove inter-domain paths. This method is also applicable to Segment Routing to build inter-domain segment paths.

H-PCE [RFC6805] describes a Hierarchical PCE architecture which can be used for computing end-to-end paths for inter-domain MPLS Traffic Engineering (TE) and GMPLS Label Switched Paths (LSPs). Within this architecture, the Parent PCE (P-PCE) is used to compute a multi-domain path based on the domain connectivity information. A Child PCE (C-PCE) may be responsible for a single domain or multiple domains, it is used to compute the intra-domain path based on its domain topology information.

Stateful H-PCE [I-D.ietf-pce-stateful-hpce] presents general considerations for stateful PCE(s) in hierarchical PCE architecture.

In particular, the behavior changes and additions to the existing
stateful PCE mechanisms (including PCE-initiated LSP setup and active
PCE usage) in the context of networks using the H-PCE architecture.
Section 3.3.1 [I-D.ietf-pce-stateful-hpce] describes the per domain
stitched LSP mode, where the individual per domain LSP are stitched
together. PCInitiate message is also used to stitch the end-to-end
tunnel. See section 4 for details.

1.1. General assumptions

In the rest of this document, we used the same references as per BRPC
[RFC5441] and make the following set of assumptions (see figure
below):

o Domain refers to an IGP area or an Autonomous System (AS).

o Inter-domain path is used to refer to a path that cross two or
   more different domains as defined previously,

o At least, one PCE is deployed in each domain. These PCE are all
   stateful active capable and could request to enforce LSP tunnels
   in their respective domain by means of PCInitiate messages.

o LSRs, including border nodes, are PCC enable and support stateful
   active mode. PCEP sessions is established between these routers
   and their domains' PCE.

o Each PCE establishes a PCEP session with its respective neighbor
   domain's PCE. The way a PCE discover its neighboring PCE is out
   of scope of this draft. These information could be fulfill
   administratively or automatically discovered through, for example
   per draft 'BGP Extensions for Path Computation Element (PCE)
   Discovery' [I-D.dong-pce-discovery-proto-bgp].

o PCEs are able to compute and end-o-end path as per BRPC procedure
   [RFC5441] or as per H-PCE procedure (stateless [RFC6805] or
   stateful [I-D.ietf-pce-stateful-hpce]).

o Tunnels refer to LSPs setup by mean of RSVP-TE or Segment Path in
   a Segment Routing network.

           Example of the representation of 3 domains with 3 PCEs

1.2. Terminology

   ABR: Area Border Routers. Routers used to connect two IGP areas
   (areas in OSPF or levels in IS-IS).

   AS: Autonomous System

   ASBR: Autonomous System Border Router. Router used to connect
   together ASes of the same or different service providers via one or
   more inter-AS links.

   Border Node (BN): a boundary node is either an ABR in the context of
   inter-area Traffic Engineering or an ASBR in the context of inter-AS
   Traffic Engineering.

   BN-en(i): Entry BN of domain(i) connecting domain(i-1) to domain(i)
   along a determined sequence of domains. Multiple entry BN-en(i)
   could be used to connect domain(i-1) to domain(i).

   BN-ex(i): Exit BN of domain(i) connecting domain(i) to domain(i+1)
   along a determined sequence of domains. Multiple exit BN-ex(i) could
   be used to connect domain(i) to domain(i+1).

Domains: Autonomous System (AS) or IGP Area. An Autonomous System is composed by one or more IGP area.

ERO(i): The Explicit Route Object scoped to domain(i)

IGP-TE: Interior Gateway Protocol with Traffic Engineering support. Both OSPF-TE and IS-IS-TE are identified in this category.

Inter-domain path: A path that crosses two or more domains through a pair of Border Node (BN-ex, BN-en).

LK(i): A Link that connect BN-ex(i-1) to BN-en(i). Note that BN-ex(i-1) could be connected to BN-en(i) by more than one link. LK(i) serves to identify which of the multiple links will be used for the inter-domain LSP setup.

Local LSP tunnel: A LSP tunnel that do not cross a domain. It is setup between entry BN-en to output BN-ex, any source to output BN-ex or entry BN-en to any destination of the same domain. This LSP could be enforce by means of RSVP-TE signaling or Segment Routing labels stack.

Local LSP tunnel(i): A local LSP tunnel of domain(i)

PLSP-ID(i): A PLSP-ID that identify the local tunnel part of an inter-domain tunnel in the domain(i).

PCE: Path Computation Element. An entity (component, application, or network node) that is capable of computing a network path or route based on a network graph and applying computational constraints.

PCE(i) is a PCE with the scope of domain(i).

PST: Path Setup Type

R(i,j): The router j of domain i

Stitching Label (SL): A dedicated label that is used to stitch two RSVP-TE tunnels or two Segment Routing paths.

SL(i): A Stitching Label that link domain(i-1) to domain(i).

2. Stitching Label

This section introduce the concept of Stitching Label that allows stitching and nesting of local LSP tunnels in order to form inter-domain path that cross several different domains.

2.1. Definition

   The operation of stitch or nest a local LSP tunnel(i) to a local LSP
   tunnel(i+1) in order to form and inter-domain path simply consist in
   defining the label that the output BN-ex(i) will use to send its
   traffic to the entry BN-en(i+1). Indeed, the entry BN-en(i+1) needs
   to identify the incoming traffic i.e. IP packets, in order to know if
   this traffic must follow the local LSP tunnel(i+1) or not.
   Forwarding Equivalent Class (FEC) could be used for that purpose.
   But, when stitching or nesting tunnels, the FEC is reduce to the
   incoming label that the entry BN-en(i+1) as chosen for the local LSP
   tunnel(i+1).

   In this memo, we introduce the named of 'Stitching Label (SL)' to
   designate this label. Such label is usually exchange between output
   BN-ex(i) and entry BN-en(i+1) with the RSVP-TE signaling. But, as we
   want to avoid to use RSVP-TE signaling due to operational
   constraints, this Stitching Label will be convey by PCEP protocol.
   In fact, the Explicit Route Object (ERO) and the Record Route Object
   (RRO) are defined in order to transport this Stitching Label in the
   RSVP-TE signaling. As PCEP protocol used RSVP-TE Objects, and in
   particular the ERO and RRO, it is able to convey the Stitching Label
   without any modification of the PCEP protocol nor the PCE or RSVP-TE
   Objects.

   As per RFC4003 [RFC4003], the Stitching Label will be convey as a
   companion of an IP address. In our case, this is one of the IP
   address of the link LK(i) which connects BN-ex(i) to BN-en(i+1) and
   carries the traffic from the domain(i) to domain(i+1). It is left to
   implementation to select which of the two IP address of the link
   LK(i) is used.

2.2. Inter-domain LSP-TYPE

   However, even if PCEP could convey the Stitching Label, a PCC is not
   aware that a PCE requests or provides such label. For that purpose,
   this memo propose to use the PST as defined in [RFC8408] with new
   values (See IANA section of this memo) defined as follow:

   o TBD1: Inter-Domain Traffic engineering end-to-end path is setup
      using Backward Recursive or Hierarchical method. This new PST
      value MUST be set in a PCInitiate messages sends by a PCE(i) to
      its neighbor PCE(i+1) in the Backward Recursive method or by the
      Parent PCE to the Child PCE(i) to initiate a new inter-domain
      path. In turn, neighbor PCE(i+1) or Child PCE(i) MUST return a
      Stitching Label SL with the IP address of the associated link in
      the RRO of the PCRpt message to PCE(i) or Parent PCE.

   o TBD2: Inter-Domain Traffic engineering local path is setup using
      RSVP-TE. This new PST value MUST be set in the PCInitiate message
      sends by a PCE(i) requesting to a PCC of domain(i) to initiate a
      new local LSP tunnel(i) which is part of an inter-domain path.
      This PST value MUST be used by the PCE(i) only after receiving a
      PCInitiate message with an PST equal to TBD1 from a neighbor
      PCE(i+1) in the Backward Recursive method or Parent PCE in the
      Hierarchical method. In turn, the PCC of domain(i) MUST return a
      Stitching Label SL with the IP address of associated link in the
      RRO of the PCRpt message.

   o TBD3: Inter-Domain Traffic engineering local path is setup using
      Segment Routing. This new PST value MUST be set in the PCInitiate
      message sends by a PCE(i) requesting to a PCC of domain(i) to
      initiate a new Segment Routing path which is part of and inter-
      domain Segment Routing path. This PST value MUST be used by the
      PCE(i) only after receiving a PCInitiate message with an PST equal
      to TBD1 from a neighbor PCE(i+1). In turn, the PCC MUST return a
      Stitching Label SL with the IP address of the associated link in
      the RRO of the PCRpt message.

3. Backward Recursive PCInitiate procedure

   This section describes how to setup inter-domain paths than cross
   several different domains by using a Backward Recursive method which
   is compatible to inter-domain path computation by means of the BRPC
   procedure as describe in RFC5441 [RFC5441].

3.1. Mode of operation

   This section describes how PCInitiate and PCRpt messages are combined
   between PCE in order to setup inter-domain paths between a source
   domain(1) to a destination domain(n). S and D are respectively the
   source and destination of the inter-domain path. Domain(1) and
   domain(n) are different and connected through 0 or more intermediate
   domains denoted domain(i) with i = (2, n-1). Domains are directly
   connected when n = 2.

   First, the PCE(1) runs standard BRPC algorithm as per RFC5441
   [RFC5441] with its neighbor PCEs in order to compute the inter-domain
   path from S to D, where S and D are respectively a node in the
   domain(1) and domain(n). Path Key confidentiality as per RFC5520
   [RFC5520] SHOULD be used to obfuscate the detailed ERO(i) of the
   different domains(i). The resulting ERO is of the form {S, PKS(1),
   BN-ex(1), ..., BN-en(i), PKS(i), BN-ex(i), ..., BN-en(n), PKS(n), D}
   when Path Key is used and of the form {S, R(1,1), ..., R(1,k), BN-
   ex(1), ..., BN-en(i), R(i,1), ..., R(i,l), BN-ex(i), ..., BN-en(n),
   R(n,1), ..., R(n,m), D} otherwise . As subsequent domains are not

aware about the final computed ERO in case of multiple VSPTs, the
final ERO selected by the PCE(1) MUST be sent in the PCInitiate
message to indicate to the subsequent PCEs which solution has been
finally chosen. PCE(1) MUST ensure that this ERO is self
comprehensive by subsequent PCEs. Indeed, when a PCE(i) receives the
ERO, it MUST be able to verify that it is in the scope of this ERO
and to determine the PCE(i+1). When Path Key is used, PCEs MUST
encode the Path Key with a reachable IP address in order for previous
PCEs in the AS chain to join them. When Path Key is not used, the
PCEs MUST be able to retrieve IP address of the next PCE from the
ERO.

The complete procedure with Path Key follow the different steps
described below:

Steps 1: Initialization

Once ERO(S, D) is computed, PCE(1) sends a PCInitiate message to
PCE(2) containing an ERO equal to {S, PKS(2), ..., PKS(i), ...,
PKS(n), D}, PST = TBD1 and End-Points Object = (S, D). The ERO
corresponds to the one PCE(1) has received from PCE(2) during the
BRPC process in which only Path Key are kept. In case of multiple
EROs, i.e. VSPT, PCE(1) has chosen one of them and used the selected
one for the PCInitiate message. PKS(i) could be replaced by the full
ERO description if Path Key is not used by PCE(i).

When PCE(i) receives a PCInitiate message from domain(i-1) with PST =
TBD1 and ERO = {PKS(i), PKS(i+1), ..., PKS(n), D)}, it sends a
PCInitiate message to PCE(i+1) with a popped ERO and records its
received PKS(i) part. All PCE(i)s generate the appropriate
PCInitiate message to PCE(i+1) up to PCE(n), i.e. to the destination
domain(n).

Steps 2: Actions taken at the destination domain(n) by PCE(n)

When PCInitiate message propagation reach the destination domain(n),
PCE(n) retrieves the ERO from the PKS(n) if necessary and sends to
BN-en(n) a PCInitiate message with the ERO(n) = {BN-en(n), ..., D},
PST = TBD2 and End-Points Object = {BN(n), D} in order to inform the
PCC BN-en(n) that this local LSP tunnel(n) is part of an inter-domain
path. When the PCC BN-en(n) received the PCInitiate message from its
PCE(n), it setup the local LSP tunnels from entry BN-en(n) to D by
means of RSVP-TE signaling with the given ERO(n). Once the tunnel
setup, it chooses a free label for the Stitching Label SL(n) and add
a new entry in its MPLS L(F)IB with this SL(n) label. Then, it sends
a PCRpt message to its PCE(n) with an RRO equal to {[LK(n), SL(n)],
RRO(n)} and PLSP-ID(n). Once PCE(n) receives the PCRpt from the PCC
BN-en(n) with the RRO, PLSP-ID and PST = TBD2, it sends to the

PCE(n-1) a PCRpt containing the RRO equal to {[LK(n), SL(n)]} and
PLSP-ID(n). PCE(n) MAY add {PKS(n), D} in the RRO.

Steps i: Actions performed by all intermediate domains(i), for i = 2
to n-1

1. When the PCE(i) receives a PCRpt message from domain(i+1) with
    PST = TBD1, RRO = {[LK(i+1), SL(i+1)]} and PLSP-ID(i+1), it
    retrieves the ERO(i) from the PKS(i), recorded in step 1, and
    sends to the PCC BN-en(i) a PCInitiate message with ERO =
    {ERO(i), [LK(i+1), SL(i+1)]}, PST = TBD2 and End-Points Object =
    {BN-en(i), BN-ex(i)} in order to inform the PCC BN-en(i) that
    this local LSP tunnel(i) is part of an inter-domain path.

2. When the PCC BN-en(i) received the PCInitiate message from its
    PCE(i), it setup the local LSP tunnels from BN-en(i) to BN-ex(i)
    by means of RSVP-TE signaling with the given ERO(i).

3. Egress Control mechanism, as per RFC4003 section 2.1 [RFC4003],
    is used to instruct the egress node of domain(i), i.e. BN-ex(i),
    to forward packets belonging to this tunnel with the Stitching
    Label. Both Stitching Label and IP address of outgoing interface
    are carried in the ERO = {..., [LK(i+1), SL(i+1)]} as the last
    SubObject in conformance to [RFC4003]. So that, BN-ex(i)
    installs in its MPLS L(F)IB the SWAP instruction to label SL(i+1)
    with forward to LK(i+1).

4. Once the tunnel setup, PCC BN-en(i) chooses a free label for the
    Stitching Label SL(i) and adds a new entry in its MPLS L(F)IB
    with this SL(i) label. Then, it sends a PCRpt message to its
    PCE(i) with an RRO equal to {[LK(i), SL(i)], RRO(i)} and PLSP-
    ID(i).

5. Once PCE(i) receives the PCRpt from the PCC BN-en(i) with the RRO
    and PST = TBD2, it sends to the PCE(i-1) a PCRpt message
    containing the RRO equal to {[LK(i), SL(i)]} and the PLSP-ID(i).
    PCE(i) MAY add {PKS(i), ..., PKS(n)} in the RRO.

Steps n: Actions performed at the source domain(1) by PCE(1)

Once PCE(1) received the PCRpt message from PCE(2) with the RRO
containing the label SL(2), it sends a PCInitiate message to PCC node
S with ERO equal to {ERO(1), [LK(2), SL(2)]}, PST = 0 and End-Points
Object = {S, BN-ex(1)}. This time, the PST is equal to 0 as the PCC S
does not need to return a Stitching Label SL, i.e. it is the head-end
of the inter-domain path. Standard PCRpt message is sent back to
PCE(1) by the PCC node S.

3.2. Example

   In the figure below, two different domains S and D are interconnected
   through BN respectively BN-S and BN-D. PE-S and PE-D are edge
   routers. All routers in the figure are connected to their respective
   PCE through PCEP protocol. In this example, PCE(S) would setup an
   inter-domain path between PE-S and PE-D acting as source and
   destination of the tunnel. Intermediate routers between (PE-S, BN-
   S), (BN-D and PE-D) as well as RSVP-TE messages are not represented
   to simplify the figure. But they are all presents. The following
   notation is used in the figure (note that, in this example, we use
   the PKS for the sake of simplicity):

   o PKS(D) = Path Key corresponding to the path from BN(D) to PE-D

   o ERO(D) = Explicit Route Object corresponding to the path from
      BN(D) to PE-D retrieves from PKS(D)

   o RRO(D) = Record Route Object of local LSP tunnel(D) from BN(D) to
      PE-D

   o SL(D) = Stitching Label for local LSP tunnel from BN(D) to PE-D

   o ERO(S) = Explicit Route Object corresponding to the path from PE-S
      to BN(S)

   o RRO(S) = Record Route Object of local LSP tunnel(S) from PE-S to
      BN(S)

```
     PE-S        PCE-S                           BN-D      PCE-D
      |           |                                |         |
      |           [ -------- Standard BRPC exchange ------------]
      |           |                                |         |
      |           |    PCInitiate(ERO={PKS(D)}, PST = TBD1)   |

```
        Example of inter-domain path setup between two domains

3.3. Inter-domain LSP setup procedure completion failure

   In case of error during LSP setup, PCRpt and or PCErr messages MUST
   be used to signal the problem to the neighbor PCE domain backward.
   In particular, if new PST values defined in this memo are not

supported by the neighbor PCE or the PCC, the PCE, receptively the
PCC, MUST return a PCErr message with Error-Type = 21 (Traffic
engineering path setup error) and Error-Value = 1 (Unsupported path
setup type) to its neighbor PCE. If a PCE(i) receives a PCInitiate
message from its peer PCE(i-1) without PST set to TBD1 or PST set to
a value different from TBD1, it MUST return a PCErr message with
Error-Type = 21 (Traffic engineering path setup error) and Error-
Value = 1 (Unsupported path setup type) to its peer PCE(i-1).

If a PCC or a PCE don't return an RRO or an RRO without the Stitching
Label SL with the IP address of the associated link following a
PCInitiate message with PST set to TBD1, the PCE MUST return a PCErr
message with Error-Type = 21 (Traffic engineering path setup error)
and Error-Value = TBD5 (No Mandatory Stitching Label is present in
the RRO).

In case of completion failure, the PCE(i) MUST propagate the PCErr
message up to the PCE(1). In turn, PCE(1) MUST send a PCInitiate
message (R flag set in the SRP Object as per draft pce initiated lsp
[RFC8281]) to delete this inter-domain path to its neighbor PCEs.
PCE(i) MUST propagate the PCInitiate message and remove their local
LSP tunnel by means of PCInitiate message to their PCC BN-en(i) and
send back PCRpt message to PCE(i-1).

In case of error in domain(i+1), PCE(i) MAY add the AS number of
domain(i+1) in the RRO to identify the faulty domain.

4. Hierarchical PCInitiate procedure

   This section describes how to setup inter-domain paths than cross
   several different domains by using a Hierarchical method which is
   compatible to inter-domain path computation as describe in [RFC6805].

4.1. Mode of operation

   This section describes how PCInitiate and PCRpt messages are combined
   between PCE in order to setup inter-domain paths between a source
   domain(1) to a destination domain(n). S and D are respectively the
   source and destination of the inter-domain path. Domain(1) and
   domain(n) are different and connected through 0 or more intermediate
   domains denoted domain(i) with i = (2, n-1). Domains are directly
   connected when n = 2.

   First, the Parent PCE contacts its Child PCE as per [RFC6805] in
   order to compute the inter-domain path from S to D, where S and D are
   respectively a node in the domain(1) and domain(n). Path Key
   confidentiality as per RFC5520 [RFC5520] SHOULD be used to obfuscate
   the detailed ERO(i) of the different domains(i). The resulting ERO

is of the form (S, PKS(1), BN-ex(1), ..., BN-en(i), PKS(i), BN-ex(i), ..., BN-en(n), PKS(n), D) when Path Key is used and of the form {S, R(1,1), ..., R(1,k), BN-ex(1), ..., BN-en(i), R(i,1), ..., R(i,l), BN-ex(i), ..., BN-en(n), R(n,1), ..., R(n,m), D} otherwise.

The complete procedure with Path Key follow the different steps described below:

Step 1: Initialization

Parent PCE sends a PCInitiate message to child PCE(n) with an ERO = {PKS(n)} and End-Points = {BN-en(n), D}. Then, PCE(n) retrieves the ERO from the PKS(n) if necessary and sends to BN-en(n) a PCInitiate message with the ERO(n) = {BN-en(n), ..., D}, PST = TBD2 and End-Points Object = {BN-en(n), D} in order to inform the PCC BN-en(n) that this local LSP tunnel(n) is part of an inter-domain path. When the PCC BN-en(n) received the PCInitiate message from its PCE(n), it setup the local LSP tunnel from entry BN-en(n) to D by means of RSVP-TE signaling with the given ERO(n). Once the tunnel setup, it chooses a free label for the Stitching Label SL(n) and add a new entry in its MPLS L(F)IB with this SL(n) label. Then, it sends a PCRpt message to its PCE(n) with an RRO equal to {[LK(n), SL(n)], RRO(n)} and PLSP-ID(n). Once PCE(n) receives the PCRpt from the PCC BN-en(n) with the RRO, PLSP-ID and PST = TBD2, it sends to its Parent PCE a PCRpt containing the RRO equal to {[LK(n), SL(n)]} and PLSP-ID(n). PCE(n) MAY add PKS(n) in the RRO.

Steps i: Actions performed for all intermediate domains(i), for i = n-1 to 2

1. Parent PCE sends a PCInitiate message to Child PCE(i) with PST = TBD1, ERO = {PKS(i), [LK(i+1), SL(i+1)]} and End-Points = {BN-en(i), BN-ex(i)}

2. Then, PCE(i) retrieves the ERO from the PKS(i) if necessary and sends to the PCC BN-en(i) a PCInitiate message with ERO = {ERO(i), [LK(i+1), SL(i+1)]}, PST = TBD2 and End-Points Object = {BN-en(i), BN-ex(i)} in order to inform the PCC BN-en(i) that this local LSP tunnel(i) is part of an inter-domain path.

3. When the PCC BN-en(i) received the PCInitiate message from its PCE(i), it setup the local LSP tunnel from BN-en(i) to BN-ex(i) by means of RSVP-TE signaling with the given ERO(i).

4. Egress Control mechanism, as per RFC4003 section 2.1 [RFC4003], is used to instruct the egress node of domain(i), i.e. BN-ex(i) to forward packets belonging to this tunnel with the Stitching Label. Both Label Stitching and IP address of outgoing interface

are carried in the ERO = {..., [LK(i+1), SL(i+1)]} as the last
SubObject in conformance to [RFC4003]. So that, BN-ex(i)
installs in its MPLS L(F)IB the SWAP instruction to label SL(i+1)
with forward to LK(i+1) instead of the usual POP instruction.

5. Once the tunnel setup, PCC BN-en(i) chooses a free label for the
    Stitching Label SL(i) and add a new entry in its MPLS L(F)IB with
    this SL(i) label. Then, it sends a PCRpt message to its PCE(i)
    with an RRO equal to {[LK(i), SL(i)], RRO(i)} and PLSP-ID(i).

6. Once PCE(i) receives the PCRpt from the PCC BN-en(i) with the RRO
    and PST = TBD2, it sends to its Parent PCE a PCRpt message
    containing the RRO equal to {[LK(i), SL(i)]} and the PLSP-ID(i).
    PCE(i) MAY add PKS(i) in the RRO.

7. Once Parent PCE receives the PCRpt from the Child PCE(i), it
    stores the corresponding PLSP-ID for this inter-domain tunnel
    part

Steps n: Actions performed to the source domain(1)

Finally, Parent PCE sends a last PCInitiate message to Child PCE(1)
with PST = TBD1, ERO = {PKS(1), [LK(2), SL(2)]} and End-Points = {S,
BN-ex(1)}. In turn, Child PCE(1) sends a PCInitiate message to PCC
node S with ERO equal to {ERO(1), [LK(2), SL(2)]}, PST = 0 and End-
Points Object = {S, BN-ex(1)}. This time, the PST is equal to 0 as
the PCC S does not need to return a Stitching Label SL, i.e. it is
the head-end of the inter-domain path. Standard PCRpt message is
sent back to PCE(1) by the PCC node S. In turn, Child PCE(1) send a
final PCRpt message to the Parent PCE with the PSLP-ID(1). PCE(1)
MAY adds {S, BN-ex(1)} in the RRO as loose path.

4.2. Inter-domain LSP setup procedure completion failure

In case of error during LSP setup, PCRpt and or PCError messages MUST
be used to signal the problem to the Parent PCE. In particular, if
new PST values defined in this memo are not supported by the Child
PCE or the PCC, the Child PCE, receptively the PCC, MUST return a
PCErr message with Error-Type = 21 (Traffic engineering path setup
error) and Error-Value = 1 (Unsupported path setup type) to its
Parent PCE. If Child PCE(i) receives a PCInitiate message from its
Parent PCE without PST set to TBD1 or PST set to a value different
from TBD1, it MUST return a PCErr message with Error-Type = 21
(Traffic engineering path setup error) and Error-Value = 1
(Unsupported path setup type) to its Parent PCE.

If a Child PCE or a PCC don't return an RRO or an RRO without the
Stitching Label SL with the IP address of the associated link

following a PCInitiate message with PST set to TBD1, the Parent PCE, respectively the Child PCE, MUST return a PCErr message with Error-Type = 21 (Traffic engineering path setup error) and Error-Value = TBD5 (No Mandatory Stitching Label is present in the RRO).

In case of completion failure, the Parent PCE MUST MUST send a PCInitate message (R flag set in the SRP Object as per draft pce initiated lsp [RFC8281]) to delete this inter-domain path to the Child PCEs that already setup their respective part of the inter-domain tunnel. Child PCE(i) MUST remove their local LSP tunnel by means of PCInitiate message with R flag set to 1 to their PCC BN-en(i) and send back PCRpt message to the Parent PCE.

4.3. Example for Stateful H-PCE Stiching procedure

   Taking the sample hierarchical domain topology example from [RFC6805] as the reference topology for the entirety of this section.

```

|                                                                  |
 -----------------------------------------------------------------
```
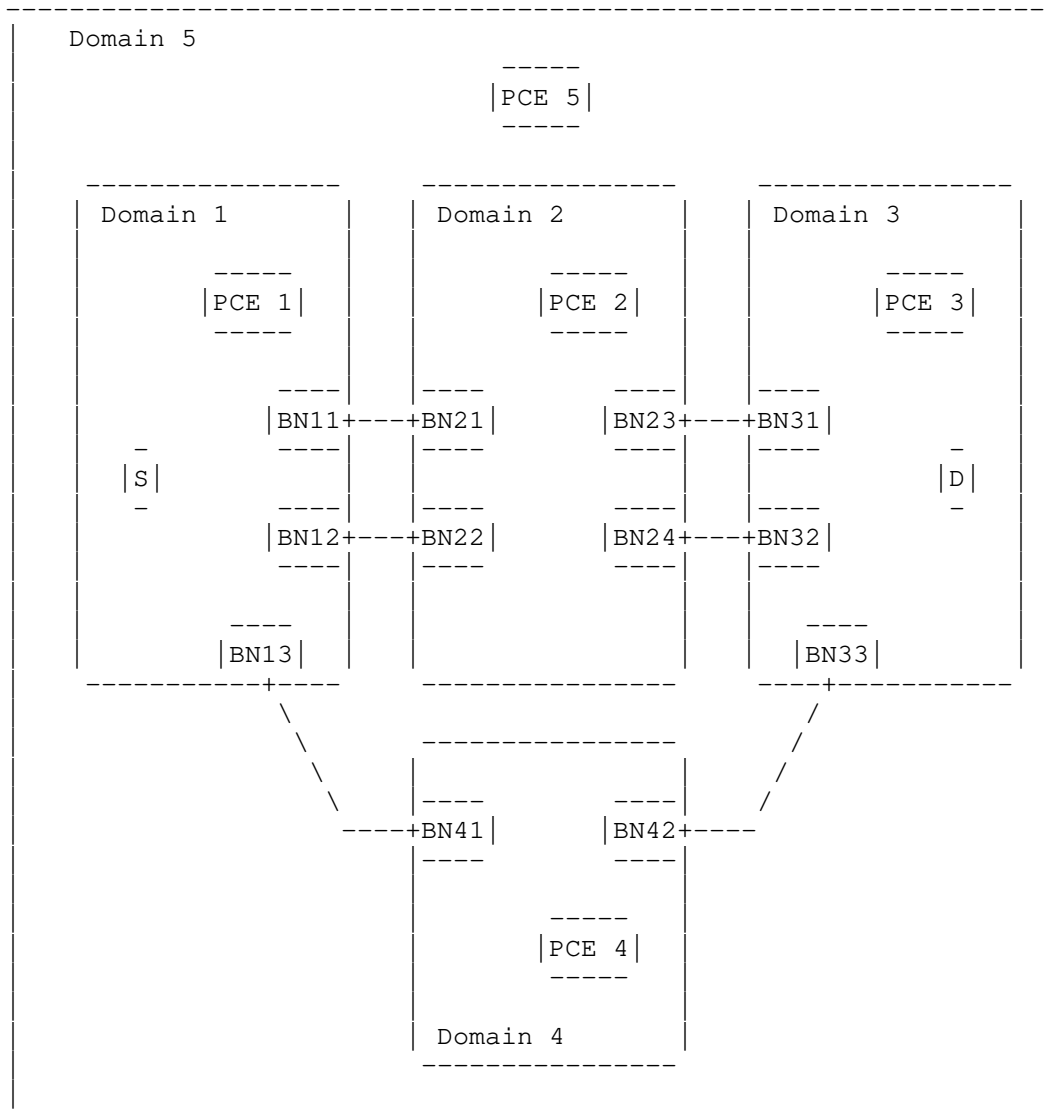

```
        Hierarchical domain topology from RFC6805
```

   Section 3.3.1 of [I-D.ietf-pce-stateful-hpce] describes the per-
   domain stitched LSP mode and list all the steps needed. To support
   SL based stitching, using the reference architecture described in
   Figure above, the steps are modified as follows (note that we do not
   use PKS in this example for simplicity):

Step 1: initialization

The P-PCE (PCE5) is requested to initiate a LSP. Steps 4 to 10 of section 4.6.2 of [RFC6805] are executed to determine the end to end path, which are broken into per-domain LSPs e.g. {S-BN41, BN41-BN33, BN33-D}

Step 2: LSP (BN33-D) at PCE3:

1. The P-PCE (PCE5) sends the initiate request to the child PCE (PCE3) via PCInitiate message for LSP (BN33-D) with ERO=(BN33..D) and PST = TBD1

2. The PCE3 further propagates the initiate message to BN33 with the ERO and PST = TBD2/TBD3 based on setup type

3. BN33 initiates the setup of the LSP as per the path and reports to the PCE3 the LSP status ("GOING-UP")

4. The PCE3 further reports the status of the LSP to the P-PCE (PCE5)

5. The node BN33 notifies the LSP state to PCE3 when the state is "UP" it also carry the stitching label (SL33) in RRO as (SL33,BN33..D)

6. The PCE3 further reports the status of the LSP to the P-PCE (PCE5) as well as carry the stitching label (SL33) in RRO as (LK33,SL33,BN33..D)

Step 3: LSP (BN41-BN33) at PCE4

1. The P-PCE (PCE5) sends the initiate request to the child PCE (PCE4) via PCInitiate message for LSP (BN41-BN33) with ERO=(BN41..BN42,LK33,SL33,BN33) and PST = TBD1

2. The PCE4 further propagates the initiate message to BN41 with the ERO and PST = TBD2/TBD3 based on setup type. In case of RSVP_TE, the node BN41 encode the stitching label SL33 as part of the ERO to make sure the node BN42 uses the label SL33 towards node BN33. In case of SR, the label SL33 is part of the label stack pushed at node BN41

3. BN41 initiates the setup of the LSP as per the path and reports to the PCE4 the LSP status ("GOING-UP")

4. The PCE4 further reports the status of the LSP to the P-PCE (PCE5)

5. The node BN41 notifies the LSP state to PCE4 when the state is
    "UP" it also carry the stitching label (SL41) in RRO as
    (LK41,SL41,BN41..BN33)

6. The PCE4 further reports the status of the LSP to the P-PCE
    (PCE5) as well as carry the stitching label (SL41) in RRO as
    (LK41,SL41,BN41..BN33)

Step 3: LSP (S-BN41) for PCE1

1. The P-PCE (PCE5) sends the initiate request to the child PCE
    (PCE1) via PCInitiate message for LSP (S-BN41) with
    ERO=(S..BN13,LK41,SL41,BN41)

2. The PCE1 further propagates the initiate message to node S with
    the ERO. In case of RSVP_TE, the node S encode the stitching
    label SL41 as part of the ERO to make sure the node BN13 uses the
    label SL41 towards node BN41. In case of SR, the label SL41 is
    part of the label stack pushed at node S

3. S initiates the setup of the LSP as per the path and reports to
    the PCE1 the LSP status ("GOING-UP")

4. The PCE1 further reports the status of the LSP to the P-PCE
    (PCE5)

5. The node S notifies the LSP state to PCE1 when the state is"UP"

6. The PCE1 further reports the status of the LSP to the P-PCE
    (PCE5)

In this way, per-domain LSP are stitched together using the stitching
label (SL). The per-domain LSP MUST be setup from the destination
domain towards the source domain one after the other.

Once the per-domain LSP is setup, the entry BN chooses a free label
for the Stitching Label SL and add a new entry in its MPLS L(F)IB
with this SL label. The SL from the destination domain is propagated
to adjacent transit domain, towards the source domain at each step.
This happens through the entry BN to C-PCE to the P-PCE and vice-
versa. In case of RSVP-TE, the entry BN further propagates the SL
label to the exit BN via RSVP-TE. In case of SR, the SL label is
pushed as part of the SR label stack.

5. Inter-domain LSP Management

    This section describe how inter-domain LSPs could be manage.

5.1. Identification of inter-domain tunnels

    First, in order to manage inter-domain tunnels composed by the
    stitching or nesting of local tunnels, it is important to identify
    them. For this purpose, PLSP-ID managed by PCEs are combined to one
    provided by PCCs to form global identifier as follow:

    o PCE(i) in the Backward Recursive method or the Child PCE in
       Hierarchical method MUST create a new unique PLSP-ID for this
       inter-domain LSP part and MUST send it in the PCRpt message, to
       the PCE(i-1), respectively the Parent PCE. In addition this new
       PLSP-ID MUST be associated to the one received from the PCC that
       instantiate the local tunnel part for further reference.

    o In Hierarchical mode, Parent PCE MUST store and associate the
       different PLSP-ID(i)s received from the different Child PCE(i)s in
       order to identify the different part of the inter-domain paths.

    o In Backward Recursive method, PCE(i) MUST store and associate its
       PLSP-ID(i) and the PLSP-ID(i+1) it received from the PCE(i+1).
       PCE(n) i.e. the last one in the chain, don't need to perform such
       association.

    Further reference to the inter-domain tunnel will use this PLSP-
    ID(i). In Backward Recursive method, PCE(i) MUST replace the PLSP-
    ID(i) by PLSP-ID(i+1) in the PCUpd, PCRpt or PCinitiate message
    before propagating it to PCE(i+1) and PCE(i) MUST replace the PLSP-
    ID(i+1) by PLSP-ID(i) in the PCRpt message before propagating it to
    the PCE(i-1). In Hierarchical method, Parent PCE MUST use the
    corresponding PLSP-ID(i) of the Child PCE(i).

5.2. Inter-domain association group

    In case of failure, a PCE(i) will received PCRpt messages from its
    PCCs and neighbors PCE(i+1) to synchronize the Inter-domain LSPs. In
    addition, it may received PCInitiate messages from its previous
    neighbors PCE(i-1) to re-initiate inter-domain tunnel part. As the
    PCE(i) may loose the PLSP-ID association, a new association group
    (within Association Object) is used to ease the association of the
    different part of the inter-domain tunnel: the local parts and the
    PCE to PCE parts. The use of the Association Object is MANDATORY in
    the Backward Recursive method and OPTIONAL in the Hierarchical
    method.

For that purpose, a new Inter-Domain Association Type with value TBD4 is defined. The first PCE in the Backward Recursive chain (the one which received the initial request) MUST send the PCInitiate message with an Association Object as follows:

o Association Type field MUST be set to new value TBD4

o Association ID MUST be set to a unique value. In case of Association ID field is too short or wraps, the first PCE MAY use the Extended Association ID to increase the number of association groups. The Association ID is managed locally by the PCE and does not need to be coordinated with neighbor or remote PCEs.

o IPV4 or IPv6 association source MUST be set to the IP address which identifies PCE(1) in domain(1).

o The Global Association Source TLV MUST be present and set with the ASN number of domain(1). It allows to create a globally unique association scope without putting constraint on operator's IP association source. Thus the IP Association Source is associated with the Global Association source to form a unique identifier.

o Extended Association ID MAY be present and MANDATORY if association ID is too short or wraps.

Subsequent PCE(i) for i = 2 to n, MUST send this Association Object as is to the local PCC and the neighbor PCE(i+1).

In case of error with the association group, PCErr message MUST be raised with Error = 26 (Association Error) and Error value set accordingly. A new Error value TBD6 is defined to identify association of inter-domain LSPs.

In Hierarchical method, parent PCE MAY act as initiator of the Association and send to the Child PCEs an Association Object that follows the same rules as for the Backward Recursive method. In turn, Child PCEs MUST propagate the Association Object to the local PCCs as is.

5.3. Inter-domain LSP management

For the Backward Recursive method, each domain manages their respective local LSP tunnel part of an inter-domain path independently of each other. In particular, Stitching Label(i) is managed by domain(i) and is of interest of domain(i-1) only. Thus, Stitching Label SL(i) is not supposed to be propagated to other domains. The same behavior apply to PLSP-ID(i). In Hierarchical method, the Parent PCE MUST ensure the correct distribution of

Stitching Label SL(i) to Child PCE(i-1. The PLSP-ID(i) is kept for
the usage of the Parent PCE and thus is not propagated. Only the
Association Object defined in section 5.2 is propagated if it is
present.

If a PCE(i) needs to modify its local LSP tunnel(i) with a PCUpd
message to the PCC BN-en(i), once PCRpt message received by the PCC
BN-en(i), it MUST sends a new PCRpt message to its neighbor PCE(i-1)
in Backward Recursive method, respectively to Parent PCE in
Hierarchical method, to advertise PCE(i-1) of the modification. In
this case PLSP-ID(i) is used to identify the inter-domain tunnel.
PCE(i-1), respectively the Parent PCE, MUST propagate the PCRpt
message if the modification imply the previous domain e.g. if the
PCRpt indicates that the Stitching Label SL(i) has changed.

PCE(1), respectively Parent PCE, could modify the inter-domain path.
For that purpose, it MUST sends a PCUpd message to its neighbor PCEs,
respectively Child PCE, using the PLSP-ID it received. Each PCE(i)
MUST process PCUpd message the same way they process PCInitiate
message as define in section 3.1 for Backward Recursive method and in
section 4.1 for Hierarchical method.

In case a failure appear in domain(i), e.g. tunnel becoming down,
PCE(i) MUST sends a PCRpt message to its neighbor PCE(i-1),
respectively its Parent PCE to advertise it of the problem in its
local part of the inter-domain path. Once PCE(1), respectively
Parent PCE, receives this PCRpt message indicating that the tunnel is
down, it is up to the PCE(1), respectively Parent PCE to take
appropriate correction e.g. start a new path computation to update
the ERO.

5.4. Modification of inter-domain LSP

   Modification of local LSP tunnel, BN-en(i) and BN-ex(i) is left for
   further study.

5.5. Removal of inter-domain LSP

   Deletion of inter-domain LSP is only possible by the inter-domain
   tunnel initiator i.e. PCE(1). For Backward Recursive method,
   PCInitiate message with R flag set to 1, PLSP-ID set accordingly to
   section 5.1 and the Association Object with R flag set to 1, is sent
   by PCE(1) to PCE(n) through PCE(i) and process the same way as
   describe in section 3.1. For Hierarchical method, PCInitiate message
   with R flag set to 1 is sent by the Parent PCE to each Child PCE(i)
   with corresponding PLSP-ID(i) and process accordingly to section 4.1.
   Each domain PCE(i) is responsible to delete its part of the tunnel
   and PCC MUST remove the Stitching label SL in its L(F)IB in addition

to the tunnel when it receives the PCInitiate message with the R flag
set to 1 and corresponding PLSP-ID. The Association Group MUST also
be removed by the PCC and PCE(i).

6. Applicability

The newly introduce Stitching Label SL serves to stitch or nest part
of local LSP tunnels to form an inter-domain path. Each domain is
free to decide if the tunnel is stitched or nested and how the tunnel
is enforced e.g. tough RSVP-TE or Segment Routing. However, the
Stitching Label principle is only compatible with MPLS data plane.
At the peering point, the Border Node BN-ex(i) MUST encapsulated the
packet with the Stitching Label i.e. the MPLS label prior to send
them to the next Border Node BN-en(i+1). Thus, only RSVP-TE and
Segment Routing over MPLS technology are detailed in the following
sections.

6.1. RSVP-TE

In case of RSVP-TE, the Border Node BN-ex(i) needs to received the
Stitching Label through the RSVP-TE message and install in its L(F)IB
a SWAP instruction to the Stitching Label and forward it to the next
Border Node BN-en(i+1). For that purpose, the Egress Control
mechanism, as per RFC4003 section 2.1 [RFC4003], is RECOMMENDED to
instruct the Border Node BN-ex(i) of this action. Other mechanisms
to program the L(F)IB could be used e.g. NetConf.

As the Stitching Label could serves to stitch or nest tunnels, a
domain(i) may decided to nest the incoming local LSP tunnel into a
higher hierarchy of tunnel for Traffic Engineering purpose. A PCE(i)
may also decided to group local LSP tunnels part of inter-domain
paths into a higher hierarchical tunnel to carry all these local LSP
tunnels from one BN-en(i) to one BN-ex(i).

6.2. Segment Routing

To use Segment Routing instead of RSVP-TE to setup the local LSP
tunnels as defined in draft pce segment routing
[I-D.ietf-pce-segment-routing], PCE(i) MUST send PCInitiate message
with PST = TBD3 instead of TBD2 to advertise their respective PCC
that the local LSP tunnels is enforce by means of Segment Routing.

Stitching Label SL(i) will be inserted in the label stack in order to
become the top label in the stack when the packet reach BN-en(i+1):
Thus, the Stitching Label SL(i) serves as entry FEC for BN-en(i+1) to
identify the packets that follow the next Segment Path. For that
purpose, BN-en(i+1) MUST install in its MPLS L(F)IB an instruction to
replace the incoming Stitching Label SL(i) by the label stack given

by the ERO(i+1) plus the Stitching Label SL(i+1). When a packet
reaches BN-ex(i), the last label in the stack before the label
SL(i+1) corresponds to a SID that allows to reach BN-en(i+1).

However, BN-ex(i) needs to know how to send the packets to BN-
en(i+1), in particular when there are multiple interfaces between
Border Nodes. Similar to the Egress Control mechanism used with
RSVP-TE, it is RECOMMENDED to used the inter-domain SID defined as
per draft Egress Peer Engineering
[I-D.ietf-idr-bgpls-segment-routing-epe] for that purpose. The
inter-domain SID is announced by BN-ex(i) to PCE(i) through BGP-LS
for each interface that connect BN-ex(i) to neighbors BN-en(i+1).
Thus, the label stack will end with {BN-ex(i) SID, Inter-Domain SID,
SL(i+1)} and processes as follows:

o Penultimate router pops its node SID, and sends the packet to the
   next node designated by the top label in the label stack i.e. the
   node SID of BN-ex(i)

o BN-ex(i) pops its node SID and looks up the next label in the
   stack, i.e. the inter-domain SID which corresponds to the
   interface to BN-en(i+1). BN-ex(i) pops again this inter-domain
   SID and send the packet to BN-ex(i) through the interface that
   correspond to the inter-domain SID.

o BN-en(i+1) pops the Stitching Label SL(i+1) and replaces it by the
   sub-sequent label stack.

Other mechanisms, e.g. NetConf, could be used to configure the
inter-domain SID on exit Border Nodes.

6.3. Mixing technology

During the instantiation procedure, if PCE(i) decides to reuse a
local tunnel which is not yet part of an inter-domain tunnel, it
SHOULD send a PCUpd message with PST = TBD2 to the PCC BN-en(i) in
order to request a Stitching Label SL(i) and new ERO(i) to include
the Stitching Label SL(i+1) and the associated link to the previous
ERO.

[RFC8453] describes framework for Abstraction and Control of TE
Networks (ACTN), where each Physical Network Controller (PNC) is
equivalent to C-PCE and P-PCE is the Multi-Domain Service Coordinator
(MDSC). The Per domain stitched LSP as per the Hierarchical PCE
architecture described in Section 3.3.1 and Section 4.1 of
[I-D.ietf-pce-stateful-hpce] is well suited for ACTN. The stitching
label (SL) mechanism as described in this document is well suited for
ACTN when per domain LSP needs to be stitched to form an E2E tunnel

or a VN Member. It is to be noted that certain VNs require isolation
from other clients. The stitching label mechanism described in this
document can be applicable to the VN isolation use-case by uniquely
identifying the concatenated stitching labels across multi-domain
only to a certain VN member or an E2E tunnel.

As each operator is free to enforce the tunnel with its technology
choice, it is a local policy decision for PCE(i) to instantiate the
local part of the end to end tunnel by either RSVP-TE or Segment
Routing. Thus, the PST value (i.e. TBD2 or TBD3) used in the
PCinitiate message sends by the PCE(i) to the local PCC is determined
by the local policy. How the local policy decision is set in PCE is
out of scope of this memo. This flexibility is allowed because the
stitching label principle allows to mix (data plane) technologies
between domains. For example, a domain(i) could used RSVP-TE while
domain(i+1) used Segment Routing, reciprocally. The Stitching Label
SL could serves to stitch indifferently Segment Path and RSVP-TE
tunnel. Indeed, Stitching Label SL will be part of the label stack
in order to become the top label in the stack when reaching the BN-
en(i+1). This Stitching Label could be swap as usual if the next
domain uses RSVP-TE tunnel. When the previous domain uses a RSVP-TE
tunnel, the Stitching Label will serve as key for the BN-en(i+1) to
determine which label stack it must use on top of the packet for a
Segment Routing path.

7. IANA Considerations

7.1. Path Setup Type values

   [RFC8408] defines the PATH-SETUP-TYPE TLV and requests that IANA
   creates a registry to manage the value of the PATH_SETUP_TYPE TLV's
   PST field. IANA is requested to allocate a new code point in the
   PCEP PATH_SETUP_TYPE TLV PST field registry, as follows:

   +-------+--+----------+
   | Value | Description | Reference |
   +-------+--+----------+
TBD1	Inter-Domain Traffic engineering end-to-end	This
	path is setup using Backward Recursive method	Document
TBD2	Inter-Domain Traffic engineering local path	This
	is setup using RSVP-TE	Document
TBD3	Inter-Domain Traffic engineering local path	This
	is setup using Segment Routing	Document
   +-------+--+----------+

7.2. Association Type value

   Draft pce association group [I-D.ietf-pce-association-group] defines
   the ASSOCIATION Object and requests that IANA creates a registry to
   manage the value of the Association Type value. IANA is requested to
   allocate a new code point in the PCEP ASSOCIATION GROUP TLV
   Association Type field registry, as follows:

   +-----------------+------------------------------+
   | Association Type | Description |
   +-----------------+------------------------------+
   | TBD4 | Inter-domain Association Group |
   +-----------------+------------------------------+

7.3. PCEP Error values

   IANA is requested to allocate code-points in the PCEP-ERROR Object
   Error Values registry for a new error-value of Error-Type 21 Invalid
   traffic engineering path setup and new error-value of Error-Type 26
   Association Error:

   +-----------+------------+-------------------------------------+
   | Error-Type | Error-Value | Description |
   +-----------+------------+-------------------------------------+
21	TBD5	Missing Mandatory Stitching Label in
		RRO
26	TBD6	Error in association of Inter-domain
		LSPs
   +-----------+------------+-------------------------------------+

8. Security Considerations

   No modification of PCE protocol (PCEP) has been requested by this
   draft which not introduce any issue regarding security. Concerning
   the PCEP session between PCEs, authors recommend to use the secure
   version of PCEP as defined in PCEPS [RFC8253] or use any other secure
   tunnel mechanism e.g. IPsec tunnel to transport PCEP session between
   PCE.

9. Acknowledgements

   The authors want to thanks PCE's WG members, and in particular Dhruv
   Dhody who greatly contributed to the Hierarchical section of this
   document.

10. Disclaimer
