Abstract

The Content Delivery Networks Interconnection (CDNI) framework [RFC6707] defines a set of protocols to interconnect CDNs, to achieve multiple goals such as extending the reach of a given CDN to areas that are not covered by that particular CDN. One component that is needed to achieve the goal of CDNI described in [RFC7336] is the CDNI Request Routing Footprint & Capabilities Advertisement interface (FCI). [RFC8008] defines precisely the semantics of FCI and provides guidelines on the FCI protocol, but the exact protocol is explicitly outside the scope of that document. In this document, we follow the guidelines to define an FCI protocol using the Application-Layer Traffic Optimization (ALTO) protocol.

1. Introduction

The ability to interconnect multiple content delivery networks (CDNs) has many benefits, including increased coverage, capability, and reliability. The Content Delivery Networks Interconnection (CDNI) framework [RFC6707] defines four interfaces to achieve interconnection of CDNs: (1) the CDNI Request Routing Interface; (2) the CDNI Metadata Interface; (3) the CDNI Logging Interface; and (4) the CDNI Control Interface.

Among the four interfaces, the CDNI Request Routing Interface provides key functions, as specified in [RFC6707]: "The CDNI Request Routing interface enables a Request Routing function in an Upstream CDN to query a Request Routing function in a Downstream CDN to determine if the Downstream CDN is able (and willing) to accept the delegated Content Request. It also allows the Downstream CDN to control what should be returned to the User Agent in the redirection message by the upstream Request Routing function." On a high level, the scope of the CDNI Request Routing Interface, therefore, contains two main tasks: (1) determining if the downstream CDN (dCDN) is willing to accept a delegated content request; (2) redirecting the
content request coming from an upstream CDN (uCDN) to the proper entry point or entity in the downstream CDN.

Correspondingly, the request routing interface is broadly divided into two functionalities: (1) CDNI Footprint & Capabilities Advertisement interface (FCI); (2) CDNI Request Routing Redirection interface (RI). Since this document focuses on the first functionality, CDNI FCI, we will describe it in a more detailed way. CDNI FCI is an advertisement from a dCDN to a uCDN (push) or a query from a uCDN to a dCDN (pull) so that the uCDN knows whether it can redirect a particular user request to that dCDN.

A key component in defining CDNI FCI is defining objects describing the footprints and capabilities of a dCDN. Such objects are already in [RFC8008]. A protocol to transport and update such objects between a uCDN and a dCDN, however, is not defined. Hence, the scope of this document is to define such a protocol by introducing a new Application-Layer Traffic Optimization (ALTO) [RFC7285] service called "CDNI FCI Map Service".

There are multiple benefits in using ALTO as a transport protocol, as we discuss in Section 2.2.

The rest of this document is organized as follows. Section 2 provides non-normative background on both CDNI FCI and ALTO. Section 3 introduces the most basic service, called CDNI FCI Map, to realize CDNI FCI using ALTO. Section 4 demonstrates a key benefit of using ALTO: the ability to integrate CDNI FCI with ALTO network maps. Such integration provides a new granularity to describe footprints. Section 5 builds on filtered ALTO maps to introduce filtered CDNI FCI maps using capabilities so that a uCDN can get footprints with given capabilities instead of getting the full map which can be huge. Section 6 further shows a benefit of using ALTO: the ability to query footprint properties using ALTO unified properties. In this way, a uCDN can effectively fetch capabilities of some footprints in which it is interested. IANA and security considerations are discussed in Section 8 and Section 9 respectively.

Throughout this document, we use the terminology for CDNI defined in [RFC6707], [RFC8006], [RFC8008] and we use the terminology for ALTO defined in [RFC7285], [I-D.ietf-alto-unified-props-new].

2. Background

The design of CDNI FCI transport using ALTO depends on the understanding of both FCI semantics and ALTO. Hence, we start with a review of both.
2.1. Semantics of FCI Advertisement

The CDNI document on "Footprint and Capabilities Semantics" [RFC8008] defines the semantics of CDNI FCI, and provides guidance on what Footprint and Capabilities mean in a CDNI context and how a protocol solution should in principle look like. The definitions in [RFC8008] depend on [RFC8006]. Here we briefly summarize key related points of [RFC8008] and [RFC8006]. For a detailed discussion, the reader is referred to the RFCs.

- Footprint and capabilities are tied together and cannot be interpreted independently from each other. Hence, capabilities must be expressed on a per footprint basis. [RFC8008] integrates footprint and capabilities with an approach of "capabilities with footprint restrictions".

- Given that a large part of Footprint and Capabilities Advertisement will actually happen in contractual agreements, the semantics of CDNI Footprint and Capabilities advertisement refers to answering the following question: what exactly still needs to be advertised by the CDNI FCI? For instance, updates about temporal failures of part of a footprint can be useful information to convey via the CDNI request routing interface. Such information would provide updates on information previously agreed in contracts between the participating CDNs. In other words, the CDNI FCI is a means for a dCDN to provide changes/updates regarding a footprint and/or capabilities that it has prior agreed to serve in a contract with a uCDN. Hence, server push and incremental encoding will be necessary techniques.

- Multiple types of footprints (ipv4cidr, ipv6cidr, asn and countrycode) are defined in [RFC8006].

- A "Set of IP-prefixes" can contain both full IP addresses (i.e., a /32 for IPv4 and a /128 for IPv6) and IP prefixes with an arbitrary prefix length. There must also be support for multiple IP address versions, i.e., IPv4 and IPv6, in such a footprint.

- For all of these mandatory-to-implement footprint types, footprints can be viewed as constraints for delegating requests to a dCDN: A dCDN footprint advertisement tells the uCDN the limitations for delegating a request to the dCDN. For IP prefixes or ASN(s), the footprint signals to the uCDN that it should consider the dCDN a candidate only if the IP address of the request routing source falls within the prefix set (or ASN, respectively). The CDNI specifications do not define how a given uCDN determines what address ranges are in a particular ASN. Similarly, for country codes, a uCDN should only consider the dCDN
a candidate if it covers the country of the request routing source. The CDNI specifications do not define how a given uCDN determines the country of the request routing source. Multiple footprint constraints are additive, i.e., the advertisement of different types of footprint narrows the dCDN candidacy cumulatively.

The following capabilities are defined as "base" capabilities; that is, they are required in all cases and therefore constitute mandatory capabilities to be supported by the CDNI FCI: (1) Delivery Protocol; (2) Acquisition Protocol; (3) Redirection Mode; (4) Capabilities related to CDNI Logging; (5) Capabilities related to CDNI Metadata.

2.2. ALTO Background and Benefits

Application-Layer Traffic Optimization (ALTO) [RFC7285] is an approach for guiding the resource provider selection process in distributed applications that can choose among several candidate resource providers to retrieve a given resource. By conveying network layer (topology) information, an ALTO server can provide important information to "guide" the resource provider selection process in distributed applications. Usually, it is assumed that an ALTO server conveys information that these applications cannot or have difficulty to measure themselves [RFC5693].

Originally, ALTO was motivated by optimizing cross-ISP traffic generated by P2P applications [RFC5693]. Recently, however, ALTO is also being considered for improving the request routing in CDNs [I-D.jenkins-alto-cdn-use-cases]. The CDNI problem statement explicitly mentions ALTO as a candidate protocol for "actual algorithms for selection of CDN or Surrogate by Request-Routing systems" [RFC6707].

The following reasons make ALTO a suitable candidate protocol for downstream CDN selection as part of CDNI request routing and in particular for an FCI protocol:

ALTO is a protocol specifically designed to improve application layer traffic (and application layer connections among hosts on the Internet) by providing additional information to applications that these applications could not easily retrieve themselves. For CDNI, this is exactly the case: a uCDN wants to improve application layer CDN request routing by using dedicated information (provided by a dCDN) that the uCDN could not easily obtain otherwise. ALTO can help a uCDN to select a proper dCDN by first providing dCDNs’ capabilities as well as footprints (see
Section 3) and then providing costs of surrogates in a dCDN by ALTO cost maps.

- The semantics of an ALTO network map is an exact match for the needed information to convey a footprint by a downstream CDN, in particular if such a footprint is being expressed by IP-prefix ranges. Please see Section 4.

- Security: Identifications between uCDNs and dCDNs are extremely important. ALTO maps can be signed and hence provide inherent integrity protection. Please see Section 9.

- RESTful-Design: The ALTO protocol has undergone extensive revisions in order to provide a RESTful design regarding the client-server interaction specified by the protocol. A CDNI FCI interface based on ALTO would inherit this RESTful design. Please see Section 3.

- Error-handling: The ALTO protocol has undergone extensive revisions in order to provide sophisticated error-handling, in particular regarding unexpected cases. A CDNI FCI interface based on ALTO would inherit this thought-through and mature error-handling. Please see Section 5.

- Filtered map service: The ALTO map filtering service would allow a uCDN to query only for parts of an ALTO map. For example, filtered unified property map service can enable a uCDN to query properties of a part of footprints in an effective way (see Section 6).

- Server-initiated Notifications and Incremental Updates: When the footprint or the capabilities of a downstream CDN change (i.e., unexpectedly from the perspective of an upstream CDN), server-initiated notifications would enable a dCDN to directly inform an upstream CDN about such changes. Consider the case where – due to failure – part of the footprint of the dCDN is not functioning, i.e., the CDN cannot serve content to such clients with reasonable QoS. Without server-initiated notifications, the uCDN might still use a very recent network and cost map from dCDN, and therefore redirect requests to dCDN which it cannot serve. Similarly, the possibility for incremental updates would enable efficient conveyance of the aforementioned (or similar) status changes by the dCDN to the uCDN. The newest design of ALTO supports server pushed incremental updates [I-D.ietf-alto-incr-update-sse].

- Content Availability on Hosts: A dCDN might want to express CDN capabilities in terms of certain content types (e.g., codecs/formats, or content from certain content providers). The new
An endpoint property for ALTO would enable a dCDN to make such information available to an upstream CDN. This would enable a uCDN to determine if a given dCDN actually has the capabilities for a given request with respect to the type of content requested.

- Resource Availability on Hosts or Links: The capabilities on links (e.g., maximum bandwidth) or caches (e.g., average load) might be useful information for an upstream CDN for optimized downstream CDN selection. For instance, if a uCDN receives a streaming request for content with a certain bitrate, it needs to know if it is likely that a dCDN can fulfill such stringent application-level requirements (i.e., can be expected to have enough consistent bandwidth) before it redirects the request. In general, if ALTO could convey such information via new endpoint properties, it would enable more sophisticated means for downstream CDN selection with ALTO. ALTO Path Vector Extension [I-D.ietf-alt0-path-vector] is designed to allow ALTO clients to query information such as capacity regions for a given set of flows.

3. CDNI FCI Map

The ALTO protocol is based on an ALTO Information Service Framework which consists of several services, where all ALTO services are "provided through a common transport protocol, messaging structure and encoding, and transaction model" [RFC7285]. The ALTO protocol specification [RFC7285] defines several such services, e.g., the ALTO map service.

This document defines a new ALTO Service called "CDNI FCI Service" which conveys JSON objects of media type "application/alto-cdnifci+json". These JSON objects are used to transport BaseAdvertisementObject objects defined in [RFC8008]; this document specifies how to transport such BaseAdvertisementObject objects via the ALTO protocol with the ALTO "CDNI FCI Service". Similar to other ALTO services, this document defines the ALTO information resource for the "CDNI FCI Service" as follows.

3.1. Media Type

The media type of the CDNI FCI resource is "application/alto-cdnifci+json".

3.2. HTTP Method

A CDNI FCI resource is requested using the HTTP GET method.
3.3. Accept Input Parameters

None.

3.4. Capabilities

None.

3.5. Uses

The "uses" field SHOULD NOT appear unless the CDNI FCI resource depends on some ALTO information resources. If the CDNI FCI resource has some dependent resources, the resource IDs of its dependent resources MUST be included into the "uses" field. This document only defines one potential dependent resource for the CDNI FCI resource. See Section 4 for details of when and how to use it. The future documents may extend the CDNI FCI resource and allow other dependent resources.

3.6. Response

The "meta" field of a CDNI FCI response MUST include the "vtag" field defined in Section 10.3 of [RFC7285]. This field provides the version of the retrieved CDNI FCI map.

If a CDNI FCI response depends on an ALTO information resource, it MUST include the "dependent-vtags" field, whose value is an array to indicate the version tags of the resources used, where each resource is specified in "uses" of its IRD entry.

The data component of an ALTO CDNI FCI response is named "cdni-fci", which is a JSON object of type CDNIFCIData:

```json
object {
    CDNIFCIData cdni-fci-map;
} InfoResourceCDNIFCI : ResponseEntityBase;

object {
    BaseAdvertisementObject capabilities<1..*>;
} CDNIFCIData;
```

Specifically, a CDNIFCIData object is a JSON object that includes only one property named "capabilities", whose value is an array of BaseAdvertisementObject objects.

The syntax and semantics of BaseAdvertisementObject are well defined in Section 5.1 of [RFC8008]. A BaseAdvertisementObject object includes multiple properties, including capability-type, capability-
value and footprints, where footprints are defined in Section 4.2.2.2 of [RFC8006].

To be self-contained, we give a non-normative specification of BaseAdvertisementObject below. As mentioned above, the normative specification of BaseAdvertisementObject is in [RFC8008]

```
object {
    JSONString capability-type;
    JSONValue capability-value;
    Footprint footprints<0..*>;
} BaseAdvertisementObject;

object {
    JSONString footprint-type;
    JSONString footprint-value<1..*>;
} Footprint;
```

For each BaseAdvertisementObject, the ALTO client MUST interpret footprints appearing multiple times as if they appeared only once. If footprints in a BaseAdvertisementObject is null or empty or not appearing, the ALTO client MUST understand that the capabilities in this BaseAdvertisementObject have the "global" coverage.

Note: Further optimization of BaseAdvertisement objects to effectively provide the advertisement of capabilities with footprint restrictions is certainly possible. For example, these two examples below both describe that the dCDN can provide capabilities ["http/1.1", "https/1.1"] for the same footprints. However, the latter one is smaller in its size.

EXAMPLE 1

```
{  
    "meta" : {...},  
    "cdni-fci-map": { 
    "capabilities": [ 
    { 
        "capability-type": "FCI.DeliveryProtocol",  
        "capability-value": {  
        "delivery-protocols": [  
            "http/1.1"  
        ]  
    },  
    "footprints": [  
        <Footprint objects>  
    ]  
    ],  

EXAMPLE 2

Since such optimizations are not required for the basic interconnection of CDNs, the specifics of such mechanisms are outside the scope of this document.

3.7.  Examples

3.7.1.  IRD Example

Below is the information resource directory (IRD) of a simple, example ALTO server. The server provides both base ALTO information resources (e.g., network maps) and CDNI FCI related information resources (e.g., CDNI FCI resource), demonstrating a single, integrated environment.
Specifically, the IRD announces two network maps, one CDNI FCI resource without dependency, one CDNI FCI resource depending on a network map, one filtered CDNI FCI resource to be defined in Section 5, one unified property map including "cdni-fci-capabilities" as its entity property, one filtered unified property map including "cdni-fci-capabilities" and "pid" as its entity properties, and two update stream services (one for updating CDNI FCI resources, and the other for updating property maps).

3.7.2. Basic Example

In this example, we demonstrate a simple CDNI FCI resource; this resource does not depend on other resources. There are three BaseAdvertisementObjects in this map and these objects’ capabilities are http/1.1 delivery protocol, [http/1.1, https/1.1] delivery protocol and https/1.1 acquisition protocol respectively.

GET /cdnifci HTTP/1.1
Host: alto.example.com
Accept: application/alto-cdnifci+json,
       application/alto-error+json

HTTP/1.1 200 OK
Content-Length: XXX
Content-Type: application/alto-cdnifci+json

{ "meta" : { "vtag" : { "resource-id": "my-default-cdnifci",
                  "tag": "da65eca2eb7a10ce8b059740b0b2e3f8eb1d4785" } },
  "cdni-fci" : { "capabilities" : [ { "capability-type": "FCI.DeliveryProtocol",
                      "capability-value" : { "delivery-protocols" : [ "http/1.1" ] } } ] }

Seedorf, et al. Expires January 9, 2020
3.7.3. Incremental Updates Example

A benefit of using ALTO to provide CDNI FCI maps is that such maps can be updated using ALTO incremental updates. Below is an example that also shows the benefit of having both JSON merge patch and JSON patch to encode updates.

At first, an ALTO client requests updates for "my-default-cdnifci", and the ALTO server returns the "control-uri" followed by the full CDNI FCI response. Then when there is a change in the delivery-protocols in that 'http/2' is removed (from http/1.1 and http/2 to only http/1.1) due to maintenance of the http/2 clusters, the ALTO server uses JSON merge patch to encode the change and pushes the change to the ALTO client. Later on, the ALTO server notifies the ALTO client that "ipv4:192.0.2.0/24" is added into the footprint for
delivery-protocol http/1.1 by sending the change encoded by JSON
patch to the ALTO client.

POST /updates/cdnifci HTTP/1.1
Host: alto.example.com
Accept: text/event-stream,application/alto-error+json
Content-Type: application/alto-updatestreamparams+json
Content-Length: ###

{ "add": {
   "my-cdnifci-stream": {
      "resource-id": "my-default-cdnifci"
   }
}

HTTP/1.1 200 OK
Connection: keep-alive
Content-Type: text/event-stream

event: application/alto-updatestreamcontrol+json
data: {"control-uri":
data: "http://alto.example.com/updates/streams/3141592653589"}

data: { ... full CDNI FCI map ... }

data: application/merge-patch+json,my-default-cdnifci
data: { "meta": {
   "vtag": {
   "tag": "dasdfa10ce8b059740bddsfasd8eb1d47853716"
   }
   }
   , 
   "cdni-fci": {
   "capabilities": [
   { 
   "capability-type": "FCI.DeliveryProtocol",
   "capability-value": {
   "delivery-protocols": [
   "http/1.1"
   ]
   },
   "footprints": [
   <Footprint objects in only http/1.1>
   ]
   }
   }
The ALTO protocol defines a concept called PID to represent a group of IPv4 or IPv6 addresses which can be applied the same management policy. The PID is an alternative to the pre-defined CDNI footprint types (i.e., ipv4cidr, ipv6cidr, asn, and countrycode).

Specifically, a CDNI FCI resource can depend on an ALTO network map resource and use a new CDNI Footprint Type called "altopid" to compress its CDNI Footprint Payload.

"altopid" footprint type indicates that the corresponding footprint value is a list of PIDNames as defined in [RFC7285]. These PIDNames are references of PIDs in a network map resource. Hence a CDNI FCI map, the resource id of its dependent network map MUST be included in the "uses" field of its IRD entry, and the "dependent-vtag" field with a reference to this network map MUST be included in its response (see the example in Section 4.2.3).

4.2. Examples

4.2.1. IRD Example

We use the same IRD example given in Section 3.7.1.

4.2.2. ALTO Network Map for CDNI FCI Footprints Example

Below is an example network map whose resource id is "my-eu-netmap", and this map is referenced by the CDNI FCI example in Section 4.2.3.
GET /networkmap HTTP/1.1
Host: http://alto.example.com/myeunetmap
Accept: application/alto-networkmap+json,application/alto-error+json

HTTP/1.1 200 OK
Content-Length: XXX
Content-Type: application/alto-networkmap+json

{
"meta": {
  "vtag": [
    
  ],
},
"network-map": {
  "south-france": {
    
  },
  "germany": {
    "ipv4": [ "192.0.3.0/24"]
  }
}
}

4.2.3. ALTO PID Footprints in CDNI FCI

In this example, we show a CDNI FCI resource that depends on a network map described in Section 4.2.2.

GET /networkcdnifci HTTP/1.1
Host: alto.example.com
Accept: application/alto-cdnifci+json,application/alto-error+json
HTTP/1.1 200 OK
Content-Length: 618
Content-Type: application/alto-cdnifci+json

{
    "meta": {
        "dependent-vtags": [ 
            {
                "resource-id": "my-eu-netmap",
                "tag": "3ee2cb7e8d63d9fab71b34cbf764436315542e"
            }
        ],
    },
    "cdni-fci": {
        "capabilities": [
            {
                "capability-type": "FCI.DeliveryProtocol",
                "capability-value": [ "http/1.1" ]
            },
            {
                "capability-type": "FCI.DeliveryProtocol",
                "capability-value": [ "https/1.1" ],
                "footprints": [ 
                    {
                        "footprint-type": "altopid",
                        "footprint-value": [ "germany",
                                            "south-france"
                        ]
                    }
                ]
            }
        ]
    }
}

4.2.4. Incremental Updates Example

In this example, the ALTO client is interested in changes of "my-cdnifci-with-pid-footprints". Considering two changes, the first one is to change footprints of http/1.1 Delivery Protocol capability, and the second one is to remove "south-france" from the footprints of https/1.1 delivery protocol capability.

POST /updates/cdnifci HTTP/1.1
Host: alto.example.com
Accept: text/event-stream,application/alto-error+json
Content-Type: application/alto-updatestreamparams+json
Content-Length: ###

```
{ "add": {
   "my-network-map-cdnifci-stream": {
      "resource-id": "my-cdnifci-with-pid-footprints"
   }
}
```

5. Filtered CDNI FCI using Capabilities

Section 3 and Section 4 describe CDNI FCI Service which can be used to enable a uCDN to get capabilities with footprints constrains from dCDNs. However, always getting full CDNI FCI resources from dCDNs is very inefficient, hence we introduce a new service named "Filtered CDNI FCI Service" to allow a client to filter a CDNI FCI resource using a client-given set of capabilities. For each entry of the CDNI FCI response, only if the entry contains at least one of the client-given capabilities will it be returned to the client. The relationship between a filtered CDNI FCI resource and a CDNI FCI resource is similar to the relationship between a filtered network/cost map and a network/cost map.

5.1. Media Type

A filtered CDNI FCI resource uses the same media type defined for the CDNI FCI resource in Section 3.1.

5.2. HTTP Method

A filtered CDNI FCI resource is requested using the HTTP POST method.

5.3. Accept Input Parameters

The input parameters for a filtered CDNI FCI resource are supplied in the entity body of the POST request. This document specifies the input parameters with a data format indicated by the media type "application/alto-cdnifcifilter+json" which is a JSON object of type ReqFilteredCDNIIFCI, where:

data: {
  "op": "replace",
  "path": "/meta/vtag/tag",
  "value": "a10ce8b059740b0b2e3f8eb1d4785acd42231bfe"
},

} 

data: {
  "op": "remove",
  "path": "/cdni-fci/capabilities/2/footprints/0/
  footprint-value/1",
}

data: 

5. Filtered CDNI FCI using Capabilities

Section 3 and Section 4 describe CDNI FCI Service which can be used to enable a uCDN to get capabilities with footprints constrains from dCDNs. However, always getting full CDNI FCI resources from dCDNs is very inefficient, hence we introduce a new service named "Filtered CDNI FCI Service" to allow a client to filter a CDNI FCI resource using a client-given set of capabilities. For each entry of the CDNI FCI response, only if the entry contains at least one of the client-given capabilities will it be returned to the client. The relationship between a filtered CDNI FCI resource and a CDNI FCI resource is similar to the relationship between a filtered network/cost map and a network/cost map.

5.1. Media Type

A filtered CDNI FCI resource uses the same media type defined for the CDNI FCI resource in Section 3.1.

5.2. HTTP Method

A filtered CDNI FCI resource is requested using the HTTP POST method.

5.3. Accept Input Parameters

The input parameters for a filtered CDNI FCI resource are supplied in the entity body of the POST request. This document specifies the input parameters with a data format indicated by the media type "application/alto-cdnifcifilter+json" which is a JSON object of type ReqFilteredCDNIIFCI, where:
object {
    JSONString capability-type;
    JSONValue capability-value;
} CDNIFCICapability;

object {
    [CDNIFCICapability cdni-fci-capabilities<0..*>];
} ReqFilteredCDNIFCI;

with fields:

    capability-type: The same as Base Advertisement Object’s capability-type defined in Section 5.1 of [RFC8008].

    capability-value: The same as Base Advertisement Object’s capability-value defined in Section 5.1 of [RFC8008].

    cdni-fci-capabilities: A list of CDNI FCI capabilities defined in Section 5.1 of [RFC8008] for which footprints are to be returned. If a list is empty or not appearing, the ALTO server MUST interpret it as a request for the full CDNI FCI Map. The ALTO server MUST interpret entries appearing in a list multiple times as if they appeared only once.

5.4. Capabilities

None.

5.5. Uses

The resource ID of the CDNI FCI resource based on which the filtering is performed.

5.6. Response

The response MUST indicate an error, using ALTO protocol error handling specified in Section 8.5 of the ALTO protocol [RFC7285], if the request is invalid.

Specifically, a filtered CDNI FCI request is invalid if:

  o the value of "capability-type" is null;
  o the value of "capability-value" is null;
  o the value of "capability-value" is inconsistent with "capability-type".
When a request is invalid, the ALTO server MUST return an "E_INVALID_FIELD_VALUE" error defined in Section 8.5.2 of [RFC7285], and the "value" field of the error message SHOULD indicate this CDNI FCI capability.

The ALTO server returns a filtered CDNI FCI resource for a valid request. The format of a filtered CDNI FCI resource is the same as an full CDNI FCI resource (See Section 3.6.)

The returned CDNI FCI resource MUST contain only BaseAdvertisementObject objects whose CDNI capability object is the superset of one of CDNI capability object in "cdni-fci-capabilities". Specifically, that a CDNI capability object A is the superset of another CDNI capability object B means that these two CDNI capability objects have the same capability type and mandatory properties in capability value of A MUST include mandatory properties in capability value of B semantically. See Section 5.7.2 for a concrete example.

The version tag included in the "vtag" field of the response MUST correspond to the full CDNI FCI resource from which the filtered CDNI FCI resource is provided. This ensures that a single, canonical version tag is used independently of any filtering that is requested by an ALTO client.

5.7. Examples

5.7.1. IRD Example

We use the same IRD example by Section 3.7.1.

5.7.2. Basic Example

This example filters the full CDNI FCI resource in Section 3.7.2 by selecting only http/1.1 delivery protocol capability. Only the first two BaseAdvertisementObjects in the full map will be returned because the first object’s capability is http/1.1 delivery protocol and the second object’s capability is http/1.1 and https/1.1 delivery protocols which is the superset of http/1.1 delivery protocol.

```
POST /cdnifci/filtered HTTP/1.1
HOST: alto.example.com
Content-Type: application/cdnifilter+json
Accept: application/alto-cdnifci+json

{
    "cdni-fci-capabilities": [
        {
            "capability-type": "FCI.DeliveryProtocol",
        }
    ]
}
```
HTTP/1.1 200 OK
Content-Length: XXX
Content-Type: application/alto-cdnifci+json
{
  "meta": {
    "vtag": {
      "resource-id": "my-default-cdnifci",
      "tag": "da65eca2eb7a10ce8b059740b0b2e3f8eb1d4785"
    }
  },
  "cdni-fci": {
    "capabilities": [
      {
        "capability-type": "FCI.DeliveryProtocol",
        "capability-value": {
          "delivery-protocols": [
            "http/1.1"
          ]
        },
        "footprints": [
          <Footprint objects>
        ]
      },
      {
        "capability-type": "FCI.DeliveryProtocol",
        "capability-value": {
          "delivery-protocols": [
            "https/1.1",
            "http/1.1"
          ]
        },
        "footprints": [
          <Footprint objects>
        ]
      }
    ]
  }
}
5.7.3. Incremental Updates Example

In this example, the ALTO client only cares about the updates of one Delivery Protocol object whose value is "http/1.1". So it adds its limitation of capabilities in "input" field of the POST request.

    POST /updates/cdnifci HTTP/1.1
    Host: fcialtoupdate.example.com
    Accept: text/event-stream,application/alto-error+json
    Content-Type: application/alto-updatestreamparams+json
    Content-Length: ###

    { "add": { 
        "my-fci-stream": { 
            "resource-id": "my-filtered-cdnifci",
            "input": { 
                "cdni-fci-capabilities": [ 
                    { 
                        "capability-type": "FCI.DeliveryProtocol",
                        "capability-value": { 
                            "delivery-protocols": [ "http/1.1" ]
                        }
                    }
                ]
            }
        }
    }
}

HTTP/1.1 200 OK
Content-Type: text/event-stream

    event: application/alto-updatestreamcontrol+json
data: {"control-uri": 
data: "http://alto.example.com/updates/streams/3141592653590"}

    event: application/alto-cdnifci+json,my-fci-stream
data: { ... full filtered CDNI FCI map ... }

    event: application/merge-patch+json,my-fci-stream
data: {
    data: "meta": {
    data: "vtag": {
    data: "tag": "dasdfa10ce8b059740bddsfasd8e1d47853716" 
    data: }
}
6. Query Footprint Properties using ALTO Unified Property Service

Above sections describe how a uCDN can get the whole capabilities and footprints from dCDNs and how a uCDN can get the footprints of given capabilities. But there is another important case which is how a uCDN can get properties (i.e., capabilities) of given footprints.

The most natural way to solve this problem is to use ALTO unified property map defined in [I-D.ietf-alto-unified-props-new] since footprints can be easily presented as groups of entities and Filtered Property Maps are already well-defined. In this section, we describe how ALTO clients look up properties for individual footprints. We firstly describe how to represent footprint objects as unified property map entities, and then we provide examples of the full property map, the filtered property map and the incremental updates.

6.1. Representing Footprint Objects as Unified Property Map Entities

A footprint object has two properties: footprint-type and footprint-value. A footprint-value is an array of footprint values conforming to the specification associated with the registered footprint type
("ipv4cidr", "ipv6cidr", "asn", and "countrycode"). Since each unified property map entity has a unique address and each pair of footprint-type and a footprint value determines a group of unique addresses, a footprint object can be represented as a set of entities according to their different footprint-type and footprint values. However, [I-D.ietf-alto-unified-props-new] only defines IPv4 Domain and IPv6 Domain which represent footprint-type "ipv4cidr" and "ipv6cidr" respectively. To represent footprint-type "asn" and "countrycode", this document registers two new domains in Section 8.

Here gives an example of representing a footprint object as a set of unified property map entities.

```
{
    "footprint-type": "ipv4cidr",
    "footprint-value": ["192.0.2.0/24", "198.51.100.0/24"]
} --> "ipv4:192.168.2.0/24", "ipv4:198.51.100.0/24"
```

### 6.1.1. ASN Domain

This document specifies a new entity domain type in addition to the ones in [I-D.ietf-alto-unified-props-new]. ASN is the abbreviation of Autonomous System Number.

#### 6.1.1.1. Entity Domain Type

```
asn
```

#### 6.1.1.2. Domain-Specific Entity Addresses

The entity address of asn domain is encoded as a string consisting of the characters "as" (in lowercase) followed by the ASN [RFC6793].

#### 6.1.1.3. Hierarchy and Inheritance

There is no hierarchy or inheritance for properties associated with ASN.

### 6.1.2. COUNTRYCODE Domain

This document specifies a new entity domain type in addition to the ones in [I-D.ietf-alto-unified-props-new].

#### 6.1.2.1. Entity Domain Type

```
countrycode
```
6.1.2.2. Domain-Specific Entity Addresses

The entity address of countrycode domain is encoded as an ISO 3166-1 alpha-2 code [ISO3166-1] in lowercase.

6.1.2.3. Hierarchy and Inheritance

There is no hierarchy or inheritance for properties associated with country codes.

6.2. Examples

6.2.1. IRD Example

We use the same IRD example given by Section 3.7.1.

6.2.2. Property Map Example

This example shows a full unified property map in which entities are footprints and entities’ property is "cdni-fci-capabilities".
GET /propmap/full/cdnifci HTTP/1.1
HOST: alto.example.com
Accept: application/alto-propmap+json,application/alto-error+json

HTTP/1.1 200 OK
Content-Length: ###
Content-Type: application/alto-propmap+json

{
    "property-map": {
        "meta": {
            "dependent-vtags": [
                {
                    "resource-id": "my-default-cdnifci",
                    "tag": "7915dc0290c2705481c491a2b4ffbec482b3cf62"
                }
            ],
            "countrycode:us": {
                "my-default-cdnifci.cdni-fci-capabilities": [
                    {
                        "capability-type": "FCI.DeliveryProtocol",
                        "capability-value": {"delivery-protocols": ["http/1.1"]}
                    }
                ],
                "ipv4:192.0.2.0/24": {
                    "my-default-cdnifci.cdni-fci-capabilities": [
                        {
                            "capability-type": "FCI.DeliveryProtocol",
                            "capability-value": {"delivery-protocols": ["http/1.1"]}
                        }
                    ],
                    "ipv4:198.51.100.0/24": {
                        "my-default-cdnifci.cdni-fci-capabilities": [
                            {
                                "capability-type": "FCI.DeliveryProtocol",
                                "capability-value": {"delivery-protocols": ["http/1.1"]}
                            }
                        ],
                        "ipv6:2001:db8::/32": {
                            "my-default-cdnifci.cdni-fci-capabilities": [
                                {
                                    "capability-type": "FCI.DeliveryProtocol",
                                    "capability-value": {"delivery-protocols": ["http/1.1"]}
                                }
                            ],
                            "asn:as64496": {
                                "my-default-cdnifci.cdni-fci-capabilities": [
                                    {
                                        "capability-type": "FCI.DeliveryProtocol",
                                        "capability-value": {"delivery-protocols": ["http/1.1", "https/1.1"]}
                                    }
                                ]
                            }
                        }
                    }
                }
            }
        }
    }
}
6.2.3. Filtered Property Map Example

In this example, we use filtered property map service to get "pid" and "cdni-fci-capabilities" properties for two footprints "ipv4:192.0.2.0/24" and "ipv6:2001:db8::/32".

```json
POST /propmap/lookup/cdnifci-pid HTTP/1.1
HOST: alto.example.com
Content-Type: application/alto-propmapparams+json
Accept: application/alto-propmap+json,application/alto-error+json
Content-Length:

{
    "entities": [
        "ipv4:192.0.2.0/24",
        "ipv6:2001:db8::/32"
    ],
    "properties": [ "my-default-cdnifci.cdni-fci-capabilities",
                    "my-default-networkmap.pid" ]
}
```
HTTP/1.1 200 OK
Content-Length: ###
Content-Type: application/alto-propmap+json

{
  "property-map": {
    "meta": {
      "dependent-vtags": [
        {
          "resource-id": "my-default-cdnifci",
          "tag": "7915dc0290c2705481c491a2b4ffbec482b3cf62"},
        {
          "resource-id": "my-default-networkmap",
          "tag": "7915dc0290c2705481c491a2b4ffbec482b3cf63"}
      ],
      "ipv4:192.0.2.0/24": {
        "my-default-cdnifci.cdnifci-capabilities": {
          "capability-type": "FCI.DeliveryProtocol",
          "capability-value": {"delivery-protocols": ["http/1.1"]},
          "my-default-networkmap.pid": "pid1"
        },
        "ipv6:2001:db8::/32": {
          "my-default-cdnifci.cdnifci-capabilities": {
            "capability-type": "FCI.DeliveryProtocol",
            "capability-value": {"delivery-protocols": ["http/1.1"]},
            "my-default-networkmap.pid": "pid3"
          }
        }
      }
    }
  }
}

6.2.4. Incremental Updates Example

In this example, here is a client want to request updates for the properties "cdnifci-capabilities" and "pid" for two footprints "ipv4:192.0.2.0/24" and "countrycode:fr".

POST /updates/properties HTTP/1.1
Host: alto.example.com
Accept: text/event-stream,application/alto-error+json
Content-Type: application/alto-updatestreamparams+json
Content-Length: ###

{ "add": {
  "property-map-including-capability-property": {
    "resource-id": "filtered-cdnifci-property-map",
    "input": {
      "properties": ["my-default-cdnifci.cdnifci-capabilities",
                     "my-default-networkmap.pid"],
      "entities": [
"property-map": {  "meta": {
"dependent-vtags": [ {"resource-id": "my-default-cdnifci",  "tag": "7915dc0290c2705481c491a2b4ffbec482b3cf62"}, {"resource-id": "my-default-networkmap",  "tag": "7915dc0290c2705481c491a2b4ffbec482b3cf63"} ]},  "ipv4:192.0.2.0/24": { "my-default-cdnifci.cdnifci-capabilities": { "capability-type": "FCI.DeliveryProtocol",  "capability-value": {"delivery-protocols": ["http/1.1"]},  "my-default-networkmap.pid": "pid1" },  "ipv6:2001:db8::/32": { "my-default-cdnifci.cdnifci-capabilities": { "capability-type": "FCI.DeliveryProtocol",  "capability-value": {"delivery-protocols": ["http/1.1"]},  "my-default-networkmap.pid": "pid3" }  }
  }
} 6.2.4. Incremental Updates Example

In this example, here is a client want to request updates for the properties "cdnifci-capabilities" and "pid" for two footprints "ipv4:192.0.2.0/24" and "countrycode:fr".

POST /updates/properties HTTP/1.1
Host: alto.example.com
Accept: text/event-stream,application/alto-error+json
Content-Type: application/alto-updatestreamparams+json
Content-Length: ###

{ "add": {
"property-map-including-capability-property": {
  "resource-id": "filtered-cdnifci-property-map",
  "input": {

7. Design Decisions and Discussions

7.1. Table versus Map

A major design decision is if the Map service is suitable to provide the CDNI FCI. Current ALTO protocol uses Map service to provide network information, such as Network Maps, Cost Maps and Property Maps. Their common idea is to use Map-like data structure to represent information. It is different from the data structure of the CDNI FCI designed in [RFC8008], which suggests to use a set of BaseAdvertisementObjects to represent the CDNI FCI information, which actually is Table-like data structure. Both Table and Map can be represented as a set of data entries. But the difference of them is whether there is a primary key to index each data entry.

The main advantage of Map-like data design is to simplify the filter-based query. According to the discussion in [RFC8008] about benefits and concerns of advertisement-based design and query-based design, filter-based query can make the CDNI FCI scalable when the dCDN has thousands or tens of thousands of FCI objects. To transfer Table-like data to Map-like data, introducing the primary key is necessary. This document already defines two different solution to introduce the primary key: (1) set unique identifiers for CDNI capability objects; (2) set unique identifiers for CDNI footprint objects.

But the major concern of the Map-like data design is the redundancy. In Map-like data design, whatever we choose CDNI capability objects or footprint objects as the key, each data entry can only represent the 1-N relation. But there are lots of CDNI FCI objects have the N-N relation.

7.2. Filter-based Query versus Test-based Query

Another design decision is the query approach. ALTO is a query-based protocol. So using ALTO, uCDN should send a query request to the dCDN to pull the CDNI FCI proactively. To make the query efficiently instead of pulling the whole FCI data base every time, query approach design is very important.

This document only defines the filter-based query. A uCDN can specify a set of FCI capability objects or footprint objects to only
query the information including them. But there are two limitations: (1) uCDN cannot filter both of them simultaneously; (2) cannot specify complex filters.

One example is that uCDN wants to filter all CDNI FCI objects whose capabilities are in range C1 and footprints are in range F1, or capabilities are in range C2 and footprints are in range F2.

8. IANA Considerations

8.1. CDNI Metadata Footprint Type Registry

<table>
<thead>
<tr>
<th>Footprint Type</th>
<th>Description</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>altonetworkmap</td>
<td>A list of PID-names</td>
<td>RFCthis</td>
</tr>
</tbody>
</table>

Table 1: CDNI Metadata Footprint Type

[RFC Editor: Please replace RFCthis with the published RFC number for this document.]

8.2. ALTO Entity Domain Registry

As proposed in Section 9.2 of [I-D.ietf-alto-unified-props-new], "ALTO Entity Domain Registry" is requested. Besides, two new domains are to be registered, listed in Table 2.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Entity Address Encoding</th>
<th>Hierarchy &amp; Inheritance</th>
</tr>
</thead>
<tbody>
<tr>
<td>asn</td>
<td>See Section 6.1.1.2</td>
<td>None</td>
</tr>
<tr>
<td>countrycode</td>
<td>See Section 6.1.2.2</td>
<td>None</td>
</tr>
</tbody>
</table>

Table 2: ALTO Entity Domain

8.3. ALTO CDNI FCI Property Type Registry

The "ALTO CDNI FCI Property Type Registry" is required by the ALTO Entity Domain "asn", "countrycode", "pid", "ipv4" and "ipv6", listed in Table 3.
9. Security Considerations

As an extension of the base ALTO protocol [RFC7285], this document fits into the architecture of the base protocol, and hence the Security Considerations (Section 15) of the base protocol fully apply when this extension is provided by an ALTO server.

In the context of CDNI FCI, additional security considerations should be included as follows.

For authenticity and integrity of ALTO information, an attacker may disguise itself as an ALTO server for a dCDN, and provide false capabilities and footprints to a uCDN using the CDNI FCI map. Such false information may lead a uCDN to (1) select an incorrect dCDN to serve user requests or (2) skip uCDNs in good conditions.

For potential undesirable guidance from authenticated ALTO information, dCDNs can provide a uCDN with limited capabilities and smaller footprint coverage so that dCDNs can avoid transferring traffic for a uCDN which they should have to transfer.

For confidentiality and privacy of ALTO information, footprint properties integrated with ALTO unified property may expose network location identifiers (e.g., IP addresses or fine-grained PIDs).

For availability of ALTO services, an attacker may get the potential huge full CDNI FCI maps from an ALTO server in a dCDN continuously to run out of bandwidth resources of that ALTO server or may query filtered CDNI FCI services with complex capabilities to run out of computation resources of an ALTO server.

Protection strategies described in RFC 7285 can solve problems mentioned above well. However, the isolation of full/filtered CDNI FCI maps should also be considered.

If a dCDN signs agreements with multiple uCDNs, it must isolate full/filtered CDNI FCI maps for different uCDNs in that uCDNs will not redirect requests which should not have to served by this dCDN to this dCDN and it may not disclose extra information to uCDNs.
To avoid this risk, a dCDN may consider generating URIs of different full/filtered CDNI FCI maps by hashing its company ID, a uCDN’s company ID as well as their agreements. And it needs to avoid exposing all full/filtered CDNI FCI maps resources in one of its IRDs.

Abstract

This document is an extension to the base Application-Layer Traffic Optimization (ALTO) protocol. It extends the ALTO cost information service so that applications decide not only ‘where’ to connect, but also ‘when’. This is useful for applications that need to perform bulk data transfer and would like to schedule these transfers during an off-peak hour, for example. This extension introduces ALTO Cost Calendar, with which an ALTO Server exposes ALTO cost values in JSON arrays where each value corresponds to a given time interval. The time intervals as well as other Calendar attributes, are specified in the Information Resources Directory and ALTO Server responses.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

When the words appear in lower case, they are to be interpreted with their natural language meanings.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute
working documents as Internet-Drafts. The list of current Internet-
Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months
and may be updated, replaced, or obsoleted by other documents at any
time. It is inappropriate to use Internet-Drafts as reference
material or to cite them other than as "work in progress."

This Internet-Draft will expire on November 15, 2019.

1. Introduction

The base Application-Layer Traffic Optimization (ALTO) protocol specified in [RFC7285] provides guidance to overlay applications that need to select one or several hosts from a set of candidates able to provide a desired resource. This guidance is based on parameters that affect performance and efficiency of the data transmission between the hosts such as the topological distance. The goal of ALTO is to improve the Quality of Experience (QoE) in the application while optimizing resource usage in the underlying network infrastructure.

The ALTO protocol in [RFC7285] specifies a network map which defines groupings of endpoints in provider-defined network regions identified by Provider-defined Identifiers (PIDs). The Cost Map Service, Endpoint Cost Service (ECS) and Endpoint Ranking Service then provide ISP-defined costs and rankings for connections among the specified endpoints and PIDs and thus incentives for application clients to connect to ISP preferred locations, for instance, to reduce their costs. For the reasons outlined in the ALTO problem statement [RFC5693] and requirement AR-14 of [RFC6708], ALTO does not disseminate network metrics that change frequently. In a network, the costs can fluctuate for many reasons having to do with instantaneous traffic load or due to diurnal patterns of traffic demand or planned events such as network maintenance, holidays or highly publicized events. Thus, an ALTO application wishing to use the Cost Map and Endpoint Cost Service at some future time will have to estimate the state of the network at that time, a process that is, at best, fragile and brittle since the application does not have any visibility into the state of the network. The need of such future scheduling of large scale traffic that can be addressed by the ALTO protocol is motivated by Unicorn, a unified resource orchestration framework for multi-domain, geo-distributed data analytics, see [draft-xiang-alto-multidomain-analytics].

In case the ALTO Cost value changes are predictable over a certain period of time and the application does not require immediate data...
transfer, it can save time to get the whole set of cost values over this period in one single ALTO response. Using this set to schedule data transfers allows optimizing the network resources usage and QoE. ALTO Clients and Servers can also minimize their workload by reducing and accordingly scheduling their data exchanges.

This document extends [RFC7285] to allow an ALTO server to provide network costs for a given duration of time. A sequence of network costs across a time span for a given pair of network locations is named an "ALTO Cost Calendar". The Filtered Cost Map Service and Endpoint Cost Service are extended to provide Cost Calendars. In addition to this functional ALTO enhancement, we expect to further save network and storage resources by gathering multiple Cost Values for one Cost Type into one single ALTO Server response.

In this draft, an "ALTO Cost Calendar" is specified in terms of information resources capabilities that are applicable to time-sensitive ALTO metrics. An ALTO Cost Calendar exposes ALTO Cost Values in JSON arrays, see [RFC8259], where each value corresponds to a given time interval. The time intervals as well as other Calendar attributes are specified in the Information Resources Directory (IRD) and in the Server response to allow the ALTO Client to interpret the received ALTO values. Last, the extensions for ALTO Calendars are applicable to any Cost Mode and they ensure backwards compatibility with legacy ALTO clients.

In the rest of this document, Section 2 provides the design characteristics. Sections 3 and 4 define the formal specifications for the IRD and the information resources. IANA, security and operational considerations are addressed respectively in sections Section 5, Section 6 and Section 7.

2. Overview of ALTO Cost Calendars and terminology

2.1. Terminology

- ALTO transaction: A request/response exchange between an ALTO Client and an ALTO Server.
- Client: When used with a capital "C", this term refers to an ALTO Client.
- Calendar, Cost Calendar: When used with a capital "C", these terms refer to an ALTO Cost Calendar.
- Endpoint (EP): An endpoint is defined as in Section 2.1 of [RFC7285]. It can be, for example, a peer, a CDN storage location, a physical server involved in a virtual server-supported
application, a party in a resource-sharing swarm such as a computation grid, or an online multi-party game.

- Server: When used with a capital "S", this term refers to an ALTO Server.

2.2. ALTO Cost Calendar overview

An ALTO Cost Calendar provided by the ALTO Server provides 2 information items:

- an array of values for a given metric, where each value corresponds to a time interval, where the value array can sometimes be a cyclic pattern that repeats a certain number of times.

- attributes describing the time scope of the Calendar such as the size and number of the intervals and the date of the starting point of the Calendar, allowing an ALTO Client to interpret the values properly.

An ALTO Cost Calendar can be used like a "time table" to figure out the best time to schedule data transfers and also to proactively manage application traffic given predictable events such as expected spike in traffic due to crowd gathering (concerts, sports, etc.), traffic-intensive holidays and network maintenance. It may be viewed as a synthetic abstraction of, for example, real measurements gathered over previous periods on which statistics have been computed. However, like for any schedule, unexpected network incidents may require the current ALTO Calendar to be updated and resent to the ALTO Clients needing it. To this end, it is RECOMMENDED that ALTO Servers providing ALTO Calendars also provide the "ALTO Incremental Updates Using Server-Sent Events (SSE)" Service that is specified in [draft-ietf-alto-incr-update-sse]. Likewise, ALTO Clients capable of using ALTO Calendars SHOULD also use the SSE Service.

Most likely, the ALTO Cost Calendar would be used for the Endpoint Cost Service, assuming that a limited set of feasible Endpoints for a non-real time application is already identified, that they do not need to be accessed immediately and that their access can be scheduled within a given time period. The Filtered Cost Map Service is also applicable as long as the size of the Map allows it.
2.3. ALTO Cost Calendar information features

The Calendar attributes are provided in the Information Resources Directory (IRD) and in ALTO Server responses. The IRD announces attributes without date values in its information resources capabilities, whereas attributes with time dependent values are provided in the "meta" section of Server responses. The ALTO Cost Calendar attributes provide the following information:

- attributes to describe the time scope of the Calendar value array:
  - generic time zone,
  - applicable time interval size for each Calendar value, defined in seconds, that can cover a wide range of values.
  - duration of the Calendar: e.g., the number of intervals provided in the Calendar.

- "calendar-start-date": specifying when the Calendar starts, that is to which date the first value of the Cost Calendar is applicable.

- "repeated": an optional attribute indicating how many iterations of the provided Calendar will have the same values. The server may use it to allow the client to schedule its next request and thus save its own workload by reducing processing of similar requests.

Attribute "repeated" may take a very high value if a Calendar represents a cyclic value pattern that the Server considers valid for a long period. In this case, the Server will only update the Calendar values once this period has elapsed or if an unexpected event occurs on the network.

2.4. ALTO Calendar design characteristics

The extensions in this document and encode requests and responses using JSON [RFC8259].

Formally, the cost entries in an ALTO cost map can be any type of JSON value [RFC8259], (see the DstCosts object in Section 11.2.3.6 of [RFC7285]). However, that section states that an implementation of [RFC7285] SHOULD assume that the cost is a JSON number and fail to parse if it is not, unless the implementation is using an extension that signals a different data type. This document extends the definition of a legacy cost map given in [RFC7285] to allow a cost

entry to be an array of values, one per time interval, instead of just one number.

To realize an ALTO Calendar, this document extends: the IRD, the ALTO requests and responses for Cost Calendars.

This extension is designed to be light and to ensure backwards compatibility with base protocol ALTO Clients and with other extensions. It relies on section 8.3.7 "Parsing of Unknown Fields" of [RFC7285] that writes: "Extensions may include additional fields within JSON objects defined in this document. ALTO implementations MUST ignore unknown fields when processing ALTO messages."

The Calendar-specific capabilities are integrated in the information resources of the IRD and in the "meta" member of ALTO responses to Cost Calendars requests. A Calendar and its capabilities are associated with a given information resource and within this information resource with a given cost type. This design has several advantages:

- it does not introduce a new mode,
- it does not introduce new media types,
- it allows an ALTO Server to offer Calendar capabilities on a cost type, with attributes values adapted to each information resource.

The applicable Calendared information resources are:

- the Filtered Cost Map,
- the Endpoint Cost Map.

The ALTO Server can choose in which frequency it provides cost Calendars to ALTO Clients. It may either provide Calendar updates starting at the request date, or carefully schedule its updates so as to take profit from a potential repetition/periodicity of Calendar values.

2.4.1. ALTO Cost Calendar for all cost modes

An ALTO Cost Calendar is well-suited for values encoded in the "numerical" mode. Actually, a Calendar can also represent metrics in other modes considered as compatible with time-varying values. For example, types of Cost values such as JSONBool can also be calendared, as their value may be 'true' or 'false' depending on given time periods or likewise, values represented by strings, such as "medium", "high", "low", "blue", "open".
Note also that a Calendar is suitable as well for time-varying metrics provided in the "ordinal" mode, if these values are time-varying and the ALTO Server provides updates of cost value based preferences.

2.4.2. Compatibility with legacy ALTO Clients

The ALTO protocol extensions for Cost Calendars have been defined so as to ensure that Calendar capable ALTO Servers can provide legacy ALTO Clients with legacy information resources as well. That is a legacy ALTO Client can request resources and receive responses as specified in [RFC7285].

A Calendar-aware ALTO Server MUST implement the base protocol specified in [RFC7285].

As a consequence, when a metric is available as a Calendar array, it also MUST be available as a single value as required by [RFC7285]. The Server, in this case, provides the current value of the metric to either Calendar-aware Clients not interested in future or time-based values, or Clients implementing [RFC7285] only.

For compatibility with legacy ALTO Clients specified in [RFC7285], calendared information resources are not applicable for full cost maps for the following reason: a legacy ALTO client would receive a calendared cost map via an HTTP 'GET' command. As specified in section 8.3.7 of [RFC7285], it will ignore the Calendar Attributes indicated in the "meta" of the responses. Therefore, lacking information on Calendar attributes, it will not be able to correctly interpret and process the values of the received array of Calendar cost values.

Therefore, calendared information resources MUST be requested via the Filtered Cost Map Service or the Endpoint Cost Service, using a POST method.

3. ALTO Calendar specification: IRD extensions

The Calendar attributes in the IRD information resources capabilities carry constant dateless values. A Calendar is associated with an information resource rather than a cost type. For example, a Server can provide a "routingcost" Calendar for the Filtered Cost Map Service at a granularity of one day and a "routingcost" Calendar for the Endpoint Cost Service at a finer granularity but for a limited number of endpoints. An example IRD with Calendar specific features is provided in Section 3.3.
3.1. Calendar attributes in the IRD resources capabilities

A Cost Calendar for a given Cost Type MUST be indicated in the IRD by an object of type CalendarAttributes. A CalendarAttribute object is represented by the "calendar-attributes" member of a resource entry. Each CalendarAttributes object applies to a set of one or more cost types. A Cost Type name MUST appear no more than once in the "calendar-attributes" member of a resource entry; multiple appearances of a Cost Type name in CalendarAttributes object of the "calendar-attributes" member MUST cause the ALTO client to ignore any occurrences of this name beyond the first encountered occurrence.

It is RECOMMENDED for an ALTO Server that the time interval size specified in the IRD is the smallest possible one that it can provide. The Client can aggregate cost values on its own if it needs a larger granularity.

The encoding format for object CalendarAttributes, using JSON [RFC8259], is as follows:

```
CalendarAttributes calendar-attributes <1..*>

object{
  JSONString cost-type-names <1..*>;
  JSONNumber time-interval-size;
  JSONNumber number-of-intervals;
} CalendarAttributes;
```

- **"cost-type-names"**: An array of one or more elements indicating the cost-type-names in the IRD entry to which the capabilities apply.

- **"time-interval-size"**: The duration of an ALTO Calendar time interval in seconds. A "time-interval-size" value contains a JSONNumber. ALTO servers SHOULD use at least IEEE 754 double-precision floating point [IEEE.754.2008] to store this value. Example values are: 300, 7200, meaning that each Calendar value applies on a time interval that lasts respectively 5 minutes and 2 hours.

- **"number-of-intervals"**: The integer number of values of the Cost Calendar array, at least equal to 1.
- Attribute "cost-type-names" provides a better readability to the Calendar attributes specified in the IRD and avoids confusion with Calendar attributes of other cost-types.

- Multiplying 'time-interval-size' by 'number-of-intervals' provides the duration of the provided Calendar. For example, an ALTO Server may provide a Calendar for ALTO values changing every 'time-interval-size' equal to 5 minutes. If 'number-of-intervals' has the value 12, then the duration of the provided Calendar is "1 hour".

3.2. Calendars in a delegate IRD

It may be useful to distinguish IRD resources supported by the base ALTO protocol from resources supported by its extensions. To achieve this, one option, is that a "root" ALTO Server implementing base protocol resources delegates "specialized" information resources such as the ones providing Cost Calendars, to another ALTO Server running in a subdomain that is specified with its URI in the "root" ALTO Server. This option is described in Section 9.2.4 "Delegation using IRDs" of [RFC7285].

This document provides an example, where a "root" ALTO Server runs in a domain called "alto.example.com". It delegates the announcement of Calendars capabilities to an ALTO Server running in a subdomain called "custom.alto.example.com". The location of the "delegate Calendar IRD" is assumed to be indicated in the "root" IRD by the resource entry: "custom-calendared-resources".

Another advantage is that some Cost Types for some resources may be more advantageous as Cost Calendars and it makes few sense to get them as a single value. For example, Cost Types with predictable and frequently changing values, calendared in short time intervals such as a minute.

3.3. Example IRD with ALTO Cost Calendars

This section provides an example ALTO Server IRD that supports various cost metrics and cost modes. In particular, since [RFC7285] makes it mandatory, the Server uses metric "routingcost" in the "numerical" mode.

For illustrative purposes, this section introduces 3 other fictitious example metrics and modes that should be understood as examples and should not be used or considered as normative.

The cost type names used in the example IRD as thus as follows:
"num-routingcost": refers to metric "routingcost" in the numerical mode as defined in [RFC7285] and registered with IANA.

"num-owdelay": refers to fictitious performance metric "owdelay" in the "numerical" mode, to reflect the one-way packet transmission delay on a path. A related performance metric is currently under definition in [draft-ietf-alto-performance-metrics].

"num-throughputrating": refers to fictitious metric "throughputrating" in the "numerical" mode, to reflect the provider preference in terms of end to end throughput.

"string-servicestatus": refers to fictitious metric "servicestatus" in some example mode "string", to reflect the availability, defined by the provider, of for instance path connectivity.

The example IRD includes 2 particular URIs providing Calendars:

- "https://custom.alto.example.com/calendar/costmap/filtered": a filtered cost map in which Calendar capabilities are indicated for cost type names: "num-routingcost", "num-throughputrating" and "string-servicestatus",

- "https://custom.alto.example.com/calendar/endpointcost/lookup": an endpoint cost map in which Calendar capabilities are indicated for cost type names: "num-routingcost", "num-owdelay", "num-throughputrating", "string-servicestatus".

The design of the Calendar capabilities allows that some Calendars on a cost type name are available in several information resources with different Calendar Attributes. This is the case for Calendars on "num-routingcost", "num-throughputrating" and "string-servicestatus", available in both the Filtered Cost map and Endpoint Cost Service, but with different time interval sizes for "num-throughputrating" and "string-servicestatus".

                    {"cost-type-names": ["num-routingcost",
                        "num-throughputrating"],
                        "time-interval-size": 7200,
                        "number-of-intervals": 12},
                    {"cost-type-names": ["string-servicestatus"],
                        "time-interval-size": 1800,
                        "number-of-intervals": 48}
                ]
            },
            "uses": ["my-default-network-map"]
        }
    }
}
In this example IRD, for the Filtered Cost Map Service:

- the Calendar for "num-routingcost" and "num-throughputrating" is an array of 12 values each provided on a time interval lasting 7200 seconds (2 hours).
- the Calendar for "string-servicestatus": is an array of 48 values each provided on a time interval lasting 1800 seconds (30 minutes).

For the Endpoint Cost Service:
4. ALTO Calendar specification: Service Information Resources

This section documents the individual information resources defined to provide the calendared information services defined in this document.

The reference time zone for the provided time values is UTC. The option chosen to express the time format is the HTTP header fields format specified in [RFC7231] where, however, timestamps are still displayed with the acronym "GMT" rather than "UTC":

Date: Tue, 15 Nov 2014 08:12:31 GMT

The value of a Calendar time interval size is expressed in seconds.

4.1. Calendar extensions for Filtered Cost Maps (FCM)

A legacy ALTO client requests and gets Filtered Cost Map responses as specified in [RFC7285].

4.1.1. Calendar extensions in Filtered Cost Map requests

The input parameters of a "legacy" request for a filtered cost map, defined by object ReqFilteredCostMap in section 11.3.2 of [RFC7285], are augmented with one additional member.

A Calendar-aware ALTO client requesting a Calendar on a given Cost Type for a filtered cost map resource having Calendar capabilities MUST add the following field to its input parameters:

JSONBoolean calendared<1..*>

This field is an array of 1 to N boolean values, where N is the number of requested metrics. Each entry corresponds to the requested metric at the same array position. Each boolean value indicates
whether or not the ALTO Server should provide the values for this Cost Type as a Calendar. The array MUST contain exactly N boolean values, otherwise, the Server returns an error.

This field MUST NOT be included if no member "calendar-attributes" is specified in this information resource.

If a value of field 'calendared' is 'true' for a cost type name for which no Calendar attributes have been specified: an ALTO Server, whether it implements the extensions of this document or only implements [RFC7285], MUST ignore it and return a response with a single cost value as specified in [RFC7285].

If this field is not present, it MUST be assumed to have only values equal to 'false'.

A Calendar-aware ALTO client that supports requests for only one cost type at a time and wants to request a Calendar MUST provide an array of 1 element:

"calendared" : [true];

A Calendar-aware ALTO client that supports requests for more than one Cost Types at a time, as specified in [RFC8189] MUST provide an array of N values set to 'true' or 'false', depending whether it wants the applicable Cost Type values as a single or calendared value.

4.1.2. Calendar extensions in Filtered Cost Map responses

In a calendared ALTO Filtered Cost Map, a cost value between a source and a destination is a JSON array of JSON values. An ALTO Calendar values array has a number of values equal to the value of member "number-of-intervals" of the Calendar attributes that are indicated in the IRD. These attributes will be conveyed as metadata in the Filtered Cost Map response. Each element of the array is valid for the time-interval that matches its array position.

The FCM response conveys metadata among which:

- some are not specific to Calendars and ensure compatibility with [RFC7285] and [RFC8189]
- some are specific to Calendars.

The non Calendar specific "meta" fields of a calendared Filtered Cost Map response MUST include at least:
o if the ALTO Client requests cost values for one Cost Type at a
time only: the "meta" fields specified in [RFC7285] for these
information service responses:
   * "dependent-vtags ",
   * "cost-type" field.

o if the ALTO Client implements the Multi-Cost ALTO extension
specified in [RFC8189] and requests cost values for several Cost
Types at a time: the "meta" fields specified in [RFC8189] for
these information service responses:
   * "dependent-vtags ",
   * "cost-type" field with value set to '{ }', for backwards
compatibility with [RFC7285].
   * "multi-cost-types" field.

If the client request does not provide member "calendared" or if it
provides it with a value equal to 'false', for all the requested Cost
Types, then the ALTO Server response is exactly as specified in
[RFC7285] and [RFC8189].

If the value of member "calendared" is equal to 'false' for a given
requested Cost Type, the ALTO Server MUST return, for this Cost Type,
a single cost value as specified in [RFC7285].

If the value of member "calendared" is equal to 'true' for a given
requested Cost Type, the ALTO Server returns, for this Cost Type, a
cost value Calendar as specified above in this section. In addition
to the above cited non Calendar specific "meta" members, the Server
MUST provide a Calendar specific metadata field.

The Calendar specific "meta" field that a calendared Filtered Cost
Map response MUST include is a member called "calendar-response-
attributes", that describes properties of the Calendar and where:
   o member "calendar-response-attributes" is an array of one or more
     objects of type "CalendarResponseAttributes".
   o each "CalendarResponseAttributes" object in the array is specified
     for one or more Cost Types for which the value of member
     "calendared" is equal to 'true' and for which a Calendar is
     provided for the requested information resource.
the "CalendarResponseAttributes" object that applies to a cost
type name has a corresponding "CalendarAttributes" object defined
for this cost type name in the IRD capabilities of the requested
information resource. The members of a
"CalendarResponseAttributes" object include all the members of the
corresponding "CalendarAttributes" object.

The format of member "CalendarResponseAttributes is defined as
follows:

```
CalendarResponseAttributes calendar-response-attributes <1..*>;

object{
  [JSONString cost-type-names <1..*>];
  JSONString calendar-start-time;
  JSONNumber time-interval-size;
  JSONNumber number-of-intervals;
  [JSONNumber repeated;]
} CalendarResponseAttributes;
```

Object CalendarResponseAttributes has the following attributes:

- "cost-type-names": is an array of one or more cost-type-names to
  which the capabilities apply and for which a Calendar has been
  requested. The value of this member is a subset of the "cost-
type-names" array specified in the corresponding IRD Calendar
  attributes.

- "calendar-start-time": indicates the date at which the first value
  of the Calendar applies. The value provided for the "calendar-
  start-time" attribute SHOULD NOT be later than the request date.

- "time-interval-size": as specified in Section 3.1 and with the
  same value.

- "number-of-intervals": as specified in Section 3.1 and with the
  same value.

- "repeated": is an optional field provided for Calendars. It is an
  integer N greater or equal to '1' that indicates how many
  iterations of the Calendar value array starting at the date
  indicated by "calendar-start-time" have the same values. The
  number N includes the provided iteration.

For example: suppose the "calendar-start-time" member has value "Mon,
30 Jun 2014 at 00:00:00 GMT", the "time-interval-size" member has
value '3600', the "number-of-intervals" member has value '24' and the
value of member "repeated" is equal to '4'. This means that the

Calendar values are the same on Monday, Tuesday, Wednesday and Thursday on a period of 24 hours starting at 00:00:00 GMT. The ALTO Client thus may use the same Calendar for the next 4 days starting at "calendar-start-time" and will only need to request a new one for Friday July 4th at 00:00:00 GMT.

Attribute "repeated" may take a very high value if a Calendar represents a cyclic value pattern that the Server considers valid for a long period and hence will only update once this period has elapsed or if an unexpected event occurs on the network. In the latter case, the client will be notified if it uses the "ALTO Incremental Updates Using Server-Sent Events (SSE)" Service, specified in [draft-ietf-alto-incr-update-sse]. See also discussion in Section 7 "Operational Considerations".

4.1.3. Use case and example: FCM with a bandwidth Calendar

An example of non-real time information that can be provisioned in a Calendar is the expected path throughput. While the transmission rate can be measured in real time by end systems, the operator of a data center is in the position of formulating preferences for given paths, at given time periods to avoid traffic peaks due to diurnal usage patterns. In this example, we assume that an ALTO Client requests a Calendar of network provider defined throughput ratings, as specified in the IRD, to schedule its bulk data transfers as described in the use cases.

In the example IRD, Calendars for cost type name "num-throughputrating" are available for the information resources: "filtered-cost-calendar-map" and "endpoint-cost-calendar-map". The ALTO Client requests a Calendar for "num-throughputrating" via a POST request for a filtered cost map.

We suppose in the present example that the ALTO Client sends its request on Tuesday July 1st 2014 at 13:15. The Server returns Calendars with arrays of 12 numbers for each source and destination pair. The values for metric "throughputrating", in this example, are assumed to be encoded in 2 digits. For representation brevity, the arrays in the provided example are symbolized by expression "[v1, v2, ... v12]", that is otherwise not valid in JSON. The value of field "Content-Length" in the responses is computed as if "throughputrating" values were encoded in 2 digits. The same type of symbolization is used in the other example Server responses in Section 4.2.3 and Section 4.2.4 of this document.
POST /calendar/costmap/filtered HTTP/1.1
Host: alto.example.com
Content-Length: 208
Content-Type: application/alto-costmapfilter+json
Accept: application/alto-costmap+json, application/alto-error+json

{
  "cost-type": {"cost-mode": "numerical",
                "cost-metric": "throughputrating"},
  "calendared": [true],
  "pids": {
    "srcs": ["PID1", "PID2"],
    "dsts": ["PID1", "PID2", "PID3"]
  }
}

HTTP/1.1 200 OK
Content-Length: 815
Content-Type: application/alto-costmap+json

{
  "meta": {
    "dependent-vtags": [
      {"resource-id": "my-default-network-map",
       "tag": "3ee2cb7e8d63d9fab71b9b34cbf764436315542e"
      }]
  },
  "cost-type": {"cost-mode": "numerical",
                "cost-metric": "throughputrating"},
  "calendar-response-attributes": [
    {"calendar-start-time": "Tue, 1 Jul 2014 13:00:00 GMT",

              "PID3": [v1,v2, ... v12]}
    "PID3": {"PID1": [v1,v2, ... v12],
              "PID2": [v1,v2, ... v12],
              "PID3": [v1,v2, ... v12]}
  }
}
4.2. Calendar extensions in the Endpoint Cost Service

This document extends the Endpoint Cost Service, as defined in (11.5.1) of [RFC7285], by adding new input parameters and capabilities, and by returning JSONArrays instead of JSONNumbers as the cost values. The media type (11.5.1.1) and HTTP method (11.5.1.2) are unchanged.

4.2.1. Calendar specific input in Endpoint Cost requests

The extensions to the requests for calendared Endpoint Cost Maps are the same as for the Filtered Cost Map Service, specified in section Section 4.1.1 of this draft.

The ReqEndpointCostMap object for a calendared ECM request will have the following format:

```json
object {
  [CostType cost-type;]
  [CostType multi-cost-types<1..*>;]
  [JSONBoolean calendared<1..*>;]
  EndpointFilter endpoints;
} ReqEndpointCostMap;
```

```json
object {
  [TypedEndpointAddr srcs<0..*>;]
  [TypedEndpointAddr dsts<0..*>;]
} EndpointFilter;
```

4.2.2. Calendar attributes in the Endpoint Cost response

The "meta" field of a calendared Endpoint Cost response MUST include at least:

- if the ALTO Client supports cost values for one Cost Type at a time only: the "meta" fields specified in (11.5.1.6) of [RFC7285] for the Endpoint Cost response:
  * "cost-type" field.

- if the ALTO Client supports cost values for several Cost Types at a time, as specified in [RFC8189] : the "meta" fields specified in [RFC8189] for the the Endpoint Cost response:
  * "cost-type" field with value set to ‘{}’, for backwards compatibility with [RFC7285].
If the client request does not provide member "calendared" or if it provides it with a value equal to 'false', for all the requested Cost Types, then the ALTO Server response is exactly as specified in [RFC7285] and [RFC8189].

If the ALTO client provides member "calendared" in the input parameters with a value equal to 'true' for given requested Cost Types, the "meta" member of a calendared Endpoint Cost response MUST include, for these Cost Types, an additional member "calendar-response-attributes", the contents of which obey the same rules as for the Filtered Cost Map Service, specified in Section 4.1.2. The Server response is thus changed as follows, w.r.t [RFC7285] and [RFC8189]:

- the "meta" member has one additional field "CalendarResponseAttributes", as specified for the Filtered Cost Map Service,
- the calendared costs are JSONArrays instead of the JSONNumbers format used by legacy ALTO implementations. All arrays have a number of values equal to 'number-of-intervals'.

If the value of member "calendared" is equal to 'false' for a given requested Cost Type, the ALTO Server MUST return, for this Cost Type, a single cost value as specified in [RFC7285].

4.2.3. Use case and example: ECS with a routingcost Calendar

Let us assume an Application Client is located in an end system with limited resources and having access to the network that is either intermittent or provides an acceptable quality in limited but predictable time periods. Therefore, it needs to both schedule its resource-greedy networking activities and its ALTO transactions.

The Application Client has the choice to trade content or resources with a set of Endpoints and needs to decide with which one it will connect and at what time. For instance, the Endpoints are spread in different time-zones, or have intermittent access. In this example, the 'routingcost' is assumed to be time-varying, with values provided as ALTO Calendars.

The ALTO Client associated with the Application Client queries an ALTO Calendar on 'routingcost' and will get the Calendar covering the 24 hours time period "containing" the date and time of the ALTO client request.
For Cost Type "num-routingcost", the solicited ALTO Server has
defined 3 different daily patterns each represented by a Calendar, to
cover the week of Monday June 30th at 00:00 to Sunday July 6th 23:59:

- C1 for Monday, Tuesday, Wednesday, Thursday, (weekdays)
- C2 for Saturday, Sunday, (weekend)
- C3 for Friday (maintenance outage on July 4, 2014 from 02:00:00 GMT
to 04:00:00 GMT, or big holiday such as New Year evening).

In the following example, the ALTO Client sends its request on
Tuesday July 1st 2014 at 13:15.

The "routingcost" values are assumed to be encoded in 3 digits.

For representation brevity, the arrays in the provided example are
symbolized by expression "[v1,v2, ..., v24]", that is otherwise not
valid in JSON. The value of field "Content-Length" in the responses
is computed as if "routingcost" values were encoded in 3 digits.
POST /calendar/endpointcost/lookup HTTP/1.1
Host: alto.example.com
Content-Length: 290
Content-Type: application/alto-endpointcostparams+json
Accept: application/alto-endpointcost+json,application/alto-error+json

{
    "cost-type" : {
        "cost-mode" : "numerical",
        "cost-metric" : "routingcost"
    },
    "calendared" : [true],
    "endpoints" : {
        "srcs": [ "ipv4:192.0.2.2" ],
        "dsts": [ "ipv4:192.0.2.89",
            "ipv4:198.51.100.34",
            "ipv4:203.0.113.45",
            "ipv6:2001:db8::10"
        ]
    }
}

HTTP/1.1 200 OK
Content-Length: 877
Content-Type: application/alto-endpointcost+json

{
    "meta" : {
        "cost-type" : {
            "cost-mode" : "numerical",
            "cost-metric" : "routingcost"
        },
        "calendar-response-attributes" : [{
            "calendar-start-time" : "Mon, 30 Jun 2014 00:00:00 GMT",
            "time-interval-size" : 3600,
            "number-of-intervals" : 24,
            "repeated": 4
        }],
    },
    "endpoint-cost-map" : {
        "ipv4:192.0.2.2" : {
            "ipv4:192.0.2.89" : [v1, v2, ... v24],
            "ipv4:198.51.100.34" : [v1, v2, ... v24],
            "ipv4:203.0.113.45" : [v1, v2, ... v24],
            "ipv6:2001:db8::10" : [v1, v2, ... v24]
        }
    }
}
When the Client gets the Calendar for "routingcost", it sees that the "calendar-start-time" is Monday at 00h00 GMT and member "repeated" is equal to ‘4’. It understands that the provided values are valid until Thursday included and will only need to get a Calendar update on Friday.

4.2.4. Use case and example: ECS with a multi-cost Calendar for routingcost and owdelay

In this example, it is assumed that the ALTO Server implements multi-cost capabilities, as specified in [RFC8189]. That is, an ALTO client can request and receive values for several cost types in one single transaction. An illustrating use case is a path selection done on the basis of 2 metrics: routing cost and owdelay.

As in the previous example, the IRD indicates that the ALTO Server provides "routingcost" Calendars in terms of 24 time intervals of 1 hour (3600 seconds) each.

For metric "owdelay", the IRD indicates that the ALTO Server provides Calendars in terms of 12 time intervals values lasting each 5 minutes (300 seconds).

In the following example transaction, the ALTO Client sends its request on Tuesday July 1st 2014 at 13:15.

This example assumes that the values of metric "owdelay" and "routingcost" are encoded in 3 digits.

For representation brevity, the arrays in the provided example are symbolized by expression "[[r1, r2, ... r24], [o1, o2, ... o12]]", that is otherwise not valid in JSON. The value of field "Content-Length" in the responses is computed as if "routingcost" and "owdelay" values were encoded in 3 digits.

POST calendar/endpointcost/lookup HTTP/1.1
Host: alto.example.com
Content-Length: 373
Content-Type: application/alto-endpointcostparams+json
Accept: application/alto-endpointcost+json,application/alto-error+json

{  
"cost-type" : {},
"multi-cost-types" : [
  {"cost-mode" : "numerical", "cost-metric" : "routingcost"},
  {"cost-mode" : "numerical", "cost-metric" : "owdelay"}
],

"calendared" : [true, true],
"endpoints" : {
  "srcs": [ "ipv4:192.0.2.2" ],
  "dsts": [ 
    "ipv4:192.0.2.89",
    "ipv4:198.51.100.34",
    "ipv4:203.0.113.45",
    "ipv6:2001:db8::10"
  ]
}
}

HTTP/1.1 200 OK
Content-Length: 1377
Content-Type: application/alto-endpointcost+json
{
  "meta" : {
    "multi-cost-types" : [
      {"cost-mode" : "numerical", "cost-metric" : "routingcost"},
      {"cost-mode" : "numerical", "cost-metric" : "owdelay"}
    ],
    "calendar-response-attributes" : [
      {"cost-type-names" : "num-routingcost",
        "calendar-start-time" : "Mon, 30 Jun 2014 00:00:00 GMT",
        "time-interval-size" : 3600,
        "number-of-intervals" : 24,
        "repeated": 4 },
      {"cost-type-names" : "num-owdelay",
        "calendar-start-time" : "Tue, 1 Jul 2014 13:00:00 GMT",
        "time-interval-size" : 300,
        "number-of-intervals" : 12}
    ],
  },
  "endpoint-cost-map" : {
    "ipv4:192.0.2.2": {
      "ipv4:192.0.2.89" : [[r1, r2, ... r24], [o1, o2, ... o12]],
      "ipv4:198.51.100.34" : [[r1, r2, ... r24], [o1, o2, ... o12]],
      "ipv4:203.0.113.45" : [[r1, r2, ... r24], [o1, o2, ... o12]],
      "ipv6:2001:db8::10" : [[r1, r2, ... r24], [o1, o2, ... o12]]
    }
  }
}

When receiving the response, the client sees that the Calendar values for ‘routing cost’ are repeated for 4 iterations. Therefore, in its
next requests until the routing cost Calendar is expected to change, the client will only need to request a Calendar for "owdelay".

Without the ALTO Calendar extensions, the ALTO client would have no clue on the dynamicity of the metric value change and would spend needless time requesting values at an inappropriate pace. In addition, without the Multi-Cost ALTO capabilities, the ALTO client would duplicate this waste of time as it would need to send one request per cost metric.

5. IANA Considerations

This document does not define any new media types or introduce any new IANA considerations.

6. Security Considerations

As an extension of the base ALTO protocol [RFC7285], this document fits into the architecture of the base protocol, and hence the Security Considerations (Section 15) of the base protocol fully apply when this extension is provided by an ALTO server. For example, the same authenticity and integrity considerations (Section 15.1 of [RFC7285]) still fully apply; the same considerations for the privacy of ALTO users (Section 15.4 of [RFC7285]) also still fully apply.

The calendaring information provided by this extension requires additional considerations on three security considerations discussed in the base protocol: potential undesirable guidance to clients (Section 15.2 of [RFC7285]), confidentiality of ALTO information (Section 15.2 of [RFC7285]), and availability of ALTO (Section 15.5 of [RFC7285]). For example, by providing network information in the future in a Calendar, this extension may improve availability of ALTO, when the ALTO server is unavailable but related information is already provided in the Calendar.

For confidentiality of ALTO information, an operator should be cognizant that this extension may introduce a new risk: an ALTO client may get information for future events that are scheduled through Calendaring. Possessing such information, the client may use it to achieve its goal: (1) initiating connections only at advantageous network costs, leading to unexpected network load; (2) generating massive connections to the network at times where its load is expected to be high.

To mitigate this risk, the operator should address the risk of ALTO information being leaked to malicious clients or third parties. As specified in Section 15.3.2 ("Protection Strategies") of [RFC7285], the ALTO server should authenticate ALTO clients and use the
Transport Layer Security (TLS) protocol so that Man In The Middle (MITM) attacks to intercept an ALTO Calendar are not possible. [RFC7285] ensures the availability of such a solution in its Section 8.3.5. "Authentication and Encryption", which specifies that: "ALTO server implementations as well as ALTO client implementations MUST support the "https" URI scheme of [RFC2818] and Transport Layer Security (TLS) of [RFC5246]."

[RFC8446] specifies TLS 1.3 and writes in its section 1: "While TLS 1.3 is not directly compatible with previous versions, all versions of TLS incorporate a versioning mechanism which allows clients and servers to interoperably negotiate a common version if one is supported by both peers". So ALTO clients and servers MAY use newer versions (e.g., 1.3) of TLS as long as the negotiation process succeeds. To ensure backward compatibility with [RFC7285], it is RECOMMENDED for both Calendar-aware Clients and Servers to both support at least TLS 1.2, until it gets deprecated.

To avoid malicious or erroneous guidance from ALTO information, an ALTO client should be cognizant that using calendaring information can have risks: (1) Calendar values, especially in "repeated" Calendars may be only statistical, and (2) future events may change. Hence, a more robust ALTO client should adapt and extend protection strategies specified in Section 15.2 of the base protocol: it should develop self-check and also ensure information update, to reduce the impact of this risk. To address the risk of unexpected ALTO Values changes that the ALTO Client would be unaware of, it is RECOMMENDED that Servers supporting Calendars also support the "ALTO Incremental Updates Using Server-Sent Events (SSE)" Service, specified in [draft-ietf-alto-incr-update-sse]. Likewise, it is RECOMMENDED that Clients using Calendars also support the SSE Service.

7. Operational Considerations

Conveying ALTO Cost Calendars tends to reduce the on-the-wire data exchange volume compared to multiple single cost ALTO transactions. An application using Calendars has a set of time-dependent values upon which it can plan its connections in advance with no need for the ALTO Client to query information at each time. Additionally, the Calendar response attribute "repeated", when provided, saves additional data exchanges in that it indicates that the ALTO Client does not need to query Calendars during a period indicated by this attribute. Unexpected changes during this period can be handled by using the SSE Service as discussed in Section 6, if the Server and the Client support it.

High-resolution intervals may be needed when values change, sometimes during very small time intervals but in a significant manner. A way
to avoid conveying too many entries is to leverage on the "repeated" feature. A server can smartly set the Calendar start time and number of intervals so as to declare them "repeated" for a large number of periods, until the Calendar values change and are conveyed to requesting Clients.

Clients and Servers supporting ALTO Calendars use [RFC8259]. [RFC7285] encodes its requests and responses using the JSON Data Interchange Format specified in [RFC7159]. In the meantime, [RFC7159] has been obsoleted by [RFC8259], that among others makes UTF-8 mandatory for text encoding to improve interoperability. Therefore, ALTO Clients and Servers implementations using UTF-16,32 need to be cognizant of the subsequent interoperability risks and it is RECOMMENDED for them to switch to UTF-8 encoding, if they want to interoperate with Calendar-aware Servers and Clients.

8. Acknowledgements

The authors would like to thank Fred Baker, Li Geng, Diego Lopez, He Peng and Haibin Song for fruitful discussions and feedback on earlier draft versions. Dawn Chan, Kai Gao, Vijay Gurbani, Yichen Qian and Jensen Zhang provided substantial review feedback and suggestions to the protocol design.

ALTO Extension: Path Vector
draft-ietf-alto-path-vector-08

Abstract

This document defines an ALTO extension that allows a resource to provide not only preferences of network paths but also correlations of network paths, including aggregations of network components and their properties on the paths between different PIDs or endpoints. The extended information can be used to improve the robustness and performance for applications in some new usage scenarios, such as high-speed data transfers and traffic optimization using in-network storage and computation. This document introduces abstract network element (ANE) as an abstraction for aggregations of network components. It extends the base protocol and the Unified Property extension to enable the capability of encoding such information in a "path vector", i.e., an array of ANEs that are traversed by traffic from a source to a destination.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.
Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 23, 2020.

1. Introduction

The ALTO protocol is aimed to provide applications with knowledge of the underlying network topologies from the point of views of ISPs. The base protocol [RFC7285] defines cost maps and endpoint cost services that expose the preferences of network paths for a set of source and destination pairs.

While the preferences of network paths are already sufficient for a wide range of applications, new application traffic patterns and new network technologies are emerging that are well beyond the domain for which existing ALTO maps are engineered, including but not limited to:

Very-high-speed data transfers: Applications, such as Content Distribution Network (CDN) overlays, geo-distributed data centers and large-scale data analytics, are foundations of many Internet services today and have very large traffic between a source and a destination. Thus, the interference between traffic of different source and destination pairs cannot be omitted, which cannot be provided by or inferred from existing ALTO base protocol and extensions.

In-network storage and computation: Emerging networking technologies such as network function virtualization and mobile edge computing provide storage and computation inside the network. Applications can leverage these resources to further improve their performance, for example, using in-network caching to reduce latency and bandwidth from a given source to multiple clients. However, existing ALTO extensions provide no map resources to discover available in-network services, nor any information to help ALTO clients determine how to effectively and efficiently use these services.

This document specifies a new extension to incorporate these newly emerged scenarios into the ALTO framework. The essence of this extension is that an ALTO server exposes correlations of network paths in additional to preferences of network paths.

The correlations of network paths are represented by path vectors. Each element in a path vector, which is referred to as an abstract network element (ANE), is the aggregation of network components on the path, such as routers, switches, links and clusters of in-network servers. If an abstract network element appears in multiple network paths, the traffic along these paths will join at this abstract network element and are subject to the corresponding resource constraints.
The availability of the path correlations by itself can help ALTO clients conduct better traffic scheduling. For example, an ALTO client can use the path correlations to conduct more intelligent end-to-end measurement and identify traffic bottlenecks.

By augmenting these abstract network elements with different properties, an ALTO server can provide a more fine-grained view of the network. ALTO clients can use this view to derive information such as shared risk resource groups, capacity regions and available in-network cache locations, which can be used to improve the robustness and performance of the application traffic.

2. Terminology

This document extends the ALTO base protocol [RFC7285] and the Unified Property Map extension [I-D.ietf-alto-unified-props-new]. In addition to the ones defined in these documents, this document also uses the following additional terms:

- **Abstract network element (ANE):** An abstract network element is an abstraction of network components. It can be a link, a middleboxes, a virtualized network function (VNF), etc., or their aggregations. In a response, each abstract network element has a unique ANE identifier.

- **Path vector:** A path vector is an array of ANE identifiers. It presents an abstract network path between source/destination points such as PIDs or endpoints.

- **Path vector resource:** A path vector resource refers to an ALTO resource which supports the extension defined in this document.

- **Path vector response:** A path vector response refers to the multipart/related message returned by a path vector resource. It consists of a path vector part, i.e., the (endpoint) cost map part which contains the path vector information, and a property map part.

3. Use Cases

This section describes typical use cases of the path vector extension. These use cases provide new usage scenarios of the ALTO framework.
3.1. Shared Risk Resource Group

Consider an application which controls 4 end hosts (eh1, eh2, eh3 and eh4), which are connected by an ISP network with 5 switches (sw1, sw2, sw3, sw4 and sw5) and 5 links (l1, l2, l3, l4 and l5), as shown in Figure 1. Assume the end hosts are running data storage services and some analytics tasks, which requires high data availability. In order to determine the replica placement, the application must know how the end hosts will be partitioned if certain network failures happen.

For that purpose, the application uses an ALTO client, which communicates with an ALTO server provided by the ISP network. Since the Endpoint Cost Service with only scalar cost values cannot provide essential information for the application, thus, both the client and the server have the path vector extension enabled.

Assume the ISP uses shortest path routing. For simplicity, consider the data availability on eh4. The network components on the paths from all other end hosts to eh4 are as follows:

Figure 1: Topology for the Shared Risk Resource Group and the Capacity Region Use Cases
eh1→eh4: sw1, l1, sw3, l4, sw5
eh2→eh4: sw2, l2, sw3, l4, sw5
eh3→eh4: sw4, l5, sw5

These network components can be categorized into 5 categories:

1. Failure will only disconnect eh1 to eh4: sw1, l1.
2. Failure will only disconnect eh2 to eh4: sw2, l2.
3. Failure will only disconnect eh3 to eh4: sw4, l5.
4. Failure will only disconnect eh1 and eh2 to eh4: sw3, l4.
5. Failure will disconnect eh1, eh2 and eh3 to eh4: sw5.

The ALTO server can then aggregate sw1 and l1 as an abstract network element, ane1. By applying the aggregation to the categories, the response may be as follows:

eh1→eh4: ane1, ane4, ane5
eh2→eh4: ane2, ane4, ane5
eh3→eh4: ane3, ane5

Thus, the application can still derive the potential network partitions for all possible network failures without knowing the exact network topology, which protects the privacy of the ISP.

3.2. Capacity Region

This use case uses the same topology and application settings as in Section 3.1 as shown in Figure 1. Assume the capacity of each link is 10 Gbps, except l5 whose capacity is 5 Gbps. Assume the application is running a map-reduce task, where the optimal traffic scheduling is usually referred to the co-flow scheduling problem. Consider a simplified co-flow scheduling problem, e.g., the first stage of a map-reduce task which needs to transfer data from two data nodes (eh1 and eh3) to the mappers (eh2 and eh4). In order to optimize the job completion time, the application needs to determine the bottleneck of the transfers.

If the ALTO server encodes the routing cost as bandwidth of the path, the client will obtain the following information:

eh1→eh2: 10 Gbps,
eh1→eh4: 10 Gbps,
eh3→eh2: 10 Gbps,
eh3→eh4: 5 Gbps.
However, it does not provide sufficient information to determine the bottleneck. With the path vector extension, the ALTO server will first return the correlations of network paths between eh1, eh3 and eh2, eh4, as follows:

\[
\begin{align*}
\text{eh1} &\rightarrow \text{eh2}: \text{ane1} (11), \text{ane2} (12), \\
\text{eh1} &\rightarrow \text{eh4}: \text{ane1} (11), \text{ane4} (14), \\
\text{eh3} &\rightarrow \text{eh2}: \text{ane3} (13), \text{ane2} (12), \\
\text{eh3} &\rightarrow \text{eh3}: \text{ane5} (15).
\end{align*}
\]

Meanwhile, the ALTO server can also return the capacity of each ANE:

\[
\begin{align*}
\text{ane1}.\text{capacity} &= 10 \text{ Gbps}, \\
\text{ane2}.\text{capacity} &= 10 \text{ Gbps}, \\
\text{ane3}.\text{capacity} &= 10 \text{ Gbps}, \\
\text{ane4}.\text{capacity} &= 10 \text{ Gbps}, \\
\text{ane5}.\text{capacity} &= 5 \text{ Gbps}.
\end{align*}
\]

With the correlation of network paths and the link capacity property, the client is able to derive the capacity region of data transfer rates. Let \(x_1\) denote the transfer rate of eh1->eh2, \(x_2\) denote the rate of eh1->eh4, \(x_3\) denote the rate of eh3->eh2, and \(x_4\) denote the rate of eh3->eh4. The application can derive the following information from the responses:

<table>
<thead>
<tr>
<th></th>
<th>eh1-&gt;eh2</th>
<th>eh1-&gt;eh4</th>
<th>eh3-&gt;eh2</th>
<th>eh3-&gt;eh4</th>
<th>capacity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ane1</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>10 Gbps</td>
</tr>
<tr>
<td>ane2</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>10 Gbps</td>
</tr>
<tr>
<td>ane3</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>10 Gbps</td>
</tr>
<tr>
<td>ane4</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>10 Gbps</td>
</tr>
<tr>
<td>ane5</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>5 Gbps</td>
</tr>
</tbody>
</table>

Specifically, the coefficient matrix on the left hand side is the transposition of the matrix directly derived from the path vector part, and the right-hand-side vector is directly derived from the property map part. Thus, the bandwidth constraints of the data transfers are as follows:

\[
\begin{align*}
\text{x1 + x2} &\leq 10 \text{ Gbps (ane1)}, \\
\text{x1 + x3} &\leq 10 \text{ Gbps (ane2)}, \\
\text{x2 + x3} &\leq 10 \text{ Gbps (ane3)}, \\
\text{x2} &\leq 10 \text{ Gbps (ane4)}, \\
\text{x4} &\leq 5 \text{ Gbps (ane5)}.
\end{align*}
\]
3.3. In-Network Caching

Consider an application which controls 3 end hosts (eh1, eh2 and eh3), which are connected by an ISP network and the Internet, as shown in Figure 2. Assume two clients at end hosts eh2 and eh3 are downloading the same data from a data server at eh1. Meanwhile, the network provider offers an in-network caching service at the gateway.

With the path vector extension enabled, the ALTO server can expose two types of information

Without the traffic correlation information, the ALTO client cannot know whether or how the traffic goes through the proxy. For example, if subnet1 and subnet2 are directly connected and the traffic from eh1 to eh2 bypasses the gateway, the in-network cache can only be used for traffic from C2 to S and is less effective.

4. Overview

This section gives a top-down overview of approaches adopted by the path vector extension, with discussions to fully explore the design space. It is assumed that readers are familiar with both the base protocol [RFC7285] and the Unified Property Map extension [I-D.ietf-alto-unified-props-new].
4.1. Workflow

The workflow of the base ALTO protocol consists of one round of communication: An ALTO client sends a request to an ALTO server, and the ALTO server returns a response, as shown in Figure 3. Each response contains only one type of ALTO resources, e.g., network maps, cost maps, or property maps.

![Figure 3: Information Exchange Process of the base ALTO Protocol and the Path Vector Extension](image)

The path vector extension, on the other hand, can be decomposed to two types of information resources. First, path vectors, which represent the correlations of network paths for all <source, destination> pairs in the request, can be encoded as an (endpoint) cost map with an extended cost type. Second, properties associated with the ANEs can be encoded as a property map.

Instead of making two consecutive queries, however, the path vector extension adopts a workflow which also consists of only one round of communication, based on the following reasons:

1. ANE Computation Flexibility. For better scalability, flexibility and privacy, Abstract Network Elements MAY be constructed on demand, and potentially based on the properties (See Section 4.2 for more details). If sources and destinations are not in the
same request as the properties, an ALTO server either CANNOT construct ANEs on-demand, or MUST wait until both requests are received.

2. Server Scalability. As ANEs are constructed on demand, mappings of each ANE to its underlying network devices and resources CAN be different in different queries. In order to respond to the second request correctly, an ALTO server MUST store the mapping of each path vector request until the client fully retrieves the property information, which CAN substantially harm the server scalability and potentially lead to Denial-of-Service attacks.

Thus, the path vector extension encapsulates all essential information in one request, and returns both path vectors and properties associated with the ANEs in a single response. See Section 4.3 for more details.

4.2. Abstract Network Element

A key design in the path vector extension is abstract network element. Abstract network elements can be statically generated, for example, based on geo-locations, OSPF areas, or simply the raw network topology. They CAN also be generated dynamically, based on a client’s request. This on-demand ANE generation allows for better scalability, flexibility and privacy enhancement.

Consider an extreme case where the client only queries the bandwidth between one source and one destination in the topology shown in Figure 4. Without knowing in prior the desired property, an ALTO server MAY need to include all network components on the paths for high accuracy. However, with the prior knowledge that the client only asks for the bandwidth information, an ALTO server CAN either 1) selectively pick the link with the smallest available bandwidth, or 2) dynamically generate a new ANE whose available bandwidth is the smallest value of the links’ on the path. Thus, an ALTO server can provide accurate information with very little leak of its internal network topology. ANEs MAY also be constructed based on algebraic aggregations, please see [TON2019] for more details.

![Figure 4: Topology for Dynamic ANE Example.](image)

An ANE is uniquely identified by an ANE identifier (see Section 5.1) in the same response. However, since ANEs CAN be generated dynamically, an ALTO client MUST NOT assume that ANEs with the same
identifier but from different queries refer to the same aggregation of network components. This approach simplifies the management of ANE identifiers at ALTO servers, and increases the difficulty to infer the real network topology with cross queries. It is RECOMMENDED that the identifiers of statically generated ANEs be anonymized in the path vector response, for example, by shuffling the ANEs and shrinking their identifier space to \([1, N]\), where \(N\) is the number of ANEs etc.

4.3. Protocol Extensions

Section 4.1 has well articulated the reasons to complete the information exchange in a single round of communication. This section introduces the three major extended components to the base ALTO protocol and the Unified Property Map extension, as shown in Table 1.

<table>

</tbody>
</table>

Table 1: Extended Components and Where They Apply.

4.3.1. Path Vector Cost Type

Existing cost modes defined in [RFC7285] allow only scalar cost values. However, the path vector extension MUST convey vector format information. To fulfill this requirement, this document defines a new cost mode named "array", which indicates that the cost value MUST be interpreted as an array of JSONValue. This document also introduces a new cost metric "ane-path" to convey an array of ANE identifiers.

The combination of the "array" cost mode and the "ane-path" cost metric also complies best with the ALTO base protocol, where cost mode specifies the interpretation of a cost value, and cost metric conveys the meaning.

4.3.2. Property Negotiation

Similar to cost types, an ALTO server MAY only support a given set of ANE properties in a path vector information resource. Meanwhile, an ALTO client MAY only require a subset of the available properties. Thus, a property negotiation process is required.
This document uses a similar approach as the negotiation process of cost types: the available properties for a given resource are announced in the Information Resource Directory and more specifically, in a new capability called "ane-properties"; the selected properties SHOULD be specified in a new filter called "ane-properties" in the request body; the response MUST return and only return the selected properties for the ANEs in the response, if applicable.

4.3.3. Multipart/Related Message

Path vectors and the property map containing the ANEs are two different types of objects, but they need to be encoded in one message. One approach is to define a new media type to contain both objects, but this violates modular design.

This document uses standard-conforming usage of "multipart/related" media type defined in [RFC2387] to elegantly combine the objects. Path vectors are encoded as a cost map or an endpoint cost map, and the property map is encoded as a Unified Propert Map. They are encapsulated as parts of a multipart message. The modular composition allows ALTO servers and clients to reuse the data models of the existing information resources. Specifically, this document addresses the following practical issues using "multipart/related".

4.3.3.1. Identifying the Media Type of the Root Object

ALTO uses media type to indicate the type of an entry in the Information Resource Directory (IRD) (e.g., "application/alto-costmap+json" for cost map and "application/alto-endpointcost+json" for endpoint cost map). Simply putting "multipart/related" as the media type, however, makes it impossible for an ALTO client to identify the type of service provided by related entries.

To address this issue, this document uses the "type" parameter to indicate the root object of a multipart/related message. For a cost map resource, the "media-type" in the IRD entry MUST be "multipart/related" with the parameter "type=application/alto-costmap+json"; for an Endpoint Cost Service, the parameter MUST be "type=application/alto-endpointcost+json".

4.3.3.2. References to Part Messages

The ALTO SSE extension (see [I-D.ietf-alto-incr-update-sse]) uses "client-id" to demultiplex push updates. However, "client-id" is provided for each request, which introduces ambiguity when applying SSE to a path vector resource.
To address this issue, an ALTO server MUST assign a unique identifier to each part of the "multipart/related" response message. This identifier, referred to as a Part Resource ID (See Section 5.6 for details), MUST be present in the part message’s "Resource-Id" header. The MIME part header MUST also contain the "Content-Type" header, whose value is the media type of the part (e.g., "application/alto-costmap+json", "application/alto-endpointcost+json", or "application/alto-propmap+json").

If an ALTO server provides incremental updates for this path vector resource, it MUST generate incremental updates for each part separately. The client-id MUST have the following format:

```
pv-client-id '.' part-resource-id
```

where pv-client-id is the client-id assigned to the path vector request, and part-resource-id is the "Resource-Id" header value of the part. The media-type MUST match the "Content-Type" of the part.

The same problem happens inside the part messages as well. The two parts MUST contain a version tag, which SHOULD contain a unique Resource ID. This document requires the resource-id in a Version Tag to have the following format:

```
pv-resource-id '.' part-resource-id
```

where pv-resource-id is the resource ID of the path vector resource in the IRD entry, and the part-resource-id has the same value as the "Resource-Id" header of the part.

4.3.3.3. Order of Part Messages

According to RFC 2387 [RFC2387], the path vector part, whose media type is the same as the "type" parameter of the multipart response message, is the root object. Thus, it is the element the application processes first. Even though the "start" parameter allows it to be placed anywhere in the part sequence, it is RECOMMENDED that the parts arrive in the same order as they are processed, i.e., the path vector part is always put as the first part, followed by the property map part. It is also RECOMMENDED that when doing so, an ALTO server SHOULD NOT set the "start" parameter, which implies the first part is the root object.

5. Basic Data Types
5.1. ANE Identifier

An ANE identifier is encoded as a JSON string. The string MUST be no more than 64 characters, and it MUST NOT contain characters other than US-ASCII alphanumeric characters (U+0030-U+0039, U+0041-U+005A, and U+0061-U+007A), the hyphen ("-", U+002D), the colon (":", U+003A), the at sign (@", code point U+0040), the low line ("_", U+005F), or the "." separator (U+002E). The "." separator is reserved for future use and MUST NOT be used unless specifically indicated in this document, or an extension document.

The type ANEIdentifier is used in this document to indicate a string of this format.

5.2. Path Vector Cost Type

This document defines a new cost type, which is referred to as the "path vector" cost type. An ALTO server MUST offer this cost type if it supports the path vector extension.

5.2.1. Cost Metric: ane-path

This cost metric conveys an array of ANE identifiers, where each identifier uniquely represents an ANE traversed by traffic from a source to a destination.

5.2.2. Cost Mode: array

This cost mode indicates that every cost value in a cost map or an endpoint cost map MUST be interpreted as a JSON array object.

Note that this cost mode only requires the cost value to be a JSON array of JSONValue. However, an ALTO server that enables this extension MUST return a JSON array of ANEIdentifier (Section 5.1) when the cost metric is "ane-path".

5.3. ANE Domain

This document specifies a new ALTO entity domain called "ane" in addition to the ones in [I-D.ietf-alto-unified-props-new]. The ANE domain associates property values with the ANEs in a network. The entity in ANE domain is often used in the path vector by cost maps or endpoint cost resources. Accordingly, the ANE domain always depends on a cost map or an endpoint cost map.
5.3.1. Entity Domain Type

ane

5.3.2. Domain-Specific Entity Identifier

The entity identifier of ANE domain uses the same encoding as ANEIdentifier (Section 5.1).

5.3.3. Hierarchy and Inheritance

There is no hierarchy or inheritance for properties associated with ANEs.

5.4. New Resource-Specific Entity Domain Exports

5.4.1. ANE Domain of Cost Map Resource

If an ALTO cost map resource supports "ane-path" cost metric, it can export an "ane" typed entity domain defined by the union of all sets of ANE names, where each set of ANE names are an "ane-path" metric cost value in this ALTO cost map resource.

5.4.2. ANE Domain of Endpoint Cost Resource

If an ALTO endpoint cost resource supports "ane-path" cost metric, it can export an "ane" typed entity domain defined by the union of all sets of ANE names, where each set of ANE names are an "ane-path" metric cost value in this ALTO endpoint cost resource.

5.5. ANE Properties

5.5.1. ANE Property: Maximum Reservable Bandwidth

The maximum reservable bandwidth property conveys the maximum bandwidth that can be reserved for traffic from a source to a destination and is indicated by the property name "maxresbw". The value MUST be encoded as a numerical cost value as defined in Section 6.1.2.1 of [RFC7285] and the unit is bit per second.

If this property is requested but is missing for a given ANE, it MUST be interpreted as that the ANE does not support bandwidth reservation but have sufficiently large bandwidth for all traffic that traverses it.
5.5.2. ANE Property: Persistent Entity

The persistent entity property conveys the physical or logical network entities (e.g., links, in-network caching service) that are contained by an abstract network element. It is indicated by the property name "persistent-entity". The value is encoded as a JSON array of entity identifiers ([I-D.ietf-alto-unified-props-new]). These entity identifiers are persistent so that a client CAN further query their properties for future use.

If this property is requested but is missing for a given ANE, it MUST be interpreted as that no such entities exist in this ANE.

5.6. Part Resource ID

A Part Resource ID is encoded as a JSON string with the same format as that of the Resource ID (Section 10.2 of [RFC7285]).

WARNING: Even though the client-id assigned to a path vector request and the Part Resource ID MAY contain up to 64 characters by their own definition. Their concatenation (see Section 4.3.3.2) MUST also conform to the same length constraint. The same requirement applies to the resource ID of the path vector resource, too. Thus, it is RECOMMENDED to limit the length of resource ID and client ID related to a path vector resource to 31 characters.

6. Service Extensions

6.1. Multipart Filtered Cost Map for Path Vector

This document introduces a new ALTO resource called multipart filtered cost map resource, which allows an ALTO server to provide other ALTO resources associated to the cost map resource in the same response.

6.1.1. Media Type

The media type of the multipart filtered cost map resource is "multipart/related;type=application/alto-costmap+json".

6.1.2. HTTP Method

The multipart filtered cost map is requested using the HTTP POST method.
6.1.3. Accept Input Parameters

The input parameters of the multipart filtered cost map are supplied in the body of an HTTP POST request. This document extends the input parameters to a filtered cost map with a data format indicated by the media type "application/alto-costmapfilter+json", which is a JSON object of type PVReqFilteredCostMap, where:

```json
object {
  [PropertyName ane-properties<0..*>;]
} PVReqFilteredCostMap : ReqFilteredCostMap;
```

with fields:

- **ane-properties**: A list of properties that are associated with the ANEs. Each property in this list MUST match one of the supported ANE properties indicated in the resource’s "ane-properties" capability. If the field is NOT present, it MUST be interpreted as an empty list, indicating that the ALTO server MUST NOT return any property in the unified property part.

6.1.4. Capabilities

The multipart filtered cost map resource extends the capabilities defined in Section 11.3.2.4 of [RFC7285]. The capabilities are defined by a JSON object of type PVFilteredCostMapCapabilities:

```json
object {
  [PropertyName ane-properties<0..*>;]
} PVFilteredCostMapCapabilities : FilteredCostMapCapabilities;
```

with fields:

- **cost-type-names**: The "cost-type-names" field MUST only include the path vector cost type, unless explicitly documented by a future extension. This also implies that the path vector cost type MUST be defined in the "cost-types" of the Information Resource Directory’s "meta" field.

- **ane-properties**: Defines a list of ANE properties that can be returned. If the field is NOT present, it MUST be interpreted as an empty list, indicating the ALTO server CANNOT provide any ANE property.
6.1.5. Uses

The resource ID of the network map based on which the PIDs in the returned cost map will be defined. If this resource supports "persistent-entities", it MUST also include ALL the resources that exposes the entities that MAY appear in the response.

6.1.6. Response

The response MUST indicate an error, using ALTO protocol error handling, as defined in Section 8.5 of [RFC7285], if the request is invalid.

The "Content-Type" header of the response MUST be "multipart/related" as defined by [RFC2387] with the following parameters:

type: The type parameter MUST be "application/alto-costmap+json".  
Note that [RFC2387] permits both parameters with and without the double quotes.

start: The start parameter MUST be a quoted string where the quoted part has the same value as the "Resource-ID" header in the first part.

boundary: The boundary parameter is as defined in [RFC2387].

The body of the response consists of two parts.

The first part MUST include "Resource-Id" and "Content-Type" in its header. The value of "Resource-Id" MUST has the format of a Part Resource ID. The "Content-Type" MUST be "application/alto-costmap+json".

The body of the first part MUST be a JSON object with the same format as defined in Section 11.2.3.6 of [RFC7285]. The JSON object MUST include the "vtag" field in the "meta" field, which provides the version tag of the returned cost map. The resource ID of the version tag MUST follow the format in Section 4.3.3.2. The "meta" field MUST also include the "dependent-vtags" field, whose value is a single-element array to indicate the version tag of the network map used, where the network map is specified in the "uses" attribute of the multipart filtered cost map resource in IRD.

The second part MUST also include "Resource-Id" and "Content-Type" in its header. The value of "Resource-Id" has the format of a Part Resource ID. The "Content-Type" MUST be "application/alto-propmap+json".
The body of the second part MUST be a JSON object with the same format as defined in Section 4.6 of [I-D.ietf-alto-unified-props-new]. The JSON object MUST include the "dependent-vtags" field in the "meta" field. The value of the "dependent-vtags" field MUST be an array of VersionTag objects as defined by Section 10.3 of [RFC7285]. The "vtag" of the first part MUST be included in the "dependent-vtags". If "persistent-entities" is requested, the version tags of the dependent resources that MAY expose the entities in the response MUST also be included. The PropertyMapData has one member for each ANE identifier that appears in the first part, where the EntityProps has one member for each property requested by the client if applicable.

6.2. Multipart Endpoint Cost Service for Path Vector

This document introduces a new ALTO resource called multipart endpoint cost resource, which allows an ALTO server to provide other ALTO resources associated to the endpoint cost resource in the same response.

6.2.1. Media Type

The media type of the multipart endpoint cost resource is "multipart/related;type=application/alto-endpointcost+json".

6.2.2. HTTP Method

The multipart endpoint cost resource is requested using the HTTP POST method.

6.2.3. Accept Input Parameters

The input parameters of the multipart endpoint cost resource are supplied in the body of an HTTP POST request. This document extends the input parameters to an endpoint cost map with a data format indicated by the media type "application/alto-endpointcostparams+json", which is a JSON object of type PVEndpointCostParams, where

object {
    [PropertyName ane-properties<0..*>;]
} PVReqEndpointcost : ReqEndpointcost;

with fields:

ane-properties: This document defines the "ane-properties" in PVReqEndpointcost as the same as in PVReqFilteredCostMap. See Section 6.1.3.
6.2.4. Capabilities

The capabilities of the multipart endpoint cost resource are defined by a JSON object of type PVEndpointCostCapabilities, which is defined as the same as PVFilteredCostMapCapabilities. See Section 6.1.4.

6.2.5. Uses

If a multipart endpoint cost resource supports "persistent-entities", the "uses" field in its IRD entry MUST include ALL the resources which exposes the entities that MAY appear in the response.

6.2.6. Response

The response MUST indicate an error, using ALTO protocol error handling, as defined in Section 8.5 of [RFC7285], if the request is invalid.

The "Content-Type" header of the response MUST be "multipart/related" as defined by [RFC2387] with the following parameters:

type: The type parameter MUST be "application/alto-endpointcost+json".

start: The start parameter MUST be a quoted string where the quoted part has the same value as the "Resource-ID" header in the first part.

boundary: The boundary parameter is as defined in [RFC2387].

The body consists of two parts:

The first part MUST include "Resource-Id" and "Content-Type" in its header. The value of "Resource-Id" MUST has the format of a Part Resource ID. The "Content-Type" MUST be "application/alto-endpointcost+json".

The body of the first part MUST be a JSON object with the same format as defined in Section 11.5.1.6 of [RFC7285]. The JSON object MUST include the "vtag" field in the "meta" field, which provides the version tag of the returned endpoint cost map. The resource ID of the version tag MUST follow the format in Section 4.3.3.2.

The second part MUST also include "Resource-Id" and "Content-Type" in its header. The value of "Resource-Id" MUST has the format of a Part Resource ID. The "Content-Type" MUST be "application/alto-propmap+json".
The body of the second part MUST be a JSON object with the same format as defined in Section 4.6 of [I-D.ietf-alto-unified-props-new]. The JSON object MUST include the "dependent-vtags" field in the "meta" field. The value of the "dependent-vtags" field MUST be an array of VersionTag objects as defined by Section 10.3 of [RFC7285]. The "vtag" of the first part MUST be included in the "dependent-vtags". If "persistent-entities" is requested, the version tags of the dependent resources that MAY expose the entities in the response MUST also be included. The PropertyMapData has one member for each ANE identifier that appears in the first part, where the EntityProps has one member for each property requested by the client if applicable.

7. Examples

This section lists some examples of path vector queries and the corresponding responses. Some long lines are truncated for better readability.

Below is an example of an Information Resource Directory which enables the path vector extension. Some critical modifications include:

- The "path-vector" cost type (Section 5.2) is defined in the "cost-types" of the "meta" field.
- The "cost-map-pv" information resource provides a multipart filtered cost map resource, which exposes the Maximum Reservable Bandwidth ("maxresbw") property.
- The "http-proxy-props" information resource provides a filtered unified property map resource, which exposes the HTTP proxy entity domain (encoded as "http-proxy") and the "price" property. Note that HTTP proxy is NOT a valid entity domain yet and is used here only for demonstration.
- The "endpoint-cost-pv" information resource provides a multipart endpoint cost resource. It exposes the Maximum Reservable Bandwidth ("maxresbw") property and the Persistent Entity property ("persistent-entities"). The persistent entities MAY come from the "http-proxy-props" resource.
- The "update-pv" information resource provides the incremental update ([I-D.ietf-alto-incre-update-sse]) service for the "endpoint-cost-pv" resource.

7.2. Example: Multipart Filtered Cost Map

The following examples demonstrate the request to the "cost-map-pv" resource and the corresponding response.

The request uses the path vector cost type in the "cost-type" field. The "ane-properties" field is missing, indicating that the client only requests for the path vector but not the ANE properties.

The response consists of two parts. The first part returns the array of ANE identifiers for each source and destination pair. There are three ANEs, where "ane:L001" is shared by traffic from "PID1" to both "PID2" and "PID3".

The second part returns an empty property map. Note that the ANE entries are omitted since they have no properties (See Section 3.1 of [I-D.ietf-alto-unified-props-new]).

POST /costmap/pv HTTP/1.1
Host: alto.example.com
Accept: multipart/related;type=application/alto-costmap+json,
        application/alto-error+json
Content-Length: [TBD]
Content-Type: application/alto-costmapfilter+json

{
    "cost-type": {
        "cost-mode": "array",
        "cost-metric": "ane-path"
    },
    "pids": {
        "srcs": [ "PID1" ],
        "dsts": [ "PID2", "PID3" ]
    }
}

HTTP/1.1 200 OK
Content-Length: [TBD]
Content-Type: multipart/related; boundary=example-1;
    type=application/alto-costmap+json

--example-1
Resource-Id: costmap
Content-Type: application/alto-costmap+json

{
    "meta": {

            }
        ],
        "property-map": {}
    }
}
7.3. Example: Multipart Endpoint Cost Resource

The following examples demonstrate the request to the "endpoint-cost-pv" resource and the corresponding response.

The request uses the path vector cost type in the "cost-type" field, and queries the Maximum Reservable Bandwidth ANE property and the Persistent Entity property.

The response consists of two parts. The first part returns the array of ANE identifiers for each valid source and destination pair.

The second part returns the requested properties of ANEs in the first part. The "ane:NET001" element contains an HTTP proxy entity, which can be further used by the client. Since it does not contain a "maxresbw" property, the client SHOULD assume it does NOT support bandwidth reservation but will NOT become a traffic bottleneck, as specified in Section 5.5.1.

POST /endpointcost/pv HTTP/1.1  
Host: alto.example.com  
Accept: multipart/related;  
type=application/alto-endpointcost+json,  
application/alto-error+json  
Content-Length: [TBD]  
Content-Type: application/alto-endpointcostparams+json

`{  
   "cost-type": {  
      "cost-mode": "array",  
      "cost-metric": "ane-path"  
   },  
   "endpoints": {  
      "srcs": [ "ipv4:192.0.2.2" ],  
      "dsts": [ "ipv4:192.0.2.89",  
                "ipv4:203.0.113.45",  
                "ipv6:2001:db8::10" ]  
   },  
   "ane-properties": [ "maxresbw", "persistent-entities" ]  
}`

HTTP/1.1 200 OK  
Content-Length: [TBD]  
Content-Type: multipart/related; boundary=example-2;  
type=application/alto-endpointcost+json

--example-2  
Resource-Id: ecs
Content-Type: application/alto-endpointcost+json

```
{
  "meta": {
    "vtags": {
      "resource-id": "endpoint-cost-pv.ecs",
      "tag": "bb6bb72eafe8f9bdc4f335c7ed3b10822a391cef"
    },
    "cost-type": {
      "cost-mode": "array",
      "cost-metric": "ane-path"
    }
  },
  "endpoint-cost-map": {
    "ipv4:192.0.2.2": {
      "ipv4:192.0.2.89": [ "ane:NET001", "ane:L002" ],
      "ipv4:203.0.113.45": [ "ane:NET001", "ane:L003" ]
    }
  }
}
--example-2
```

Resource-Id: propmap
Content-Type: application/alto-propmap+json

```
{
  "meta": {
    "dependent-vtags": [
      {
        "resource-id": "endpoint-cost-pv.ecs",
        "tag": "bb6bb72eafe8f9bdc4f335c7ed3b10822a391cef"
      },
      {
        "resource-id": "http-proxy-props",
        "tag": "bf3c8c1819d2421c9a95a9d02af557a3"
      }
    ]
  },
  "property-map": {
    "ane:NET001": {
      "persistent-entities": [ "http-proxy:192.0.2.1" ]
    },
    "ane:L002": { "maxresbw": 48000000 },
    "ane:L003": { "maxresbw": 35000000 }
  }
}
```
In this example, an ALTO client subscribes to the incremental update for the multipart endpoint cost resource "endpoint-cost-pv".

POST /updates/pv HTTP/1.1
Host: alto.example.com
Accept: text/event-stream
Content-Type: application/alto-updatestreamparams+json
Content-Length: [TBD]

{  "add": {  "ecspvsub1": {  "resource-id": "endpoint-cost-pv",  "input": <ecs-input>  }  }
}

Based on the server-side process defined in [I-D.ietf-alto-incr-update-sse], the ALTO server will send the "control-uri" first using Server-Sent Event (SSE), followed by the full response of the multipart message.

HTTP/1.1 200 OK
Connection: keep-alive
Content-Type: text/event-stream

event: application/alto-updatestreamcontrol+json
data: {"control-uri": "http://alto.example.com/updates/streams/1414"}

event: multipart/related;boundary=example-3;
type=application/alto-endpointcost+json,ecspvsub1
data: --example-3
data: Resource-ID: ecsmap
data: Content-Type: application/alto-endpointcost+json
data: <endpoint-cost-map-entry>
data: --example-3
data: Resource-ID: propmap
data: Content-Type: application/alto-propmap+json
data: <property-map-entry>
data: --example-3--

When the contents change, the ALTO server will publish the updates for each node in this tree separately.
8. Compatibility

8.1. Compatibility with Legacy ALTO Clients/Servers

The multipart filtered cost map resource and the multipart endpoint cost resource has no backward compatibility issue with legacy ALTO clients and servers. Although these two types of resources reuse the media types defined in the base ALTO protocol for the accept input parameters, they have different media types for responses. If the ALTO server provides these two types of resources, but the ALTO client does not support them, the ALTO client will ignore the resources without conducting any incompatibility.

8.2. Compatibility with Multi-Cost Extension

This document does not specify how to integrate the "path-vector" cost mode with the multi-cost extension [RFC8189]. Although there is no reason why somebody has to compound the path vectors with other cost types in a single query, there is no compatible issue doing it without constraint tests.

8.3. Compatibility with Incremental Update

The extension specified in this document is NOT compatible with the original incremental update extension [I-D.ietf-alto-incr-update-sse]. A legacy ALTO client CANNOT recognize the compound client-id, and a legacy ALTO server MAY use the same client-id for updates of both parts.

ALTO clients and servers MUST follow the specifications given in this document to ensure compatibility with the incremental update extension.

8.4. Compatibility with Cost Calendar

The extension specified in this document is compatible with the Cost Calendar extension [I-D.ietf-alto-cost-calendar]. When used together with the Cost Calendar extension, the cost value between a source and a destination is an array of path vectors, where the k-th path vector refers to the abstract network paths traversed in the k-th time interval by traffic from the source to the destination.
When used with time-varying properties, e.g., maximum reservable bandwidth (maxresbw), a property of a single entity may also have different values in different time intervals. In this case, an ANE with different property values MUST be considered as different ANEs.

The two extensions combined together CAN provide the historical network correlation information for a set of source and destination pairs. A network broker or client MAY use this information to derive other resource requirements such as Time-Block-Maximum Bandwidth, Bandwidth-Sliding-Window, and Time-Bandwidth-Product (TBP) (See [SENSE] for details.)

9. General Discussions

9.1. Provide Calendar for Property Map

Fetching the historical network information is useful for many traffic optimization problems. [I-D.ietf-alto-cost-calendar] already proposes an ALTO extension called Cost Calendar which provides the historical cost values using filtered cost map and endpoint cost service. However, the calendar for only path costs is not enough.

For example, as the properties of ANEs (e.g., available bandwidth and link delay) are usually the real-time network states, they change frequently in the real network. It is very helpful to get the historical value of these properties. Applications may predicate the network status using these information to better optimize their performance.

So the coming requirement may be a general calendar service for the ALTO information resources.

9.2. Constraint Tests for General Cost Types

The constraint test is a simple approach to query the data. It allows users to filter the query result by specifying some boolean tests. This approach is already used in the ALTO protocol. [RFC7285] and [RFC8189] allow ALTO clients to specify the "constraints" and "or-constraints" tests to better filter the result.

However, the current defined syntax is too simple and can only be used to test the scalar cost value. For more complex cost types, like the "array" mode defined in this document, it does not work well. It will be helpful to propose more general constraint tests to better perform the query.

In practice, it is too complex to customize a language for the general-purpose boolean tests, and can be a duplicated work. So it
may be a good idea to integrate some already defined and widely used query languages (or their subset) to solve this problem. The candidates can be XQuery and JSONiq.

9.3. General Multipart Resources Query

Querying multiple ALTO information resources continuously MAY be a general requirement. And the coming issues like inefficiency and inconsistency are also general. There is no standard solving these issues yet. So we need some approach to make the ALTO client request the compound ALTO information resources in a single query.

10. Security Considerations

This document is an extension of the base ALTO protocol, so the Security Considerations [RFC7285] of the base ALTO protocol fully apply when this extension is provided by an ALTO server.

The path vector extension requires additional considerations on two security considerations discussed in the base protocol: confidentiality of ALTO information (Section 15.3 of [RFC7285]) and availability of ALTO service (Section 15.5 of [RFC7285]).

For confidentiality of ALTO information, a network operator should be aware of that this extension may introduce a new risk: the path vector information may make network attacks easier. For example, as the path vector information may reveal more network internal structures than the base protocol, an ALTO client may detect the bottleneck link and start a distributed denial-of-service (DDoS) attack involving minimal flows to conduct the in-network congestion.

To mitigate this risk, the ALTO server should consider protection mechanisms to reduce information exposure or obfuscate the real information, in particular, in settings where the network and the application do not belong to the same trust domain. But the implementation of path vector extension involving reduction or obfuscation should guarantees the constraints on the requested properties are still accurate.

For availability of ALTO service, an ALTO server should be cognizant that using path vector extension might have a new risk: frequent requesting for path vectors might conduct intolerable increment of the server-side storage and break the ALTO server. It is known that the computation of path vectors is unlikely to be cacheable, in that the results will depend on the particular requests (e.g., where the flows are distributed). Hence, the service providing path vectors may become an entry point for denial-of-service attacks on the
availability of an ALTO server. To avoid this risk, authenticity and authorization of this ALTO service may need to be better protected.

11. IANA Considerations

11.1. ALTO Cost Mode Registry

This document specifies a new cost mode "path-vector". However, the base ALTO protocol does not have a Cost Mode Registry where new cost mode can be registered. This new cost mode will be registered once the registry is defined either in a revised version of [RFC7285] or in another future extension.

11.2. ALTO Entity Domain Registry

As proposed in Section 9.2 of [I-D.ietf-alto-unified-props-new], "ALTO Domain Entity Registry" is requested. Besides, a new domain is to be registered, listed in Table 2.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Entity Address Encoding</th>
<th>Hierarchy &amp; Inheritance</th>
</tr>
</thead>
<tbody>
<tr>
<td>ane</td>
<td>See Section 5.3.2</td>
<td>None</td>
</tr>
</tbody>
</table>

Table 2: ALTO Entity Domain

11.3. ALTO Entity Property Type Registry

The "ALTO Entity Property Type Registry" is required by the ALTO Domain "ane", listed in Table 3.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Intended Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>ane:maxresbw</td>
<td>The maximum reservable bandwidth for the ANE</td>
</tr>
<tr>
<td>ane:persistent-entities</td>
<td>An array of identifiers of persistent entities that reside in an ANE</td>
</tr>
</tbody>
</table>

Table 3: ALTO Entity Property Types

11.4. ALTO Resource Entity Domain Export Registries
11.4.1. costmap

<table>
<thead>
<tr>
<th>Entity Domain Type</th>
<th>Export Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>ane</td>
<td>See Section 5.4.1</td>
</tr>
</tbody>
</table>

Table 4: ALTO Cost Map Entity Domain Export.

11.4.2. endpointcost

<table>
<thead>
<tr>
<th>Entity Domain Type</th>
<th>Export Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>ane</td>
<td>See Section 5.4.2</td>
</tr>
</tbody>
</table>

Table 5: ALTO Endpoint Cost Entity Domain Export.

ALTO Performance Cost Metrics
draft-ietf-alto-performance-metrics-07

Abstract

Cost metric is a basic concept in Application-Layer Traffic Optimization (ALTO), and is used in basic services including both the cost map service and the endpoint cost service.

Different applications may use different cost metrics, but the ALTO base protocol documents only one single cost metric, i.e., the generic "routingcost" metric; see Sec. 14.2 of ALTO base specification [RFC7285]. Hence, if the resource consumer of an application prefers a resource provider that offers low-delay delivery to the resource consumer, the base protocol does not define the cost metric to be used.

ALTO cost metrics can be generic metrics and this document focuses on network performance metrics, including network delay, jitter, packet loss, hop count, and bandwidth. These metrics can be derived and aggregated from routing protocols with different granularity and scope, such as BGP-LS, OSPF-TE and ISIS-TE, or from end-to-end traffic management tools. These metrics may then be exposed by an ALTO Server to allow applications to determine "where" to connect based on network performance criteria. Additional cost metrics may be documented in other documents.

Requirements Language The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

1. Introduction

Cost Metric is a basic concept in Application-Layer Traffic Optimization (ALTO). It is used in both the ALTO cost map service and the ALTO endpoint cost service, to allow applications to request network cost metrics.

Different applications may use different cost metrics. Hence, the ALTO base protocol [RFC7285] introduces an ALTO Cost Metric Registry (Section 14.2 of [RFC7285]) as a systematic mechanism to allow different metrics to be specified. For example, a more delay-sensitive application may want to use latency related metrics, and a more bandwidth-sensitive application may want to use bandwidth related metrics. The ALTO base protocol [RFC7285], however, has...
registered only one single cost metric, i.e., the generic "routingcost" metric; no latency or bandwidth related metrics are defined.

This document registers a set of new cost metrics specified in Table 1, to support the aforementioned applications, to allow them to determine "where" to connect based on network performance criteria. This document follows the guideline (Section 14.2 of [RFC7285]) of the ALTO base protocol on registering ALTO cost metrics. Hence it specifies the identifier, the intended semantics, and the security considerations of each one of the metrics defined in Table 1.

Table 1. Cost Metrics Defined in this Document

The purpose of this document is to ensure proper usage of the metrics by ALTO clients. It does not claim novelty of the metrics. Some of these metrics are already specified by standards such as IPPM; some are ISP dependent such as those registered in ISIS or OSPF-TE. This document will refer to the relevant specifications.

An ALTO server may provide only a subset of the cost metrics described in this document. Hence, all cost metrics defined in this document are optional and not all them need to be exposed to applications. For example, those that are subject to privacy concerns should not be provided to unauthorized ALTO clients.

When an ALTO server supports a cost metric defined in this document, it MUST announce this metric in its information resource directory (IRD).

The cost metrics defined in this document can be retrieved and aggregated from routing protocols or other traffic measurement management tools, with corresponding operational issues. A potential architecture on computing these metrics is shown in Figure 1 below.

In Section 4, we discuss in more detail the operations issues and how to address them.
Figure 1. Potential framework to compute performance cost metrics

An ALTO server introducing these metrics should also consider security issues. As a generic security consideration on the reliability and trust in the exposed metric values, applications SHOULD rapidly give up using ALTO-based guidance if they feel the exposed information does not preserve their performance level or even degrades it. We discuss security considerations in more details in Section 5.

Following the ALTO base protocol, this document uses JSON to specify the value type of each defined metric. See [RFC4627] for JSON data type specification.

2. Network Performance Cost Metrics

This section introduces generic ALTO network performance metrics such as one way delay, round trip delay, hop count, packet loss, throughput derived and aggregated from routing protocols or from end to end traffic management tools.

2.1. Cost Metric: One Way Delay (owdelay)

Metric name:

One Way Delay
Metric Identifier:

owdelay

2.1.1. Intended Semantics

Metric Description: To specify spatial and temporal aggregated delay of a stream of packets exchanged between the specified source and destination or the time that the packet spends to travel from source to destination. The spatial aggregation level is specified in the query context (e.g., PID to PID, or endpoint to endpoint).

Metric Representation: The metric value type is a single ‘JSONNumber’ type value containing a non-negative integer component that may be followed by an exponent part. See section 8.4.3 of [I-D.ietf-ippm-initial-registry] for metric unit. The unit is expressed in milliseconds in this document.

2.1.2. Use and Example

This metric could be used as a cost metric constraint attribute used either together with cost metric attribute ‘routingcost’ or on its own or as a returned cost metric in the response.

Example 1: Delay value on source-destination endpoint pairs

POST /endpointcost/lookup HTTP/1.1
Host: alto.example.com
Content-Length: TBA
Content-Type: application/alto-endpointcostparams+json
Accept: application/alto-endpointcost+json, application/alto-error+json

{
    "cost-type": {"cost-mode": "numerical",
                 "cost-metric": "owdelay"},
    "endpoints": {
                   "srcs": [ "ipv4:192.0.2.2" ],
                   "dsts": [ "ipv4:192.0.2.89",
                             "ipv4:198.51.100.34",
                             "ipv6:2000::1:2345:6789:abcd"
                          ]
                   }
}
HTTP/1.1 200 OK
Content-Length: TBA
Content-Type: application/alto-endpointcost+json
{
    "meta": {
        "cost-type": {
            "cost-mode": "numerical",
            "cost-metric": "owdelay"
        }
    },
    "endpoint-cost-map": {
        "ipv4:192.0.2.2": {
            "ipv4:192.0.2.89": 10,
            "ipv4:198.51.100.34": 20,
            "ipv6:2000::1:2345:6789:abcd": 30
        }
    }
}

2.1.3. Measurement Considerations

Method of Measurement or Calculation:

See section 8.3 of [I-D.ietf-ippm-initial-registry] for potential measurement method.

Measurement Point(s) with Potential Measurement Domain:

See Section 4.1, Data sources for potential data sources.

Measurement Timing:

See section 8.3.5 of [I-D.ietf-ippm-initial-registry] for potential measurement timing considerations.

2.2. Cost Metric: Round Trip Time (rtt)

Metric name:

Round Trip Time

Metric Identifier:

rtt
2.2.1. Intended Semantics

Metric Description: To specify spatial and temporal aggregated round trip delay between the specified source and destination or the time that the packet spends to travel from source to destination and then from destination to source. The spatial aggregation level is specified in the query context (e.g., PID to PID, or endpoint to endpoint).

Metric Representation: The metric value type is a single ‘JSONNumber’ type value containing a non-negative integer component that may be followed by an exponent part. See section 4.4.3 of [I-D.ietf-ippm-initial-registry] for Measurement Unit. The unit is expressed in milliseconds in this document.

2.2.2. Use and Example

This metric could be used as a cost metric constraint attribute used either together with cost metric attribute ‘routingcost’ or on its own or as a returned cost metric in the response.

Example 2: Roundtrip Delay value on source-destination endpoint pairs

POST /endpointcost/lookup HTTP/1.1
Host: alto.example.com
Content-Length: TBA
Content-Type: application/alto-endpointcostparams+json
Accept:  application/alto-endpointcost+json,application/alto-error+json

```json
{
  "cost-type": {"cost-mode": "numerical",
    "cost-metric": "rtt"},
  "endpoints": {
    "srcs": [ "ipv4:192.0.2.2" ],
    "dsts": [ "ipv4:192.0.2.89",
      "ipv4:198.51.100.34",
      "ipv6:2000::1:2345:6789:abcd"
    ]
  }
}
```
HTTP/1.1 200 OK
Content-Length: TBA
Content-Type: application/alto-endpointcost+json
{
  "meta": {
    "cost-type": {
      "cost-mode": "numerical",
      "cost-metric": "rtt"
    }
  },
  "endpoint-cost-map": {
    "ipv4:192.0.2.2": {
      "ipv4:192.0.2.89": 4,
      "ipv4:198.51.100.34": 3,
      "ipv6:2000::1:2345:6789:abcd": 2,
    }
  }
}

2.2.3. Measurement Considerations

Method of Measurement or Calculation:

See section 4.3 of [I-D.ietf-ippm-initial-registry] for potential measurement method.

Measurement Point(s) with Potential Measurement Domain:

See section 4.1, Data sources.

Measurement Timing:

See section 4.3.5 of [I-D.ietf-ippm-initial-registry] for Measurement Timing.

2.3. Cost Metric: Packet Delay Variation (pdv)

Metric name:

Packet Delay Variation

Metric Identifier:
2.3.1. Intended Semantics

Metric Description: To specify spatial and temporal aggregated jitter (packet delay variation) with respect to the minimum delay observed on the stream over the specified source and destination. The spatial aggregation level is specified in the query context (e.g., PID to PID, or endpoint to endpoint).

Metric Representation: The metric value type is a single ‘JSONNumber’ type value containing a non-negative integer component that may be followed by an exponent part. See section 5.4.4 of [I-D.ietf-ippm-initial-registry] for Measurement Unit. The unit is expressed in milliseconds in this document.

2.3.2. Use and Example

This metric could be used as a cost metric constraint attribute used either together with cost metric attribute ‘routingcost’ or on its own or as a returned cost metric in the response.
Example 3: PDV value on source-destination endpoint pairs

POST /endpointcost/lookup HTTP/1.1
Host: alto.example.com
Content-Length: TBA
Content-Type: application/alto-endpointcostparams+json
Accept: application/alto-endpointcost+json, application/alto-error+json

```
{
  "cost-type": {"cost-mode": "numerical",
               "cost-metric": "pdv"},
  "endpoints": {
    "srcs": ["ipv4:192.0.2.2"],
    "dsts": ["ipv4:192.0.2.89",
             "ipv4:198.51.100.34",
             "ipv6:2000::1:2345:6789:abcd"
              ]
              }
}
```

HTTP/1.1 200 OK
Content-Length: TBA
Content-Type: application/alto-endpointcost+json

```
{
  "meta": {
    "cost type": {
      "cost-mode": "numerical",
        "cost-metric": "delayjitter"
    }
  },
  "endpoint-cost-map": {
    "ipv4:192.0.2.2": {
      "ipv4:192.0.2.89": 0,
      "ipv4:198.51.100.34": 1,
      "ipv6:2000::1:2345:6789:abcd": 5
    }
  }
}
```

2.3.3. Measurement Considerations

Method of Measurement or Calculation:

See Section 5.3 of [I-D.ietf-ippm-initial-registry] for potential measurement method.
Measurement Point(s) with Potential Measurement Domain:

See Section 4.1, Data sources for potential data sources.

Measurement Timing:

See Section 5.3.5 of [I-D.ietf-ippm-initial-registry] for Measurement Timing.

2.4. Cost Metric: Hop Count

The metric hopcount is mentioned in [RFC7285] Section 9.2.3 as an example. This section further clarifies its properties.

Metric name:

Hop count

Metric Identifier:

hopcount

2.4.1. Intended Semantics

Metric Description:

To specify the number of hops in the path between the source endpoint and the destination endpoint. The hop count is a basic measurement of distance in a network and can be exposed as Router Hops, in direct relation to the routing protocols originating this information.

Metric Representation:

The metric value type is a single ’JSONNumber’ type value containing a non-negative integer component. The unit is integer number.
2.4.2. Use and Example

This metric could be used as a cost metric constraint attribute used either together with cost metric attribute 'routingcost' or on its own or as a returned cost metric in the response.

Example 4: hopcount value on source-destination endpoint pairs

POST /endpointcost/lookup HTTP/1.1
Host: alto.example.com
Content-Length: TBA
Content-Type: application/alto-endpointcostparams+json
Accept: application/alto-endpointcost+json,application/alto-error+json

```
{
  "cost-type": {"cost-mode" : "numerical",
                "cost-metric" : "hopcount"},
  "endpoints" : {
    "srcs": [ "ipv4:192.0.2.2" ],
    "dsts": [ "ipv4:192.0.2.89",
              "ipv4:198.51.100.34",
              "ipv6:2000::1:2345:6789:abcd"
         ]
  }
}
```

HTTP/1.1 200 OK
Content-Length: TBA
Content-Type: application/alto-endpointcost+json

```
{
  "meta": { "cost type": {
              "cost-mode": "numerical",
              "cost-metric": "hopcount"}
           },
  "endpoint-cost-map": {"ipv4:192.0.2.2": {
                        "ipv4:192.0.2.89" : 5,
                        "ipv4:198.51.100.34": 3,
                        "ipv6:2000::1:2345:6789:abcd" : 2,
          }}
}
```
2.4.3. Measurement Considerations

Method of Measurement or Calculation:

The hop count can be calculated based on the number of routers from the source endpoint through which data must pass to reach the destination endpoint.

Measurement Point(s) with Potential Measurement Domain:

The hop count can be measured at the source endpoint by traceroute.

Measurement Timing:

Upon need, the traceroute can use UDP probe message or other implementations that use ICMP and TCP to discover the hop counts along the path from source endpoint to destination endpoint.

2.5. Cost Metric: Packet Loss

Metric name:

Packet loss

Metric Identifier:

pktloss

2.5.1. Intended Semantics

Metric Description:

To specify spatial and temporal aggregated packet loss over the specified source and destination. The spatial aggregation level is specified in the query context (e.g., PID to PID, or endpoint to endpoint).

Metric Representation:
The metric value type is a single 'JSONNumber' type value which be be non-negative integer. The unit is percentile.

2.5.2. Use and Example

This metric could be used as a cost metric constraint attribute used either together with cost metric attribute 'routingcost' or on its own or as a returned cost metric in the response.

Example 5: pktloss value on source-destination endpoint pairs

POST /endpointcost/lookup HTTP/1.1
Host: alto.example.com
Content-Length: TBA
Content-Type: application/alto-endpointcostparams+json
Accept: application/alto-endpointcost+json,application/alto-error+json

```json
{
  "cost-type": { "cost-mode" : "numerical", "cost-metric" : "pktloss" },
  "endpoints" : {
    "srcs": [ "ipv4:192.0.2.2" ],
    "dsts": [ "ipv4:192.0.2.89",
              "ipv4:198.51.100.34",
              "ipv6:2000::1:2345:6789:abcd"
            ]
  }
}
```
HTTP/1.1 200 OK
Content-Length: TBA
Content-Type: application/alto-endpointcost+json
{
    "meta": {
        "cost type": {
            "cost-mode": "numerical",
            "cost-metric": "pktloss"
        }
    },
    "endpoint-cost-map": {
        "ipv4:192.0.2.2": {
            "ipv4:192.0.2.89": 0,
            "ipv4:198.51.100.34": 0,
            "ipv6:2000::1:2345:6789:abcd": 0,
        }
    }
}

2.5.3. Measurement Considerations

Method of Measurement or Calculation:

See Section 2.6 of [RFC7680] for Measurement Method.

Measurement Point(s) with Potential Measurement Domain:

See Section 4.1 this document, Data sources.

Measurement Timing:

See Section 2 and Section 3 of [RFC7680] for Measurement Timing.

2.6. Cost Metric: Throughput

Metric name:

Throughput

Metric Identifier:

throughput
2.6.1. Intended Semantics

Metric Description:

To specify spatial and temporal throughput over the specified source and destination. The spatial aggregation level is specified in the query context (e.g., PID to PID, or endpoint to endpoint).

Metric Representation:

The unit is Mbps.

2.6.2. Use and Example

This metric could be used as a cost metric constraint attribute used either together with cost metric attribute ‘routingcost’ or on its own or as a returned cost metric in the response.

Example 5: throughput value on source-destination endpoint pairs

POST /endpointcost/lookup HTTP/1.1
Host: alto.example.com
Content-Length: TBA
Content-Type: application/alto-endpointcostparams+json
Accept: application/alto-endpointcost+json,application/alto-error+json

{
"cost-type": {"cost-mode" : "numerical",
             "cost-metric" : "throughput"},
"endpoints" : {
    "srcs": [ "ipv4:192.0.2.2" ],
    "dsts": [ "ipv4:192.0.2.89",
              "ipv4:192.0.2.89",
              "ipv4:198.51.100.34",
              "ipv6:2000::1:2345:6789:abcd"
             ]
}
}
2.6.3. Measurement Considerations

Method of Measurement or Calculation:

See Section 3.3 of [RFC6349] for Measurement Method.

Measurement Point(s) with Potential Measurement Domain:

See Section 4.1 of this document.

Measurement Timing:

Similar to RTT. See Section 4.3.5 of [I-D.ietf-ippm-initial-registry] for Measurement Timing.

3. Traffic Engineering Performance Cost Metrics

This section introduces ALTO network performance metrics that may be aggregated from network metrics measured on links and specified in other documents. In particular, the bandwidth related metrics specified in this section are only available through link level measurements. For some of these metrics, the ALTO Server may further expose aggregated values while specifying the aggregation laws.
3.1. Cost Metric: Link Maximum Reservable Bandwidth

Metric name:

Maximum Reservable Bandwidth

Metric Identifier:

maxresbw

3.1.1. Intended Semantics

Metric Description:

To specify spatial and temporal maximum reservable bandwidth over the specified source and destination. The value is corresponding to the maximum bandwidth that can be reserved (motivated from RFC 3630 Sec. 2.5.7.). The spatial aggregation unit is specified in the query context (e.g., PID to PID, or endpoint to endpoint).

Metric Representation:

The metric value type is a single 'JSONNumber' type value that is non-negative. The unit of measurement is mbps.

3.1.2. Use and Example

This metric could be used as a cost metric constraint attribute used either together with cost metric attribute ‘routingcost’ or on its own or as a returned cost metric in the response.
Example 6: maxresbw value on source-destination endpoint pairs

POST/ endpointcost/lookup HTTP/1.1
Host: alto.example.com
Content-Length: TBA
Content-Type: application/alto-endpointcostparams+json
Accept:
    application/alto-endpointcost+json,application/alto-error+json

{
    "cost-type" : 
        { "cost-mode": "numerical",
          "cost-metric": "maxresbw"},
    "endpoints": 
        { 
          "srcs": [ "ipv4 : 192.0.2.2" ],
          "dsts": [ 
            "ipv4:192.0.2.89",
            "ipv4:198.51.100.34",
            "ipv6:2000::1:2345:6789:abcd"
          ]
        }
}

HTTP/1.1 200 OK
Content-Length: TBA
Content-Type: application/alto-endpointcost+json

{
    "meta": 
        { 
          "cost-type": 
              { 
                "cost-mode": "numerical",
                "cost-metric": "maxresbw"
              }
        },
    "endpoint-cost-map": 
        { 
          "ipv4:192.0.2.2" : 
              { 
                "ipv4:192.0.2.89" : 0,
                "ipv4:198.51.100.34" : 2000,
                "ipv6:2000::1:2345:6789:abcd": 5000,
              }
        }
}

3.1.3. Measurement Considerations

Method of Measurement or Calculation:

Maximum Reservable Bandwidth is the bandwidth measured between two directly connected IS-IS neighbors or OSPF neighbors. See Section 3.5 of [RFC5305] for Measurement Method.
Measurement Point(s) with Potential Measurement Domain:

See Section 4.1 this document for discussions.

Measurement Timing:

See Section 3.5 of [RFC5305] and Section 5 of [RFC7810] for Measurement Timing.

3.2. Cost Metric: Link Residue Bandwidth

Metric name:

Residue Bandwidth

Metric Identifier:

residuebw

3.2.1. Intended Semantics

Metric Description:

To specify spatial and temporal residual bandwidth over the specified source and destination. The value is calculated by subtracting tunnel reservations from Maximum Bandwidth (motivated from [RFC7810], Section 4.5.). The spatial aggregation unit is specified in the query context (e.g., PID to PID, or endpoint to endpoint).

Metric Representation:

The metric value type is a single 'JSONNumber' type value that is non-negative. The unit of measurement is mbps.

3.2.2. Use and Example

This metric could be used as a cost metric constraint attribute used either together with cost metric attribute ‘routingcost’ or on its own or as a returned cost metric in the response.
Example 7: residuebw value on source-destination endpoint pairs

POST/ endpointcost/lookup HTTP/1.1
Host: alto.example.com
Content-Length: TBA
Content-Type: application/alto-endpointcostparams+json
Accept: application/alto-endpointcost+json,application/alto-error+json

```
{
  "cost-type": { "cost-mode": "numerical",

3.2.3. Measurement Considerations

Method of Measurement or Calculation:

Residue Bandwidth is the Unidirectional Residue bandwidth measured between two directly connected IS-IS neighbors or OSPF neighbors. See Section 4.5 of [RFC7810] for Measurement Method.
4. Operational Considerations

It can be non-trivial for an ALTO server to derive the metrics. Also, the exact infrastructure and algorithms can vary from different networks, and are outside the scope of this document. However, since they present challenges, we discuss these common challenges.

Also, the performance metrics specified in this document are similar, in that they may use similar data sources and have similar issues in their calculation. Hence, we specify common issues unless one metric has its unique challenges.

4.1. Data Source Considerations

An ALTO server needs data sources to compute the cost metrics described in this document. This document does not define the exact data sources. For example, the ALTO server may use log servers or the OAM system as its data source [RFC7971]. In particular, the cost metrics defined in this document can be computed using routing systems as the data sources. Mechanisms defined in [RFC2681], [RFC3393], [RFC7679], [RFC7680], [RFC3630], [RFC3784], [RFC7471], [RFC7810], [RFC7752] and [I-D.ietf-idr-te-pm-bgp] that allow an ALTO Server to retrieve and derive the necessary information to compute the metrics that we describe in this document.

One challenge lies in the data sources originating the ALTO metric values. The very important purpose of ALTO is to guide application traffic with provider network centric information that may be exposed to ALTO Clients in the form of network performance metric values. Not all of these metrics have values produced by standardized measurement methods or routing protocols. Some of them involve provider-centric policy considerations. Some of them may describe wireless or cellular networks. To reliably guide users and applications while preserving provider privacy, ALTO performance metric values may also add abstraction to measurements or provide unitless performance scores.
4.2. Computation Considerations

The metric values exposed by an ALTO server may result from additional processing on measurements from data sources to compute exposed metrics. This may involve data processing tasks such as aggregating the results across multiple systems, removing outliers, and creating additional statistics. There are two challenges on the computation of ALTO performance metrics.

4.2.1. Configuration Parameters Considerations

Performance metrics often depend on configuration parameters. For example, the value of packet loss rate depends on the measurement interval and varies over time. To handle this issue, an ALTO server may collect data on time periods covering the previous and current time or only collect data on present time. The ALTO server may further aggregate these data to provide an abstract and unified view that can be more useful to applications. To make the ALTO client better understand how to use these performance data, the ALTO server may provide the client with the validity period of the exposed metric values.

4.2.2. Availability Considerations

Applications value information relating to bandwidth availability whereas bandwidth related metrics can often be only measured at the link level. This document specifies a set of link-level bandwidth related values that may be exposed as such by an ALTO server. The server may also expose other metrics derived from their aggregation and having different levels of endpoint granularity, e.g., link endpoints or session endpoints. The metric specifications may also expose the utilized aggregation laws.

5. Security Considerations

The properties defined in this document present no security considerations beyond those in Section 15 of the base ALTO specification [RFC7285].

However concerns addressed in Sections "15.1 Authenticity and Integrity of ALTO Information", "15.2 Potential Undesirable Guidance from Authenticated ALTO Information" and "15.3 Confidentiality of ALTO Information" remain of utmost importance. Indeed, TE performance is a highly sensitive ISP information, therefore, sharing TE metric values in numerical mode requires full mutual confidence between the entities managing the ALTO Server and Client. Numerical TE performance information will most likely be distributed by ALTO Servers to Clients under strict and formal mutual trust agreements.
On the other hand, ALTO Clients must be cognizant on the risks attached to such information that they would have acquired outside formal conditions of mutual trust.

6. IANA Considerations

IANA has created and now maintains the "ALTO Cost Metric Registry", listed in Section 14.2, Table 3 of [RFC7285]. This registry is located at <http://www.iana.org/assignments/alto-protocol/alto-protocol.xhtml#cost-metrics>. This document requests to add the following entries to "ALTO Cost Metric Registry".

Unified Properties for the ALTO Protocol
draft-ietf-alto-unified-props-new-08

Abstract

This document extends the Application-Layer Traffic Optimization (ALTO) Protocol [RFC7285] by generalizing the concept of "endpoint properties" to domains of other entities, and by presenting those properties as maps, similar to the network and cost maps in [RFC7285].

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 9, 2020.

1. Introduction

The ALTO protocol [RFC7285] introduces the concept of "properties" attached to "endpoint addresses", and defines the Endpoint Property Service (EPS) to allow ALTO clients to retrieve those properties. While useful, the EPS, as defined in [RFC7285], has at least two limitations.

First, it allows properties to be associated with only a particular domain of entities, namely individual IP addresses. It is reasonable to think that collections of endpoints, as defined by CIDRs [RFC4632] or PIDs, may also have properties. Since the EPS cannot be extended to new entity domains, new services, with new request and response messages, would have to be defined for new entity domains.

Second, the EPS is only defined as a POST-mode service. Clients must request the properties for an explicit set of endpoint addresses. By contrast, [RFC7285] defines a GET-mode cost map resource which returns all available costs, so a client can get a full set of costs once, and then processes costs lookups without querying the ALTO server. [RFC7285] does not define an equivalent service for endpoint properties. At first a map of endpoint properties might seem impractical, because it could require enumerating the property value for every possible endpoint. But in practice, it is highly unlikely that properties will be defined for every endpoint address. It is much more likely that properties may be defined for only a subset of endpoint addresses, and the specification of properties uses an aggregation representation to allow enumeration. This is particularly true if blocks of endpoint addresses with a common prefix (e.g., a CIDR) have the same value for a property. Entities in other domains may very well allow aggregated representation and hence be enumerable as well.

This document specifies a new approach for defining and retrieving ALTO properties to address the two limitations. Specifically, this document addresses the first limitation by introducing a generic concept called ALTO Entity Domains, where an entity is a generalization of an endpoint to also represent, a PID, a network...
element, or a cell in a cellular network, etc. As a consequence, ALTO Entity Domains defined in this document are a super-set of ALTO Address Types defined in [RFC7285]. Their exact relationship is specified in Section 11.2.1.

Entity domains and property names are extensible. New entity domains can be defined without revising the messages defined in this document, in the same way that new cost metrics and new endpoint properties can be defined without revising the messages defined in [RFC7285].

Additional, this document addresses the second limitation by defining two new types of resources, namely Property Map (see Section 6) and Filtered Property Map (see Section 7). The former is a GET-mode resource which returns the property values for all entities in a domain, and is analogous to a network map or a cost map in [RFC7285]. The latter is a POST-mode resource which returns the values for a set of properties and entities requested by the client, and is analogous to a filtered network map or a filtered cost map.

This document subsumes the Endpoint Property Service defined in [RFC7285], although that service may be retained for legacy clients (see Section 8).

2. Overview: Basic Concepts

Before we define the specification of unified properties, there are several basic concepts which we need to introduce.

2.1. Entity

The entity concept generalizes the concept of the endpoint defined in Section 2.1 of [RFC7285]. An entity is an object that can be an endpoint and is identified by its network address, but can also be an object that has a defined mapping to a set of one or more network addresses or is even not related to any network address.

Examples of eligible entities are:

- a PID, defined in [RFC7285], that has a provider defined human readable abstract identifier defined by a ALTO network map, which maps a PID to a set of ipv4 and ipv6 addresses;
- an autonomous system (AS), that has an AS number (ASN) as its identifier and maps to a set of ipv4 and ipv6 addresses;
- a region representing a country, that is identified by its country code defined by ISO 3166 and maps to a set of cellular addresses;
o a TCP/IP network flow, that has a server defined identifier consisting of the defining TCP/IP 5-Tuple, which is an example that all endpoints are entities while not all entities are endpoints;

o a routing element, that is specified in [RFC7921] and includes routing capability information;

o an abstract network element, that has a server defined identifier and represents a network node, link or their aggregation.

2.2. Entity Property

An entity property defines a property of an entity. It is similar to the endpoint property defined by Section 7.1 of [RFC7285], but can be general besides network-aware.

For example,

o an "ipv4" entity may have a property whose value is an Autonomous System (AS) number indicating the AS which this IPv4 address is owned by;

o a "pid" entity may have a property which indicates the central geographical location of endpoints included by it.

2.3. Property Map

An ALTO property map provides a set of properties for a set of entities. These entities may be in different types. For example, an ALTO property map may define the ASN property for both "ipv4" and "ipv6" entities.

2.4. Information Resource

This document uses the same definition of the information resource as defined by [RFC7285]. Each information resource usually has a JSON format representation following a specific schema defined by its media type.

For example, an ALTO network map resource is represented by a JSON object of type InfoResourceNetworkMap defined by the media type "application/alto-networkmap+json".
2.5. Entity Domain

An entity domain defines a set of entities in the same type. This type is also called the type of this entity domain.

Using entity domains, an ALTO property map can indicate which entities the ALTO client can query to get their properties.

2.5.1. Resource-Specific Entity Domain

To define an entity domain, one naive solution is to enumerate all entities in this entity domain. But it is inefficient when the size of the entity domain is large.

To avoid enumerating all entities, this document introduces an approach called "Resource-Specific Entity Domain" to define entity domains:

Each information resource may define several types of entity domains. And for each type of entity domain, an information resource can define at most one entity domain. For example, an ALTO network map resource can define an IPv4 domain, an IPv6 domain and a pid domain. In this document, these entity domains are called resource-specific entity domains. An ALTO property map only need to indicate which types of entity domain defined by which information resources can be queried, the ALTO client will know which entities are effective to be queried.

2.5.2. Relationship between Entity and Entity Domain

In this document, an entity is owned by exactly one entity domain. It requires that when an ALTO client or server references an entity, it must indicate its entity domain explicitly. Even two entities in two different entity domains may reflect to the same physical or logical object, we treat them as different entities.

Because of this rule, although the resource-specific entity domain approach has no ambiguity, it may introduce redundancy.

2.5.3. Aggregated Entity Domain

Two entities in two different resource-specific entity domains may reflect to the same physical or logical object. For example, the IPv4 entity "192.0.2.34" in the IPv4 domain of the network map "netmap1" and the IPv4 entity "192.0.2.34" in the IPv4 domain of the network map "netmap2" should indicate the same Internet endpoint addressed by the IPv4 address "192.0.2.34".
Each entity in each resource-specific entity domain may only have part of properties of its associated physical or logical object. For example, the IPv4 entity in the IPv4 domain of the network map "netmap1" only has the PID property defined by "netmap1"; same to the IPv4 entity in the IPv4 domain of the network map "netmap2". If the ALTO client wants to get the complete properties, using the resource-specific entity domain, the ALTO client has to query the IPv4 entity "192.0.2.34" twice.

To simplify the query process of the ALTO client, this document introduces the concept "Aggregated Entity Domain". An aggregated entity domain defines an aggregated set of entities coming from multiple resource-specific entity domains in the same type. An entity in the aggregated entity domain includes all properties defined for the associated entity in each associated resource-specific entity domains. For example, the IPv4 entity "192.0.2.34" in the aggregated entity domain between the IPv4 domain of "netmap1" and the IPv4 domain of "netmap2" has PID properties defined by both "netmap1" and "netmap2".

2.5.4. Resource-Specific Entity Property

According to the example of the aggregated entity domain, an entity may have multiple properties in the same type but associated to different information resources. To distinguish them, this document uses the same approach proposed by Section 10.8.1 of [RFC7285], which is called "Resource-Specific Entity Property".

2.6. Scope of Property Map

Using entity domains to organize entities, an ALTO property map resource actually provides a set of properties for some entity domains. If we ignore the syntax sugar of the aggregated entity domain, we can consider an ALTO property map resource just provides a set of (ri, di) => (ro, po) mappings, where (ri, di) means a resource-specific entity domain of type di defined by the information resource ri, and (ro, po) means a resource-specific entity property po defined by the information resource ro.

For each (ri, di) => (ro, po) mapping, the scope of an ALTO property map resource must be one of cases in the following diagram:
<table>
<thead>
<tr>
<th>prop.resource</th>
<th>Export</th>
<th>Non-exist</th>
</tr>
</thead>
<tbody>
<tr>
<td>(ro) = r</td>
<td></td>
<td></td>
</tr>
<tr>
<td>prop.resource</td>
<td>Extend</td>
<td>Define</td>
</tr>
<tr>
<td>(ro) = this</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

where "this" points to the resulting property map resource, "r" presents an existing ALTO information resource other the resulting property map resource.

- **ri = ro = r** ("export" mode): the property map resource just transforms the property mapping \( di \rightarrow po \) defined by \( r \) into the unified representation format and exports it. For example: \( r = \text{"netmap1"}, di = \text{"ipv4"}, po = \text{"pid"} \). The property map resource exports the "ipv4 \( \rightarrow \) pid" mapping defined by "netmap1".

- **ri = r, ro = this** ("extend" mode): the property map extends properties of entities in the entity domain \((r, di)\) and defines a new property \( po \) on them. For example: the property map resource ("this") defines a "geolocation" property on domain "netmap1.pid".

- **ri = ro = this** ("define" mode): the property map defines a new intrinsic entity domain and defines property \( po \) for each entities in this domain. For example: the property map resource ("this") defines a new entity domain "asn" and defines a property "ipprefixes" on this domain.

- **ri = this, ro = r**: in the scope of a property map resource, it does not make sense that another existing ALTO information resource defines a property for this property map resource.

### 2.7. Entity Hierarchy and Property Inheritance

Enumerating all individual effective entities are inefficient. Some types of entities have the hierarchy format, e.g., cidr, which stand for sets of individual entities. Many entities in the same hierarchical format entity sets may have the same property values. To reduce the size of the property map representation, this document introduces an approach called "Property Inheritance". Individual entities can inherit the property from its hierarchical format entity set.
3. Protocol Specification: Basic Data Type

3.1. Entity Domain

3.1.1. Entity Domain Type

An entity domain has a type, which is defined by a string that MUST be no more than 64 characters, and MUST NOT contain characters other than US-ASCII alphanumeric characters (U+0030-U+0039, U+0041-U+005A, and U+0061-U+007A), hyphen (“-”, U+002D), and low line (“_”, U+005F). For example, the strings "ipv4", "ipv6", and "pid" are valid entity domain types.

The type EntityDomainType is used in this document to denote a JSON string confirming to the preceding requirement.

An entity domain type defines the semantics of a type of entity domains. Each entity domain type MUST be registered with the IANA. The format of the entity identifiers (see Section 3.1.3) in that type of entity domains, as well as any hierarchical or inheritance rules (see Section 3.1.4) for those entities, MUST be specified at the same time.

3.1.2. Entity Domain Name

Each entity domain is identified by an entity domain name, a string of the following format:

EntityDomainName ::= [ [ ResourceID ] '.' ] EntityDomainType

This document distinguish three types of entity domains: resource-specific entity domains, self-defined entity domain and aggregated entity domains. Their entity domain names are derived as follows.

Each ALTO information resource MAY define a resource-specific entity domain (which could be empty) in a given entity domain type. A resource-specific entity domain is identified by an entity domain name derived as follows. It MUST start with a resource ID using the ResourceID type defined in [RFC7285], followed by the "." separator (U+002E), followed by an EntityDomainType typed string. For example, if an ALTO server provides two network maps "netmap-1" and "netmap-2", they can define two different "pid" domains identified by "netmap-1.pid" and "netmap-2.pid" respectively. To be simplified, in the scope of a specific information resource, the resource-specific entity domain defined by itself can be identified by the "." EntityDomainType without the ResourceID.
When the associated information resource of a resource-specific entity domain is the current information resource itself, this resource-specific entity domain is a self-defined entity domain, and its ResourceID SHOULD be ignored from its entity domain name.

Given a set of ALTO information resources, there MAY be an aggregated entity domain in a given entity domain type amongst them. An aggregated entity domain is simply identified by its entity domain type. For example, given two network maps "net-map-1" and "net-map-2", "ipv4" and "ipv6" identify two aggregated Internet address entity domains (see Section 4.1) between them.

Note that the "." separator is not allowed in EntityDomainType and hence there is no ambiguity on whether an entity domain name refers to a global entity domain or a resource-specific entity domain.

3.1.3. Entity Identifier

Entities in an entity domain are identified by entity identifiers (EntityID) of the following format:

EntityID ::= EntityDomainName ':' DomainTypeSpecificEntityID

Examples from the Internet address entity domains include individual IP addresses such as "net1.ipv4:192.0.2.14" and "net1.ipv6:2001:db8::12", as well as address blocks such as "net1.ipv4:192.0.2.0/26" and "net1.ipv6:2001:db8::1/48".

The format of the second part of an entity identifier depends on the entity domain type, and MUST be specified when registering a new entity domain type. Identifiers MAY be hierarchical, and properties MAY be inherited based on that hierarchy. Again, the rules defining any hierarchy or inheritance MUST be defined when the entity domain type is registered.

The type EntityID is used in this document to denote a JSON string representing an entity identifier in this format.

Note that two entity identifiers with different textual representations may refer to the same entity, for a given entity domain. For example, the strings "net1.ipv6:2001:db8::1" and "net1.ipv6:2001:db8::0:0:0:0:1" refer to the same entity in the "ipv6" entity domain.
3.1.4. Hierarchy and Inheritance

To make the representation efficient, some types of entity domains MAY allow the ALTO client/server to use a hierarchical format entity identifier to represent a block of individual entities. e.g., In an IPv4 domain "net1.ipv4", a cidr "net1.ipv4:192.0.2.0/26" represents 64 individual IPv4 entities. In this case, the corresponding property inheritance rule MUST be defined for the entity domain type. The hierarchy and inheritance rule MUST have no ambiguity.

3.2. Entity Property

Each entity property has a type to indicate the encoding and the semantics of the value of this entity property, and has a name to be identified. One entity MAY have multiple properties in the same type.

3.2.1. Entity Property Type

The type EntityPropertyType is used in this document to indicate a string denoting an entity property type. The string MUST be no more than 32 characters, and it MUST NOT contain characters other than US-ASCII alphanumeric characters (U+0030-U+0039, U+0041-U+005A, and U+0061-U+007A), the hyphen ("-", U+002D), the colon (":", U+003A), or the low line ("_", U+005F).

Each entity property type MUST be registered with the IANA. The intended semantics of the entity property type MUST be specified at the same time.

To distinguish with the endpoint property type, the entity property type has the following features.

- Some entity property types may be applicable to entities in only particular types of entity domains, not all. For example, the "pid" property is not applicable to entities in a "pid" typed entity domain, but is applicable to entities in the "ipv4" or "ipv6" domains.

- The intended semantics of the value of a entity property may also depend on the the entity domain type of this entity. For example, suppose that the "geo-location" property is defined as the coordinates of a point, encoded as (say) "latitude longitude [altitude]." When applied to an entity that represents a specific host computer, identified by an address in the "ipv4" or "ipv6" entity domain, the property defines the host’s location. However, when applied to an entity in a "pid" domain, the property would
indicate the location of the center of all hosts in this "pid" entity.

3.2.2. Entity Property Name

Each entity property is identified by an entity property name, which is a string of the following format:

EntityPropertyName ::= [ ResourceID ] '.' EntityPropertyType

Similar to the endpoint property type defined in Section 10.8 of [RFC7285], each entity property may be defined by either the property map itself (self-defined) or some other specific information resource (resource-specific).

The entity property name of a resource-specific entity property starts with a string of the type ResourceID defined in [RFC7285], followed by the "." separator (U+002E) and a EntityDomainType typed string. For example, the "pid" properties of an "ipv4" entity defined by two different maps "net-map-1" and "net-map-2" are identified by "net-map-1.pid" and "net-map-2.pid" respectively.

When the associated information resource of the entity property is the current information resource itself, the ResourceID in the property name SHOULD be ignored. For example, the ".asn" property of an "ipv4" entity indicates the AS number of the AS which this IPv4 address is owned by.

3.3. Information Resource Export

Each information resource MAY export a set of entity domains and entity property mappings.

3.3.1. Resource-Specific Entity Domain Export

Each type of information resource MAY export several types of entity domains. For example, a network map resource defines a "pid" domain, a "ipv4" domain and a "ipv6" domain (which may be empty).

When a new ALTO information resource type is registered, if this type of information resource can export an existing type of entity domain, the corresponding document MUST define how to export such type of entity domain from such type of information resource.

When a new entity domain type is defined, if an existing type of information resource can export an entity domain in this entity domain type, the corresponding document MUST define how to export such type of entity domain from such type of information resource.
3.3.2. Entity Property Mapping Export

For each entity domain which could be exported by an information resource, this information resource MAY also export some mapping from this entity domain to some entity property. For example, a network map resource can map an "ipv4" entity to its "pid" property.

When a new ALTO information resource type is registered, if this type of information resource can export an entity domain in an existing entity domain type, and map entities in this entity domain to an existing type of entity property, the corresponding document MUST define how to export such type of an entity property.

When a new ALTO entity domain type or a new entity property type is defined, if an existing type of resource can export an entity domain in this entity domain type, and map entities in this entity domain to this type of entity property, the corresponding document MUST define how to export such type of an entity property.

4. Entity Domain Types

This document defines three entity domain types. The definition of each entity domain type below includes the following: (1) entity domain type name, (2) entity domain-specific entity identifiers, and (3) hierarchy and inheritance semantics. Since a global entity domain type defines a single global entity domain, we say entity domain instead of entity domain type.

4.1. Internet Address Domain Types

The document defines two entity domain types (IPv4 and IPv6) for Internet addresses. Both types are global entity domain types and hence define a corresponding global entity domain as well. Since the two domains use the same hierarchy and inheritance semantics, we define the semantics together, instead of repeating for each.

4.1.1. IPv4 Domain

4.1.1.1. Entity Domain Type

ipv4

4.1.1.2. Domain-Specific Entity Identifiers

Individual addresses are strings as specified by the IPv4Addresses rule of Section 3.2.2 of [RFC3986]; blocks of addresses are prefix-match strings as specified in Section 3.1 of [RFC4632]. For the purpose of defining properties, an individual Internet address and
the corresponding full-length prefix are considered aliases for the
same entity. Thus "ipv4:192.0.2.0" and "ipv4:192.0.2.0/32" are
equivalent.

4.1.2. IPv6 Domain

4.1.2.1. Entity Domain Type

ipv6

4.1.2.2. Domain-Specific Entity Identifiers

Individual addresses are strings as specified by Section 4 of
[ RFC5952 ]; blocks of addresses are prefix-match strings as specified
in Section 7 of [ RFC5952 ]. For the purpose of defining properties,
an individual Internet address and the corresponding 128-bit prefix
are considered aliases for the same entity. That is,
"ipv6:2001:db8::1" and "ipv6:2001:db8::1/128" are equivalent, and
have the same set of properties.

4.1.3. Hierarchy and Inheritance of Internet Address Domains

Both Internet address domains allow property values to be inherited.
Specifically, if a property P is not defined for a specific Internet
address I, but P is defined for some block C which prefix-matches I,
then the address I inherits the value of P defined for block C. If
more than one such block defines a value for P, I inherits the value
of P in the block with the longest prefix. It is important to notice
that this longest prefix rule will ensure no multiple inheritance,
and hence no ambiguity.

Address blocks can also inherit properties: if a property P is not
defined for a block C, but is defined for some block C’ which covers
all IP addresses in C, and C’ has a shorter mask than C, then block C
inherits the property from C’. If there are several such blocks C’,
C inherits from the block with the longest prefix.

As an example, suppose that a server defines a property P for the
following entities:

ipv4:192.0.2.0/26: P=v1
ipv4:192.0.2.0/28: P=v2
ipv4:192.0.2.0/30: P=v3
ipv4:192.0.2.0:   P=v4

Figure 1: Defined Property Values.

Then the following entities have the indicated values:
<table>
<thead>
<tr>
<th>Address</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv4:192.0.2.0:</td>
<td>P=v4</td>
</tr>
<tr>
<td>ipv4:192.0.2.1:</td>
<td>P=v3</td>
</tr>
<tr>
<td>ipv4:192.0.2.16:</td>
<td>P=v1</td>
</tr>
<tr>
<td>ipv4:192.0.2.32:</td>
<td>P=v1</td>
</tr>
<tr>
<td>ipv4:192.0.2.64:</td>
<td>(not defined)</td>
</tr>
<tr>
<td>ipv4:192.0.2.0/32:</td>
<td>P=v4</td>
</tr>
<tr>
<td>ipv4:192.0.2.0/31:</td>
<td>P=v3</td>
</tr>
<tr>
<td>ipv4:192.0.2.0/29:</td>
<td>P=v2</td>
</tr>
<tr>
<td>ipv4:192.0.2.0/27:</td>
<td>P=v1</td>
</tr>
<tr>
<td>ipv4:192.0.2.0/25:</td>
<td>(not defined)</td>
</tr>
</tbody>
</table>

Figure 2: Inherited Property Values.

An ALTO server MAY explicitly indicate a property as not having a value for a particular entity. That is, a server MAY say that property P of entity X is "defined to have no value", instead of "undefined". To indicate "no value", a server MAY perform different behaviours:

- If that entity would inherit a value for that property, then the ALTO server MUST return a "null" value for that property. In this case, the ALTO client MUST recognize a "null" value as "no value" and "do not apply the inheritance rules for this property."

- If the entity would not inherit a value, then the ALTO server MAY return "null" or just omit the property. In this case, the ALTO client cannot infer the value for this property of this entity from the Inheritance rules. So the client MUST interpret that this property has no value.

If the ALTO server does not define any properties for an entity, then the server MAY omit that entity from the response.

4.2. PID Domain

The PID domain associates property values with the PIDs in a network map. Accordingly, this entity domain always depends on a network map.

4.2.1. Entity Domain Type

pid

4.2.2. Domain-Specific Entity Identifiers

The entity identifiers are the PID names of the associated network map.
4.2.3. Hierarchy and Inheritance

There is no hierarchy or inheritance for properties associated with PIDs.

4.2.4. Relationship To Internet Addresses Domains

The PID domain and the Internet address domains are completely independent; the properties associated with a PID have no relation to the properties associated with the prefixes or endpoint addresses in that PID. An ALTO server MAY choose to assign some or all properties of a PID to the prefixes in that PID.

For example, suppose "PID1" consists of the prefix "ipv4:192.0.2.0/24", and has the property "P" with value "v1". The Internet address entities "ipv4:192.0.2.0" and "ipv4:192.0.2.0/24", in the IPv4 domain MAY have a value for the property "P", and if they do, it is not necessarily "v1".

4.3. Internet Address Properties vs. PID Properties

Because the Internet address and PID domains are completely separate, the question may arise as to which entity domain is the best for a property. In general, the Internet address domains are RECOMMENDED for properties that are closely related to the Internet address, or are associated with, and inherited through, blocks of addresses.

The PID domain is RECOMMENDED for properties that arise from the definition of the PID, rather than from the Internet address prefixes in that PID.

For example, because Internet addresses are allocated to service providers by blocks of prefixes, an "ISP" property would be best associated with the Internet address domain. On the other hand, a property that explains why a PID was formed, or how it relates a provider's network, would best be associated with the PID domain.

5. Entity Domains and Property Mappings in Information Resources

5.1. Network Map Resource

The ALTO network map resource defined by the media type "application/alto-networkmap+json" exports the following types of entity domains and entity property mappings.
5.1.1. Resource-Specific Entity Domain

An ALTO network map resource defines a "pid" domain, an "ipv4" domain and an "ipv6" domain by follows:

- The defined "pid" domain includes all PIDs in keys of the "network-map" object.
- The defined "ipv4" domain includes all IPv4 addresses appearing in the "ipv4" field of the endpoint address group of each PID.
- The defined "ipv6" domain includes all IPv6 addresses appearing in the "ipv6" field of the endpoint address group of each PID.

5.1.2. Entity Property Mapping

For each of the preceding entity domains, an ALTO network map resource provides the properties mapping as follows:

ipv4 -> pid: An "networkmap" typed resource can map an "ipv4" entity to a "pid" property whose value is a PID defined by this "networkmap" resource and including the IPv4 address of this entity.

ipv6 -> pid: An "networkmap" typed resource can map an "ipv6" entity to a "pid" property whose value is a PID defined by this "networkmap" resource and including the IPv6 address of this entity.

5.2. Endpoint Property Resource

The ALTO endpoint property resource defined by the media type "application/alto-endpointprop+json" exports the following types of entity domains and entity property mappings.

5.2.1. Resource-Specific Entity Domain

An ALTO endpoint property resource defined an "ipv4" domain and an "ipv6" domain by follows:

- The defined "ipv4" domain includes all IPv4 addresses appearing in keys of the "endpoint-properties" object.
- The defined "ipv6" domain includes all IPv6 addresses appearing in keys of the "endpoint-properties" object.
5.2.2.  Entity Property Mapping

For each of the preceding entity domains, an ALTO endpoint property
resource exports the properties mapping from it to each supported
global endpoint property. The property value is the corresponding
global endpoint property value in the "endpoint-properties" object.

5.3.  Property Map Resource

To avoid the nested reference and its potential complexity, this
document does not specify the export rule of resource-specific entity
domain and entity property mapping for the ALTO property map resource
defined by the media type "application/alto-propmap+json" (see
Section 6.1).

6.  Property Map

A property map returns the properties defined for all entities in one
or more domains, e.g., the "location" property of entities in "pid"
domain, and the "ASN" property of entities in "ipv4" and "ipv6"
domains.

Section 9.4 gives an example of a property map request and its
response.

6.1.  Media Type

The media type of a property map is "application/alto-propmap+json".

6.2.  HTTP Method

The property map is requested using the HTTP GET method.

6.3.  Accept Input Parameters

None.

6.4.  Capabilities

The capabilities are defined by an object of type
PropertyMapCapabilities:
object {  
  EntityPropertyMapping mappings;
} PropertyMapCapabilities;

object-map {  
  EntityDomainName -> EntityPropertyName<1..*>;
} EntityPropertyMapping

with fields:

mappings: A JSON object whose keys are names of entity domains and  
values are the supported entity properties of the corresponding  
entity domains.

6.5. Uses

The "uses" field of a property map resource in an IRD entry specifies  
dependent resources of this property map. It is an array of the  
resource ID(s) of the resource(s).

6.6. Response

If the entity domains in this property map depend on other resources,  
the "dependent-vtags" field in the "meta" field of the response MUST  
be an array that includes the version tags of those resources, and  
the order MUST be consistent with the "uses" field of this property  
map resource. The data component of a property map response is named  "property-map", which is a JSON object of type PropertyMapData,  
where:

object {  
  PropertyMapData property-map;
} InfoResourceProperties : ResponseEntityBase;

object-map {  
  EntityID -> EntityProps;
} PropertyMapData;

object {  
  EntityPropertyName -> JSONValue;
} EntityProps;

The ResponseEntityBase type is defined in Section 8.4 of [RFC7285].

Specifically, a PropertyMapData object has one member for each entity  
in the property map. The entity’s properties are encoded in the  
corresponding EntityProps object. EntityProps encodes one name/value  
pair for each property, where the property names are encoded as
strings of type PropertyName. A protocol implementation SHOULD assume that the property value is either a JSONString or a JSON "null" value, and fail to parse if it is not, unless the implementation is using an extension to this document that indicates when and how property values of other data types are signaled.

For each entity in the property map:

- If the entity is in a resource-specific entity domain, the ALTO server SHOULD only return self-defined properties and resource-specific properties which depend on the same resource as the entity does. The ALTO client SHOULD ignore the resource-specific property in this entity if their mapping is not registered in the ALTO Resource Entity Property Transfer Registry of the type of the corresponding resource.

- If the entity is in a shared entity domain, the ALTO server SHOULD return self-defined properties and all resource-specific properties defined for all resource-specific entities which have the same domain-specific entity identifier as this entity does.

For efficiency, the ALTO server SHOULD omit property values that are inherited rather than explicitly defined; if a client needs inherited values, the client SHOULD use the entity domain’s inheritance rules to deduce those values.

7. Filtered Property Map

A filtered property map returns the values of a set of properties for a set of entities selected by the client.

Section 9.5, Section 9.6, Section 9.7 and Section 9.8 give examples of filtered property map requests and responses.

7.1. Media Type

The media type of a property map resource is "application/alto-propmap+json".

7.2. HTTP Method

The filtered property map is requested using the HTTP POST method.

7.3. Accept Input Parameters

The input parameters for a filtered property map request are supplied in the entity body of the POST request. This document specifies the input parameters with a data format indicated by the media type
"application/alto-propmapparams+json", which is a JSON object of type ReqFilteredPropertyMap:

    object {
        EntityID               entities<1..*>;
        EntityPropertyName     properties<1..*>;
    } ReqFilteredPropertyMap;

with fields:

entities: List of entity identifiers for which the specified properties are to be returned. The ALTO server MUST interpret entries appearing multiple times as if they appeared only once. The domain of each entity MUST be included in the list of entity domains in this resource's "capabilities" field (see Section 7.4).

properties: List of properties to be returned for each entity. Each specified property MUST be included in the list of properties in this resource’s "capabilities" field (see Section 7.4). The ALTO server MUST interpret entries appearing multiple times as if they appeared only once.

Note that the "entities" and "properties" fields MUST have at least one entry each.

7.4. Capabilities

The capabilities are defined by an object of type PropertyMapCapabilities, as defined in Section 6.4.

7.5. Uses

Same to the "uses" field of the Property Map resource (see Section 6.5).

7.6. Response

The response MUST indicate an error, using ALTO protocol error handling, as defined in Section 8.5 of [RFC7285], if the request is invalid.

Specifically, a filtered property map request can be invalid as follows:

- An entity identifier in "entities" in the request is invalid if:
  - The domain of this entity is not defined in the "entity-domains" capability of this resource in the IRD;
* The entity identifier is an invalid identifier in the entity domain.

A valid entity identifier is never an error, even if this filtered property map resource does not define any properties for it.

If an entity identifier in "entities" in the request is invalid, the ALTO server MUST return an "E_INVALID_FIELD_VALUE" error defined in Section 8.5.2 of [RFC7285], and the "value" field of the error message SHOULD indicate this entity identifier.

- A property name in "properties" in the request is invalid if this property name is not defined in the "properties" capability of this resource in the IRD.

It is not an error that a filtered property map resource does not define a requested property’s value for a particular entity. In this case, the ALTO server MUST omit that property from the response for that endpoint.

If a property name in "properties" in the request is invalid, the ALTO server MUST return an "E_INVALID_FIELD_VALUE" error defined in Section 8.5.2 of [RFC7285]. The "value" field of the error message SHOULD indicate the property name.

The response to a valid request is the same as for the Property Map (see Section 6.6), except that:

- If the requested entities include entities in the shared entity domain, the "dependent-vtags" field in its "meta" field MUST include version tags of all dependent resources appearing in the "uses" field.

- If the requested entities only include entities in resource-specific entity domains, the "dependent-vtags" field in its "meta" field MUST include version tags of resources which requested resource-specific entity domains and requested resource-specific properties are dependent on.

- The response only includes the entities and properties requested by the client. If an entity in the request is identified by a hierarchical identifier (e.g., an "ipv4" or "ipv6" address block), the response MUST cover properties for all identifiers in this hierarchical identifier.

It is important that the filtered property map response MUST include all inherited property values for the requested entities and all the
entities which are able to inherit property values from them. To achieve this goal, the ALTO server MAY follow three rules:

- If a property for a requested entity is inherited from another entity not included in the request, the response SHOULD include this property for the requested entity. For example, a full property map may skip a property P for an entity A (e.g., ipv4:192.0.2.0/31) if P can be derived using inheritance from another entity B (e.g., ipv4:192.0.2.0/30). A filtered property map request may include only A but not B. In such a case, the property P SHOULD be included in the response for A.

- If there are entities covered by a requested entity but having different values for the requested properties, the response SHOULD include all those entities and the different property values for them. For example, considering a request for property P of entity A (e.g., ipv4:192.0.2.0/31), if P has value v1 for A1=ipv4:192.0.2.0/32 and v2 for A2=ipv4:192.0.2.1/32, then, the response SHOULD include A1 and A2.

- If an entity in the response is already covered by some other entities in the same response, it SHOULD be removed from the response for compactness. For example, in the previous example, the entity A=ipv4:192.0.2.0/31 SHOULD be removed because A1 and A2 cover all the addresses in A.

An ALTO client should be aware that the entities in the response MAY be different from the entities in its request.

8. Impact on Legacy ALTO Servers and ALTO Clients

8.1. Impact on Endpoint Property Service

Since the property map and the filtered property map defined in this document provide the functionality of the Endpoint Property Service (EPS) defined in Section 11.4 of [RFC7285], it is RECOMMENDED that the EPS be deprecated in favor of Property Map and Filtered Property Map. However, ALTO servers MAY provide an EPS for the benefit of legacy clients.

8.2. Impact on Resource-Specific Properties

Section 10.8 of [RFC7285] defines two categories of endpoint properties: "resource-specific" and "global". Resource-specific property names are prefixed with the ID of the resource they depend upon, while global property names have no such prefix. The property map and the filtered property map defined in this document do not distinguish between those two types of properties. Instead, if there
is a dependency, it is indicated by the "uses" capability of a property map, and is shared by all properties and entity domains in that map. Accordingly, it is RECOMMENDED that resource-specific endpoint properties be deprecated, and no new resource-specific endpoint properties be defined.

8.3. Impact on the pid Property

Section 7.1.1 of [RFC7285] defines the resource-specific endpoint property name "pid", whose value is the name of the PID containing that endpoint. For compatibility with legacy clients, an ALTO server which provides the "pid" property via the EPS MUST use that definition, and that syntax.

However, when used with property maps, this document amends the definition of the "pid" property as follows.

First, the name of the property is simply "pid"; the name is not prefixed with the resource ID of a network map. The "uses" capability of the property map indicates the associated network map. This implies that a property map can only return the "pid" property for one network map; if an ALTO server provides several network maps, it MUST provide a Property Map for each of the network maps.

Second, a client MAY request the "pid" property for a block of Internet addresses. An ALTO server determines the value of "pid" for an address block C as the rules defined in Section 7.6.

Note that although an ALTO server MAY provide a GET-mode property map which returns the entire map for the "pid" property, there is no need to do so, because that map is simply the inverse of the network map.

8.4. Impact on Other Properties

In general, there should be little or no impact on other previously defined properties. The only consideration is that properties can now be defined on blocks of identifiers, rather than just individual identifiers, which might change the semantics of a property.

9. Examples

9.1. Network Map

The examples in this section use a very simple default network map:
defaultpid: ipv4:0.0.0.0/0  ipv6::/0
pid1:        ipv4:192.0.2.0/25
pid2:        ipv4:192.0.2.0/28  ipv4:192.0.2.16/28
pid3:        ipv4:192.0.3.0/28
pid4:        ipv4:192.0.3.16/28

Figure 3: Example Default Network Map

And another simple alternative network map:

defaultpid: ipv4:0.0.0.0/0  ipv6::/0
pid1:        ipv4:192.0.2.0/28  ipv4:192.0.2.16/28
pid2:        ipv4:192.0.3.0/28  ipv4:192.0.3.16/28

Figure 4: Example Alternative Network Map

9.2.  Property Definitions

Beyond "pid", the examples in this section use four additional properties for Internet address domains, "ISP", "ASN", "country" and "state", with the following values:

<table>
<thead>
<tr>
<th>ISP</th>
<th>ASN</th>
<th>country</th>
<th>state</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv4:192.0.2.0/23:</td>
<td>BitsRus</td>
<td>-</td>
<td>us</td>
</tr>
<tr>
<td>ipv4:192.0.2.0/28:</td>
<td>-</td>
<td>12345</td>
<td>-</td>
</tr>
<tr>
<td>ipv4:192.0.2.16/28:</td>
<td>-</td>
<td>12345</td>
<td>-</td>
</tr>
<tr>
<td>ipv4:192.0.2.0:</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>ipv4:192.0.3.0/28:</td>
<td>-</td>
<td>12346</td>
<td>-</td>
</tr>
<tr>
<td>ipv4:192.0.3.16/28:</td>
<td>-</td>
<td>12346</td>
<td>-</td>
</tr>
</tbody>
</table>

Figure 5: Example Property Values for Internet Address Domains

And the examples in this section use the property "region" for the PID domain of the default network map with the following values:

region
pid:defaultpid: -
pid:pid1:    us-west
pid:pid2:    us-east
pid:pid3:    us-south
pid:pid4:    us-north

Figure 6: Example Property Values for Default Network Map’s PID Domain

Note that "-" means the value of the property for the entity is "undefined". So the entity would inherit a value for this property by the inheritance rule if possible. For example, the value of the
"ISP" property for "ipv4:192.0.2.0" is "BitsRus" because of "ipv4:192.0.2.0/24". But the "region" property for "pid:defaultpid" has no value because no entity from which it can inherit.

Similar to the PID domain of the default network map, the examples in this section use the property "ASN" for the PID domain of the alternative network map with the following values:

<table>
<thead>
<tr>
<th>ASN</th>
</tr>
</thead>
<tbody>
<tr>
<td>pid:defaultpid:   -</td>
</tr>
<tr>
<td>pid:pid1:         12345</td>
</tr>
<tr>
<td>pid:pid2:         12346</td>
</tr>
</tbody>
</table>

Figure 7: Example Property Values for Alternative Network Map’s PID Domain

9.3. Information Resource Directory (IRD)

The following IRD defines the relevant resources of the ALTO server. It provides two property maps, one for the "ISP" and "ASN" properties, and another for the "country" and "state" properties. The server could have provided a single property map for all four properties, but did not, presumably because the organization that runs the ALTO server believes any given client is not interested in all four properties.

The server provides two filtered property maps. The first returns all four properties, and the second just returns the "pid" property for the default network map.

The filtered property maps for the "ISP", "ASN", "country" and "state" properties do not depend on the default network map (it does not have a "uses" capability), because the definitions of those properties do not depend on the default network map. The Filtered Property Map for the "pid" property does have a "uses" capability for the default network map, because that defines the values of the "pid" property.

Note that for legacy clients, the ALTO server provides an Endpoint Property Service for the "pid" property for the default network map.

Figure 8: Example IRD

9.4. Property Map Example

The following example uses the properties and IRD defined above to retrieve a Property Map for entities with the "ISP" and "ASN" properties.

Note that, to be compact, the response does not include the entity "ipv4:192.0.2.0", because values of all those properties for this entity are inherited from other entities.

Also note that the entities "ipv4:192.0.2.0/28" and "ipv4:192.0.2.16/28" are merged into "ipv4:192.0.2.0/27", because they have the same value of the "ASN" property. The same rule applies to the entities "ipv4:192.0.3.0/28" and "ipv4:192.0.3.0/28". Both of "ipv4:192.0.2.0/27" and "ipv4:192.0.3.0/27" omit the value for the "ISP" property, because it is inherited from "ipv4:192.0.2.0/23".

GET /propmap/full/inet-ia HTTP/1.1
Host: alto.example.com
Accept: application/alto-propmap+json, application/alto-error+json
HTTP/1.1 200 OK
Content-Length: ###
Content-Type: application/alto-propmap+json

{
   "meta": {
      "dependent-vtags": [
         {"resource-id": "default-network-map",
          "tag": "3ee2cb7e8d63d9fab71b9b34cbf764436315542e"},
         {"resource-id": "alt-network-map",

         "ipv4:192.0.3.0/27": {".ASN": "12346"}
      }
   }
}

9.5. Filtered Property Map Example #1

The following example uses the filtered property map resource to request the "ISP", "ASN" and "state" properties for several IPv4 addresses.

Note that the value of "state" for "ipv4:192.0.2.0" is the only explicitly defined property; the other values are all derived by the inheritance rules for Internet address entities.

  }
}

9.6. Filtered Property Map Example #2

The following example uses the filtered property map resource to request the "ASN", "country" and "state" properties for several IPv4 prefixes.

Note that the property values for both entities "ipv4:192.0.2.0/26" and "ipv4:192.0.3.0/26" are not explicitly defined. They are inherited from the entity "ipv4:192.0.2.0/23".

Also note that some entities like "ipv4:192.0.2.0/28" and "ipv4:192.0.2.16/28" in the response are not listed in the request explicitly. The response includes them because they are refinements of the requested entities and have different values for the requested properties.

The entity "ipv4:192.0.4.0/26" is not included in the response, because there are neither entities which it is inherited from, nor entities inherited from it.
The following example uses the filtered property map resource to request the "pid" property for several IPv4 addresses and prefixes.

Note that the entity "ipv4:192.0.3.0/27" is redundant in the response. Although it can inherit a value of "defaultpid" for the
"pid" property from the entity "ipv4:0.0.0.0/0", none of addresses in it is in "defaultpid". Because blocks "ipv4:192.0.3.0/28" and "ipv4:192.0.3.16/28" have already cover all addresses in that block. So an ALTO server who wants a compact response can omit this entity.

POST /propmap/lookup/pid HTTP/1.1
Host: alto.example.com
Accept: application/alto-propmap+json,application/alto-error+json
Content-Length: ###
Content-Type: application/alto-propmapparams+json

{
  "entities": [
    "ipv4:192.0.2.128",
    "ipv4:192.0.3.0/27"
  ],
  "properties": [ "default-network-map.pid" ]
}

HTTP/1.1 200 OK
Content-Length: ###
Content-Type: application/alto-propmap+json

{
  "meta": {
    "dependent-vtags": [
      {"resource-id": "default-network-map",
       "tag": "3ee2cb7e8d63d9fab71b9b34cbf764436315542e"},
      {"resource-id": "alt-network-map",
       "tag": "c0ce023b8678a7b9ec0324673b98e54656d1f6d"}
    ],
    "property-map": {
      "ipv4:192.0.2.128": {"default-network-map.pid": "defaultpid"},
      "ipv4:192.0.2.0/27": {"default-network-map.pid": "defaultpid"},
      "ipv4:192.0.3.0/28": {"default-network-map.pid": "pid3"},
      "ipv4:192.0.3.16/28": {"default-network-map.pid": "pid4"}
    }
  }
}

9.8. Filtered Property Map Example #4

The following example uses the filtered property map resource to request the "region" property for several PIDs defined in "default-network-map". The value of the "region" property for each PID is not defined by "default-network-map", but the reason why the PID is defined by the network operator.

POST /propmap/lookup/region HTTP/1.1
Host: alto.example.com
Accept: application/alto-propmap+json,application/alto-error+json
Content-Length: ###
Content-Type: application/alto-propmapparams+json

{
  "entities": [
    "default-network-map.pid:pid1",
    "default-network-map.pid:pid2"
  ],
  "properties": [ "region" ]
}

HTTP/1.1 200 OK
Content-Length: ###
Content-Type: application/alto-propmap+json

{
  "meta": {

    ],
    "property-map": {
      "default-network-map.pid:pid1": {
        "region": "us-west"
      },
      "default-network-map.pid:pid2": {
        "region": "us-east"
      }
    }
  }
}

10. Security Considerations

Both Property Map and Filtered Property Map defined in this document fit into the architecture of the ALTO base protocol, and hence the Security Considerations (Section 15 of [RFC7285]) of the base protocol fully apply: authenticity and integrity of ALTO information (i.e., authenticity and integrity of Property Maps), potential undesirable guidance from authenticated ALTO information (e.g., potentially imprecise or even wrong value of a property such as geo-location), confidentiality of ALTO information (e.g., exposure of a potentially sensitive entity property such as geo-location), privacy for ALTO users, and availability of ALTO services should all be considered.
A particular fundamental security consideration when an ALTO server provides a Property Map is to define precisely the policies on who can access what properties for which entities. Security mechanisms such as authentication and confidentiality mechanisms then should be applied to enforce the policy. For example, a policy can be that a property \( P \) can be accessed only by its owner (e.g., the customer who is allocated a given IP address). Then, the ALTO server will need to deploy corresponding mechanisms to realize the policy. The policy may allow non-owners to access a coarse-grained value of the property \( P \). In such a case, the ALTO server may provide a different URI to provide the information.

11. IANA Considerations

This document defines additional application/alto-* media types, and extends the ALTO endpoint property registry.

11.1. application/alto-* Media Types

This document registers two additional ALTO media types, listed in Table 1.

+-----------------+-------------------+------------------------+
| Type            | Subtype           | Specification          |
+-----------------+-------------------+------------------------+
| application     | alto-propmap+json | Section 6.1            |
| application     | alto-propmapparams+json | Section 7.3          |
+-----------------+-------------------+------------------------+

Table 1: Additional ALTO Media Types.

Type name: application

Subtype name: This document registers multiple subtypes, as listed in Table 1.

Required parameters: n/a

Optional parameters: n/a

Encoding considerations: Encoding considerations are identical to those specified for the "application/json" media type. See [RFC7159].

Security considerations: Security considerations related to the generation and consumption of ALTO Protocol messages are discussed in Section 15 of [RFC7285].
Interoperability considerations: This document specifies formats of conforming messages and the interpretation thereof.

Published specification: This document is the specification for these media types; see Table 1 for the section documenting each media type.

Applications that use this media type: ALTO servers and ALTO clients either stand alone or are embedded within other applications.

Additional information:

Magic number(s): n/a

File extension(s): This document uses the mime type to refer to protocol messages and thus does not require a file extension.

Macintosh file type code(s): n/a

Person & email address to contact for further information: See Authors’ Addresses section.

Intended usage: COMMON

Restrictions on usage: n/a

Author: See Authors’ Addresses section.

Change controller: Internet Engineering Task Force (mailto:iesg@ietf.org).

11.2. ALTO Entity Domain Type Registry

This document requests IANA to create and maintain the "ALTO Entity Domain Type Registry", listed in Table 2.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Entity Identifier</th>
<th>Hierarchy &amp; Inheritance</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv4</td>
<td>See Section 4.1.1</td>
<td>See Section 4.1.3</td>
</tr>
<tr>
<td>ipv6</td>
<td>See Section 4.1.2</td>
<td>See Section 4.1.3</td>
</tr>
<tr>
<td>pid</td>
<td>See Section 4.2</td>
<td>None</td>
</tr>
</tbody>
</table>

Table 2: ALTO Entity Domains.
This registry serves two purposes. First, it ensures uniqueness of identifiers referring to ALTO entity domains. Second, it states the requirements for allocated entity domains.

11.2.1. Consistency Procedure between ALTO Address Type Registry and ALTO Entity Domain Registry

One potential issue of introducing the "ALTO Entity Domain Registry" is its relationship with the "ALTO Address Types Registry" already defined in Section 14.4 of [RFC7285]. In particular, the entity identifier of an entity domain registered in the "ALTO Entity Domain Registry" MAY match an address type defined in "ALTO Address Type Registry". It is necessary to precisely define and guarantee the consistency between "ALTO Address Type Registry" and "ALTO Entity Domain Registry".

We define that the ALTO Entity Domain Registry is consistent with ALTO Address Type Registry if two conditions are satisfied:

- When an address type is already or able to be registered in the ALTO Address Type Registry [RFC7285], the same identifier MUST be used when a corresponding entity domain is registered in the ALTO Entity Domain Registry.

- If an ALTO entity domain has the same identifier as an ALTO address type, their addresses encoding MUST be compatible.

To achieve this consistency, the following items MUST be checked before registering a new ALTO entity domain in a future document:

- Whether the ALTO Address Type Registry contains an address type that can be used as an entity identifier for the candidate domain identifier. This has been done for the identifiers "ipv4" and "ipv6" in Table 2.

- Whether the candidate entity identifier of the entity domain is able to be an endpoint address, as defined in Sections 2.1 and 2.2 of [RFC7285].

When a new ALTO entity domain is registered, the consistency with the ALTO Address Type Registry MUST be ensured by the following procedure:

- Test: Do corresponding entity identifiers match a known "network" address type?
  - * If yes (e.g., cell, MAC or socket addresses):
Test: Is such an address type present in the ALTO Address Type Registry?

- If yes: Set the new ALTO entity domain identifier to be the found ALTO address type identifier.
- If no: Define a new ALTO entity domain identifier and use it to register a new address type in the ALTO Address Type Registry following Section 14.4 of [RFC7285].

+ Use the new ALTO entity domain identifier to register a new ALTO entity domain in the ALTO Entity Domain Registry following Section 11.2.2 of this document.

* If no (e.g., pid name, ane name or country code): Proceed with the ALTO Entity Domain registration as described in Section 11.2.2.

11.2.2. ALTO Entity Domain Registration Process

New ALTO entity domains are assigned after IETF Review [RFC5226] to ensure that proper documentation regarding the new ALTO entity domains and their security considerations has been provided. RFCs defining new entity domains SHOULD indicate how an entity in a registered domain is encoded as an EntityId, and, if applicable, the rules defining the entity hierarchy and property inheritance. Updates and deletions of ALTO entity domains follow the same procedure.

Registered ALTO entity domain identifiers MUST conform to the syntactical requirements specified in Section 3.1.2. Identifiers are to be recorded and displayed as strings.

Requests to the IANA to add a new value to the registry MUST include the following information:

- Identifier: The name of the desired ALTO entity domain.
- Entity Identifier Encoding: The procedure for encoding the identifier of an entity of the registered type as an EntityId (see Section 3.1.3). If corresponding entity identifiers of an entity domain match a known "network" address type, the Entity Identifier Encoding of this domain identifier MUST include both Address Encoding and Prefix Encoding of the same identifier registered in the ALTO Address Type Registry [RFC7285]. For the purpose of defining properties, an individual entity identifier and the corresponding full-length prefix MUST be considered aliases for the same entity.
Hierarchical: If the entities form a hierarchy, the procedure for determining that hierarchy.

Inheritance: If entities can inherit property values from other entities, the procedure for determining that inheritance.

Mapping to ALTO Address Type: A boolean value to indicate if the entity domain can be mapped to the ALTO address type with the same identifier.

Security Considerations: In some usage scenarios, entity identifiers carried in ALTO Protocol messages may reveal information about an ALTO client or an ALTO service provider. Applications and ALTO service providers using addresses of the registered type should be made aware of how (or if) the addressing scheme relates to private information and network proximity.

This specification requests registration of the identifiers "ipv4", "ipv6" and "pid", as shown in Table 2.

### 11.3. ALTO Entity Property Type Registry

This document requests IANA to create and maintain the "ALTO Entity Property Type Registry", listed in Table 3.

To distinguish with the "ALTO Endpoint Property Type Registry", each entry in this registry is an ALTO entity property type defined in Section 3.2.1. Thus, registered ALTO entity property type identifier MUST conform to the syntactical requirements specified in that section.

The initial registered ALTO entity property types are listed in Table 3.

+-----------------+---------------------------------+
| Identifier      | Intended Semantics              |
+-----------------+---------------------------------+
| pid             | See Section 7.1.1 of [RFC7285]  |
+-----------------+---------------------------------+

**Table 3: ALTO Entity Property Types.**

Requests to the IANA to add a new value to the registry MUST include the following information:

- **Identifier**: The unique id for the desired ALTO entity property type. The format MUST be as defined in Section 3.2.1 of this
document. It includes the information of the applied ALTO entity domain and the property name.

- Intended Semantics: ALTO entity properties carry with them semantics to guide their usage by ALTO clients. Hence, a document defining a new type SHOULD provide guidance to both ALTO service providers and applications utilizing ALTO clients as to how values of the registered ALTO entity property should be interpreted.

This document requests registration of the identifier "pid", as shown in Table 3.

11.4. ALTO Resource-Specific Entity Domain Registries

11.4.1. Network Map

Media-type: application/alto-networkmap+json

<table>
<thead>
<tr>
<th>Entity Domain Type</th>
<th>Intended Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv4</td>
<td>See Section 5.1.1</td>
</tr>
<tr>
<td>ipv6</td>
<td>See Section 5.1.1</td>
</tr>
<tr>
<td>pid</td>
<td>See Section 5.1.1</td>
</tr>
</tbody>
</table>

Table 4: ALTO Network Map Resource-Specific Entity Domain.

11.4.2. Endpoint Property

Media-type: application/alto-endpointprop+json

<table>
<thead>
<tr>
<th>Entity Domain Type</th>
<th>Intended Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv4</td>
<td>See Section 5.2.1</td>
</tr>
<tr>
<td>ipv6</td>
<td>See Section 5.2.1</td>
</tr>
</tbody>
</table>

Table 5: ALTO Endpoint Property Resource-Specific Entity Domain.

11.5. ALTO Resource Entity Property Mapping Registries

11.5.1. Network Map

Media-type: application/alto-networkmap+json
<table>
<thead>
<tr>
<th>Mapping Descriptor</th>
<th>Entity Domain Type</th>
<th>Property Type</th>
<th>Intended Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv4 -&gt; pid</td>
<td>ipv4</td>
<td>pid</td>
<td>See Section 5.1.2</td>
</tr>
<tr>
<td>ipv6 -&gt; pid</td>
<td>ipv6</td>
<td>pid</td>
<td>See Section 5.1.2</td>
</tr>
</tbody>
</table>

Table 6: ALTO Network Map Entity Property Mapping.

12. Acknowledgments

The authors would like to thank discussions with Kai Gao, Qiao Xiang, Shawn Lin, Xin Wang, Danny Perez, and Vijay Gurbani. The authors thank Dawn Chen (Tongji University), and Shenshen Chen (Tongji/Yale University) for their contributions to earlier drafts.

Multi-domain E2E Network Services  
draft-lachosrothenberg-alto-md-e2e-ns-00

Abstract

Evolving networking scenarios (e.g., 5G) are considering the provision of value-added and on-demand end-to-end (E2E) network services in multi-domain (multi-operator/multi-technology) environments. This document presents different initiatives, mainly within standardization efforts and research projects, working on E2E network services across multiple domains. Problem statement and a layered network model are also described. In addition, this document raises an initial proposal towards a new ALTO service in support of E2E network service requirements. Finally, another important objective of this document is to begin a discussion about motivating use cases in scope of the ALTO WG after the re-chartering process.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on September 12, 2019.

1. Introduction

The fifth generation (5G) of cellular networks is not only considered an evolution but a revolution in the field of information and communication technologies [WHITE-PAPER-5G]. 5G will support the creation of new and novel End-to-End (E2E) services, applications and complex use case scenarios, such as massive Internet of Things, extreme real-time communications, broadband access everywhere, higher user mobility. All these scenarios and services are triggering a modification in the way telecommunication sector deploy new network services, shifting from a commonly manual and long process to a flexible and programmable process.

In this context, cloud computing, Software Defined Networking (SDN), and Network Function Virtualization (NFV) arise as technological
pillars to achieve the necessary function programmability, network programmability, and resource virtualization during the provision of E2E network services.

The delivery of an E2E network service, or simply E2E service, often requires VNFs and their specific order [RFC7665]. Network operators start offering to their customers the possibility of configuring network services with specific requirements in terms of resources (e.g., cpu, memory, hard-disk) and performance objectives (e.g., bandwidth, latency) [VNF-PLAC]. Such demands are usually composed by distributed resources which are expected to available across multiple domains with different technology and/or administration.

This document offers an overview of standardization activities and research projects, including problem statement, behind building E2E services traversing different domains (technological and/or administrative). Moreover, from a layered network model, it is proposed a potential ALTO extension related to E2E Network Service requirements representation based on the ETSI NFV MANO data model.

The overall rationale of this document is to arouse discussions into the ALTO WG concerning potential new items to be considered for the re-charter.

2. Context and Motivation

Different standardization efforts (e.g., IETF, MEF, ETSI) and research projects activities (e.g., 5GEx [H2020.5GEX], 5G-Transformer [H2020-5G-TRANSFORMER], T-NOVA [T-NOVA]) have been focused on multi-domain network service chaining. Standardization is essential to provide recommendations to create interoperable architectures with standardized protocols, and solutions (being developed by different projects) are addressing a diverse range of requirements to provide network services provided using multiple domains.

This section briefly describes, on the one hand, main standardization efforts delivering collections of norms and recommendations, while on the other hand it also provides an overview of several projects formed to develop network services across multiple domains.

2.1. Standardization Activities

2.1.1. IETF

SFC that span domains owned by single or multiple administrative entities are being proposed. The Hierarchical Service Function Chaining (hSFC) [RFC8459], for example, defines an architecture to deploy SFC in large networks. This RFC proposes to decompose the
network into smaller domains (domains under the control of a single organization). Another proposed initiative is [DRAFT-HH-MDSFC] that describes SFC crossing different domains owned by various organizations (e.g., ISPs) or by a single organization with administration partitions. The proposed architecture uses a SFC eXchange Platform (SXP) to collect and exchange information (topology, service states, policies, etc.) between different organizations and it works both in centralized (Multiple SFC domains connected by a logical SXP) and distributed (SXP server as a broker) environments.

More recently, the IETF ALTO WG started to discuss the uses of ALTO as an information model for representing network resource and services in multi-domain scenarios:

- [DRAFT-ALTO-BROKER-MDO] proposes an ALTO-based Broker-assisted architecture where a broker plane works as a coordinator between a set of top-level control planes, i.e., Domain Orchestrators (DOs) and Multi-Domain Orchestrators (MdOs). The ALTO services (with the proposed extensions) provides abstract maps with a simplified, yet enough information view about MdOs involved in the federation. This information includes the abstract network topology, resource availability (e.g., CPUs, Memory, and Storage) and capabilities (e.g., supported network functions).

- [DRAFT-ALTO-UNICORN] presents Unicorn, a resource orchestration framework for multi-domain, geo-distributed data analytics. This work resorts in ALTO as the information model to support the accurate, yet privacy-preserving resource discovery across different domains. The key information to be provided by the use of ALTO including different types of resources, e.g., the computing, storage, and networking resources.

- [DRAFT-MD-SFC-ALTO] describes different standardization activities and research projects addressing the challenges posed by Service Function Chaining (SFC) across multiple domains (specifically, multiple administrative domains). In addition, this document presents an initial approach to realize inter-domain service chaining leveraging the ALTO protocol. Finally, another important concern of this document is to initiate a discussion (ALTO, SFC as well as 9other WGs) regarding if, how, and under what conditions ALTO can be useful to improve the multi-domain SFC process.

2.1.2. ETSI

The ETSI NFV ISG is paving the way toward viable architectural options supporting the efficient placement of functions in different administrative domains. More specifically, the document
[ETSI-NFV-IFA028] reports different NFV MANO architectural approaches with use cases related to network services provided using multiple administrative domains. Besides, it gives a non-exhaustive list of key information to be exchanged between administrative domains (monitoring parameters, topology view, resource capabilities, etc.) and recommendations related to security to permit the correct and proper operation of the final service.

2.1.3. MEF

With its work on the Service Operations Specification MEF 55 [MEF-SOE-MEF55], MEF has defined a reference architecture and framework for describing functional management entities (and interfaces between them) needed to support Lifecycle Service Orchestration (LSO). This LSO architecture enables automated management and control of E2E connectivity services across multiple operator networks. The automated service management includes fulfillment, control, performance, assurance, usage, security, analytics, and policy capabilities that make it possible, for example, expanding the footprint of service providers to interact with potentially several operators to manage and control the access portions of E2E services.

2.2. Research projects

Several projects include an architectural model integrating NFV management with SDN control capabilities to address the challenges towards flexible, dynamic, cost-effective, and on-demand service chaining.

[H2020.5GEX] aims to integrate multiple administrations and technologies through the collaboration between operators in the context of emerging 5G networking. [VITAL][T-NOVA] follow a centralized approach where each domain advertises its capabilities to a federation layer which will act as a broker. In order to avoid one network operator per country or regions, [H2020-5G-NORMA] proposes the use of management and control into a single virtual domain. Also, the 5G-Transformer project [H2020-5G-TRANSFORMER] is defining flexible slicing and federation of transport networking and computing resources across multiple domains. The NECOS project [H2020-NECOS], focused on the realization of E2E multi-domain cloud network slicing, proposes an architectural approach with slice information interfaces for resource exposure and resource discovery during slice provisioning. In addition, the architecture includes a slice marketplace interface between domain orchestrators and a marketplace broker.
3. Problem Statement

3.1. Network Function Placement Decisions

An E2E service request specify virtual nodes (a set of required VNFs) as well as virtual links (the order in which they must be executed). Virtual nodes are deployed in virtual machines hosted by different physical servers, and virtual links correspond to physical paths that connect those servers hosting VNFs. Both virtual nodes and virtual links are limited resources and both may also be located on different technological domains in a single administration and even crossing multiple administrations [VNF-MOB][SFC-ORC]. So that the placement decision problem involves to discover "best" candidate resources and "best" feasible paths between such resources.

3.2. Network Inventory

Placement decisions are a fundamental step for the management and orchestration of network services. Management systems (e.g., DOs, MdOs) need to maintain an inventory of the network providing a real-time representation or view of available infrastructure resources, software resources, and their relationships. However, the size of a network inventory can be very large in scenarios, such as distributed cloud and edge computing. As a result, management systems experiment scalability problems processing large amounts of data to decide where to instantiate a service or part of the service. Therefore, building a network inventory, under these circumstances, needs aggregation mechanisms to reduce time for discovery of resources and to simplify and optimize management of them.

3.3. Publishing Information

Once a network inventory is built, a mechanism for publishing information is also necessary so that the network inventory can provide a simplified, yet enough network information view to management systems. In order to retrieve such information to perform placement decisions, a communication protocol between management systems and network inventory is also necessary.

Therefore, on the one hand, network information (e.g., network locations, costs between them, endhost properties) needs to be advertised to the network applications and, on the other hand, network applications (e.g., DOs, MdOs) needs to describe their requirements and obtain information about resources that suit such requirements.
4. Network Function Virtualization Architectures and Infrastructures

With the introduction of NFV, network functions (e.g., switches, routers, firewalls), and also complex network functions (e.g., EPC) are able to be virtualized and implemented as a collection of virtual machines (VMs) deployed over the virtualized infrastructure. In turn, the virtualized infrastructure is instantiated on a substrate network.

In this context, one of the most accepted NFV architectural frameworks is the proposed by the ETSI ISG NFV working group [ETSI-NFV-WHITEPAPER]. Figure 1 [DRAFT-MD-VIRT] shows this NFV reference architecture. On the left, we can see the data plane: NFVIs hardware/software, VNFs, and optional element management systems. On the right, we see the control plane: VIM which is something like Openstack or Kubernetes, virtual network function managers, and the NFV Orchestrator on the top.
4.1. Layered Network Model

Based on the ETSI NFV reference architecture, a layered network model is identified: Network Service layer, VNF layer, and Resource Layer. This model allows a separation of network relationships in different levels of abstraction. For example, network services can be queried at different levels of abstraction or we can map service paths in different layers (from an abstract to a more concrete layer).

In Figure 2, we have a network service with a set of interconnected VNFs. This network service topology is represented by the Network Service layer.

Figure 1: ETSI MANO Reference Architecture
A VNF is typically divided into a set of virtual function components (VFCs) which comprise the VNF Layer. Each VFC is an application running within a single VM or container.

In case of the resource layer, we have virtual layer and physical layer. The virtual layer represents the virtual overlay network and the physical layer represents the substrate network. Virtualized infrastructures (e.g., VMs, virtual routers) are instantiated on a physical infrastructure.
5. ALTO Extension: E2E Network Service Requirements Representation

From the layered network model described in the previous section, we are considering an ALTO extension related to E2E Network Service requirements representation. An initial proposal has been presented in the ALTO-based Broker-assisted MdO draft [DRAFT-ALTO-BROKER-MDO] where network applications (as ALTO clients) can specify a set of
basic E2E service requirements to an ALTO server in order to obtain candidate resources (domains) and candidate paths.

This initial E2E service requirement representation is inspired on the ETSI NFV MANO data model [ETSI-NFV-MAN001]. This model defines network services as a composition of network functions including the specification of deployment and operational requirements. Such specifications are captured in templates called Network Service Descriptor (NSD) and Virtual Network Function Descriptor (VNFD) that contain (relatively) static information used in the process of on-boarding network services and VNFs, respectively.

- High level objects in a NSD include (among others)
  [ETSI-NFV-MAN001][OSM-DM]:
  * Constituent VNFs: List of VNFDs that are part of the network service.
  * VNF Dependencies: This describes dependencies between VNFs. For example, the order in which the VNFs inside a network service should be started.
  * Network service Connection Points: Each network service has one or more external connection points (which act as endpoints) used to link two network services or to link external networks.
  * Virtual Links: List of Virtual Link Descriptors (VLDs) that describe how VNFs (in the NSD) are connected.

- High level objects in a VNFD include (among others)
  [ETSI-NFV-MAN001][OSM-DM]:
  * Constituent VDUs: List of virtual deployment units (VDUs) in a specific VNF. Each VDU (also referred to VFC) describes the VM/Container capabilities (e.g., CPU, RAM, disks).
  * VDU Dependencies: List of VDU dependencies used for determining the order of startup for VDUs.
  * VNF Connection Points: List of external connection points used for connecting a VNF to other VNFs or to external networks.
  * Internal VLDs: List of internal virtual links to connect various VDUs/VFCs.
6. IANA Considerations

This document includes no request to IANA.

7. Security Considerations

TBD.

ALTO for Multi-Domain Applications: A Review of Use Cases and Design Requirements
draft-xiang-alto-multidomain-usecases-00.txt

Abstract

With the development of novel network technology, such as software defined networking and network function virtualization, many novel multi-domain applications, such as flexible interdomain routing, distributed, federated machine learning and multi-domain collaborative dataset transfer, have been deployed. These applications can benefit substantially from the ALTO protocol [RFC7285], through which the information of multiple networks can be provided to applications. This document first introduces several multi-domain applications and how they can benefit from ALTO. It then describes a generic framework for multi-domain applications to use ALTO to improve the performance, followed by a discussion on new requirements and challenges for ALTO to better support these applications.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on September 12, 2019.
1. Introduction

The ALTO protocol [RFC7285] provides network information to applications so that applications can make network informed decisions to improve the performance. Not only traditional applications such peer-to-peer systems, many recent, novel multi-domain applications,
which orchestrate resources across multiple networks, can also benefit substantially from ALTO.

The goal of this document is to explore how ALTO can help improve the performance of novel multi-domain applications, what ALTO extension services are needed, and what are the corresponding requirements and challenges for designing such extensions. To this end, this document first give a case-by-case review of emerging multi-domain applications and how they can benefit from ALTO. It then describes a generic framework for multi-domain applications to use ALTO to improve the performance, followed by a discussion on the need of new ALTO services and the corresponding requirements and challenges for these extensions to better support these applications.

2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

3. Review of Multi-Domain Applications

3.1. Flexible Interdomain Routing

Flexible interdomain routing can be a highly valuable service for network providers. Specifically, an autonomous system (AS) providing such a service (the provider) allows other ASes (clients) to specify routing actions at the provider based on flexible matching conditions (e.g., match on TCP/IP 5-tuple). In this way, a client AS using the flexible interdomain routing service can offload access and traffic control to provider ASes, leading to a simpler client network configuration while giving the provider ASes additional business opportunities.

3.1.1. How flexible interdomain routing can benefit from ALTO?

ALTO provides provider ASes a standardized approach to expose its routing capability to client ASes. Traditional interdomain routing protocols such as BGP are not good options because they only expose the currently used routes, limiting client ASes’ choices to specify flexible routes. In contrast, ALTO and its extensions provide interfaces for provider ASes to expose not only currently used routes, but also available yet unused routes, to client ASes so that they can have the flexibility to specify different routes for different data traffic.
3.1.2. Example

Consider the example in Figure 1. AS A is compromised and being used to send DDoS traffic to AS E. Without flexible interdomain routing, AS E can setup a firewall locally, but normal traffic from B to E will still be congested at C-D-E due to the existence of malicious traffic from A to E. If AS C provides flexible interdomain routing service, AS E can specify such a firewall at AS C to block DDoS traffic from A, and at the same time avoid the congestion of normal traffic from B to E.

![Figure 1: Flexible interdomain routing for DDoS mitigation.](image)

3.2. Resource Orchestration for Collaborative Data Sciences

As the data volume increases exponentially over time, data analytics is transiting from a single-domain network to a multi-domain, geographically distributed network, where different member networks contribute various resources, e.g., computation, storage and networking resources, to collaboratively collect, share and analyze extremely large amounts of data. Such a paradigm calls for a unified resource orchestration framework to manage a large set of distributively-owned, heterogeneous resources, with the objective of efficient resource utilization, following the autonomy and privacy of different domains.

3.2.1. How multi-domain resource orchestration can benefit from ALTO

One key design challenge for multi-domain resource orchestration is its resource information model. Existing design options such as resource graph and ClassAds are inadequate because they cannot simultaneously (1) allow member networks to provide accurate information on different types of resource, (2) avoid the exposure of private information of member networks such as topology, and (3) allow data analytics jobs to accurately describe their requirements of different types of resources. In contrast, the section 7.1 of
Figure 2 discusses the advantages of choosing ALTO as the resource information model for multi-domain resource orchestration, and how ALTO can simultaneously satisfy the aforementioned design requirements.

3.2.2. Example

Consider an example of three member networks in Figure 2, where s1 and s2 are storage endpoints and d1 and d2 are computation endpoints. Assume a data analytics job is composed of two parallel tasks T1 and T2. T1 needs dataset X as input and T2 needs dataset Y as input.

![Diagram showing multi-domain resource orchestration](image)

Figure 2: Multi-domain resource orchestration.

Using the ALTO endpoint property service, an ALTO client in the resource orchestrator can discover that d1 satisfies the computing requirements of T1 and d2 satisfies the computing requirements of T2. Hence there are only two candidate endpoint pairs: (s1, d1) and (s2, d2).

Afterwards, using the ALTO path vector extension, the ALTO client can retrieve the bandwidth sharing information of task T1 and T2, denoted as x1 and x2, respectively, as follows.

A: \( x_1 + x_2 \leq 10 \text{Mbps} \)

B: \( x_1 \leq 3 \text{Mbps} \)

C: \( x_2 \leq 3 \text{Mbps} \)

With such information, the resource orchestrator can make the optimal resource orchestration decision to reserve 3 Mbps bandwidth for task T1, and 3 Mbps bandwidth for task T2.
3.3. Federated Machine Learning

Instead of moving large-scale datasets from multiple devices / networks to a centralized location for training, federated learning, is a distributed machine learning approach which enables training on distributed datasets residing on different autonomous systems (devices or networks). In this way, only updates on the training model need to be communicated between networks, leading to substantial reduction of networking resource consumption (e.g., saving bandwidth).

3.3.1. How federated machine learning can benefit from ALTO

Federated machine learning requires efficient scheduling algorithms to decide how networking resources should be allocated to transmit training model updates between different ASes. Similar as moving large-scale datasets between multiple ASes, moving updates of training model between ASes can also benefit from the availability of networking information, such as the AS-path and bandwidth sharing. ALTO provides a standardized approach for federated machine learning schedulers to retrieve such information from networks so that adaptive scheduling decisions can be made.

3.3.2. Example

Consider the example in Figure 3, where machine learning workers are located in AS A and D, while AS B and C are transit networks for data traffic transmitted between A and D. When AS A has a large, critical training model update to send to D. It first queries the ALTO servers and B and C for the endpoint cost (e.g., bandwidth) to transmit data from A to D. Suppose the ALTO server at AS B returns an endpoint cost of 10Mbps, while the ALTO server at AS C returns an endpoint cost of 100 Mbps. AS A can then use such information to make the optimal model update scheduling algorithm to send the training model update to AS D via AS C, instead of AS B.
4. A Generic Framework

After reviewing several important, novel multi-domain applications that can benefit substantially from ALTO, this document describes a generic framework for such applications to use ALTO to retrieve information from networks to improve their performance. The high-level architecture of this framework is given in Figure 4.
The top layer of this framework is the application layer, in which each application deploy one or more ALTO clients to query for information provided by networks. The middle layer is the service layer. In this layer, each network deploys one more ALTO servers to respond the queries sent by the ALTO clients from applications, and deploys one or more execution agents to respond to the applications’ resource consumption actions. The bottom layer is the signaling layer, in which each network deploys interdomain protocols / systems, such as routing protocol BGP and resource reservation system OSCARS.

4.1. Workflow

The basic workflow of this framework is as follows.

- An application identifies the networks whose resources (e.g., networking, computation and storage) it may want to consume, and invokes its ALTO clients to query the ALTO servers deployed in those networks for detailed resource information using base ALTO.
protocol and its extension services (e.g., path vector, cost calendar and so on);

- Upon receiving a query from an ALTO client, an ALTO server checks its local information, contacts the underlying signaling layer protocol / system of its residing network if local information is outdated, and returns the latest resource information to the querying ALTO client;

- The applications uses the resource information collected from ALTO servers to make resource allocation decisions (e.g., route selection, resource reservation, etc.), and send such decisions to corresponding execute agents in the corresponding networks (e.g., the simple-reservation-interface of OSCARS).

5. Requirements of ALTO in Multi-Domain Applications

Using ALTO to improve the performance of recent novel multi-domain applications poses several new design requirements. This section discusses these requirements and briefly review existing efforts in the ALTO working group aiming to satisfy them.

5.1. Design Requirements

- Exposing information of alternative resources. Current ALTO protocols and its extensions only provide information of currently used resources (e.g., currently used interdomain route). However, exposing information of alternative resources (e.g., available but not used interdomain routes) may provide the users of new multi-domain applications (e.g., flexible interdomain routing) more flexibility on choosing different resources, giving networks that provide such applications additional business opportunities.

- Providing a unified, accurate representation of multiple types of resources. Current ALTO protocols and its extensions mainly focus on providing network information to applications, with the exception of endpoint property service. However, as new multi-domain applications often consume multiple types of resources across multiple networks, encoding such information accurately in a unified approach is crucial for deploying ALTO to improve such applications’ performance.

- Providing interfaces for more flexible query. Current ALTO protocol and its extensions allows applications to query resource information by specifying IP addresses of endpoints and simple filters. However, with the emerging of new networking architecture (e.g., software defined networking and network function virtualization) and the fine-grained resource requirement
of applications (e.g., link-disjoint paths and endpoint precedence), applications need a more flexible interface to specify queries of resource information.

5.2. Existing Efforts in the ALTO Working Group

Several documents have been submitted to the ALTO working group, with the aim to satisfy one or more of the design requirements discussed above. For example, [DRAFT-PV], [DRAFT-RSA], [DRAFT-UNICORN-INFO] and several other documents propose and apply the ALTO path vector extension to provide accurate networking resource information to support multi-domain resource orchestration. [DRAFT-NFCHAIN] proposes to use ALTO to support resource orchestration for multi-domain service function chaining, and proposes a new ALTO extension to retrieve AS path of network functions across different networks. [DRAFT-CONTEXT] proposes to extend cost information specified in RFC7285 by providing several possible cost values for the same cost metric where each value depends on qualitative criteria as opposed to quantitative criteria such as time. [DRAFT-UR] makes a proposal to use mathematical programming constraint as a generic representation of multiple resources. [DRAFT-FCS] proposes a flexible flow query extension service to allow applications to specify query entities based on flexible matching conditions (e.g., TCP/IP 5-tuple) instead of IP addresses only.

6. Summary

This document reviews several emerging multi-domain applications and how they can benefit from ALTO. It then describes a generic framework for multi-domain applications to use ALTO to improve the performance. In addition, several design requirements are discussed. Though different drafts in the working group have been trying to address one or more these design requirements, a systematic investigation of these issues is still missing. The authors of this document plan to perform such an investigation and make a unified design proposal in the next version of this document.
