MODERN

PASSWORD-BASED

AUTHENTICATION IN TLS

## A SHORT HISTORY

- ▶ Password-based authentication
  - ▶ \* without sending the password to the server
- ▶ SRP (Secure Remote Password) – RFC 2945
  - ▶ aPAKE (Augmented Password-Authenticated Key Exchange)
  - ▶ Widely implemented, used in [Apple iCloud](#), [ProtonMail](#), etc.
- ▶ Dragonfly – RFC 8492
  - ▶ SPEKE (Simple password exponential key exchange) derived
  - ▶ Independent submission

## SRP IN TLS (RFC 5054)

- ▶ Salt sent in the clear
  - ▶ Leads to pre-computation attack on password database
- ▶ Unsatisfying security analysis
- ▶ Finite fields only, no ECC
- ▶ Awkward fit for TLS 1.3
  - ▶ Needs missing messages (challenges outlined in draft-barnes-tls-pake)
  - ▶ Post-handshake requires renegotiation

# OPAQUE

*A new methodology for designing  
secure aPAKEs*

## OPAQUE OVERVIEW

- ▶ Methodology to combine an authenticated key exchange (such as TLS 1.3) with an OPRF (Oblivious Pseudo-Random Function) to get a Secure aPAKE
- ▶ Desirable properties
  - ▶ Security proof
  - ▶ Secure against pre-computation attacks
  - ▶ Efficient implementation based on ECC

## OPAQUE DEPENDENCIES OVERVIEW

- ▶ Underlying cryptographic work in CFRG
  - ▶ OPAQUE (draft-krawczyk-cfrg-opaque)
  - ▶ OPRF (draft-sullivan-cfrg-voprf)
  - ▶ Hash-to-curve (draft-irtf-cfrg-hash-to-curve)

## FUNDAMENTAL COMPONENTS / TERMINOLOGY

- ▶ The OPRF protocol allows the client to obtain a value based on the password and the server's private key without revealing the password to the server
- ▶  $\text{OPRF}(\text{pwd})$  is used to encrypt an envelope containing OPAQUE keys
  - ▶ The client's TLS 1.3-compatible private key
  - ▶ The server's TLS 1.3-compatible public key

## FUNDAMENTAL COMPONENTS / TERMINOLOGY

- ▶ Prime order group
  - ▶ e.g. The group of points on an Elliptic Curve such as P-256
  - ▶ Group elements will be denoted by capital letters such as P or Q
- ▶ Scalar multiplication
  - ▶ Adding a point to itself n times, such as  $P+P+\dots+P$  is denoted  $nP$
  - ▶ Scalars will be represented by lower-case letters
- ▶ Hash to group element (H2C)
  - ▶ Function that takes a scalar and outputs a random group element

## FUNDAMENTAL COMPONENTS / TERMINOLOGY

### ▶ OPRF Flow

## FUNDAMENTAL COMPONENTS / TERMINOLOGY

### ▶ OPRF Flow

# FUNDAMENTAL COMPONENTS / TERMINOLOGY

- ▶ The OPRF protocol allows the client to obtain a value based on the password and the server's private key without revealing the password to the server
- ▶  $\text{OPRF}(\text{pwd})$  is used to encrypt an envelope containing OPAQUE keys
  - ▶ The client's TLS 1.3-compatible private key
  - ▶ The server's TLS 1.3-compatible public key

## FUNDAMENTAL COMPONENTS / TERMINOLOGY

### ▶ OPRF Flow

# HIGH-LEVEL OVERVIEW

- ▶ User creates the envelope during password registration by running OPRF
- ▶ User proves knowledge of the password by being able to open the envelope and use the OPAQUE private key inside
- ▶ OPAQUE private keys used to authenticate handshake
  1. In place of PKI keys with a new Certificate Type
  2. Combined with TLS ephemerals in the key schedule using MQV or 3DH

## IN PLACE OF PKI KEYS: OPAQUE-SIGN

- ▶ OPAQUE keys are signature keys
- ▶ Client sends identity, OPRF\_1
- ▶ Server
  - ▶ Certificate message with OPRF\_2 in extension
  - ▶ CertificateRequest with Identity
- ▶ Key used for server CertificateVerify is server OPAQUE key
- ▶ Key used for client CertificateVerify is client OPAQUE key

### IN KEY SCHEDULE: OPAQUE-(3DH|MQV)

- ▶ OPAQUE keys are TLS 1.3 key shares
- ▶ Client sends identity, OPRF\_1, key\_share matching OPAQUE key type
- ▶ Server
  - ▶ EncryptedExtensions message with OPRF\_2 in extension
- ▶ Ephemeral-Ephemeral-Static-Static key exchange used as input to key schedule
  - ▶  $K \rightarrow \text{HKDF-Extract} = \text{Master Secret}$
- ▶ Optional certificate auth

## POST-HANDSHAKE AUTH: OPAQUE-SIGN IN EXPORTED AUTHENTICATOR

- ▶ Client to Server
  - ▶ Authenticator Request: Identity, OPRF\_1
- ▶ Server to Client
  - ▶ Exported Authenticator: OPRF\_2, Signature
  - ▶ Authenticator Request: Identity (linked to previous EA)
- ▶ Client to Server
  - ▶ Exported Authenticator: Signature

# PROPERTIES

- ▶ OPAQUE-Sign
  - ▶ No username privacy without ESNI-like mechanism
  - ▶ No simultaneous PKI auth
- ▶ OPAQUE-3DH, OPAQUE-MQV
  - ▶ No username privacy without ESNI-like mechanism
  - ▶ Optional PKI auth
- ▶ OPAQUE-Sign in Exported Authenticators
  - ▶ Username privacy
  - ▶ Optional PKI auth
  - ▶ Post-handshake auth through HTTP/2-like mechanisms
  - ▶ Extra round-trip

## RECAP

- ▶ New password-based authentication mechanism for TLS 1.3
- ▶ First Secure aPAKE protocol provably secure against pre-computation attacks
- ▶ Multiple constructions with desirable properties
  
- ▶ Interesting for the WG to pursue as an alternative to SRP?
