Concise Reference Integrity Manifest
draft-birkholz-rats-corim-02

Abstract

Remote Attestation Procedures (RATS) enable Relying Parties to put trust in the trustworthiness of a remote Attester and therefore to decide if to engage in secure interactions with it - or not. Evidence about trustworthiness can be rather complex, voluminous or Attester-specific. As it is deemed unrealistic that every Relying Party is capable of the appraisal of Evidence, that burden is taken on by a Verifier. In order to conduct Evidence appraisal procedures, a Verifier requires not only fresh Evidence from an Attester, but also trusted Endorsements and Reference Values from Endorsers, such as manufacturers, distributors, or owners. This document specifies Concise Reference Integrity Manifests (CoRIM) that represent Endorsements and Reference Values in CBOR format. Composite devices or systems are represented by a collection of Concise Module Identifiers (CoMID) and Concise Software Identifiers (CoSWID) bundled in a CoRIM document.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."
This Internet-Draft will expire on 30 July 2022.

Birkholz, et al. Expires 30 July 2022
1. Introduction

The Remote Attestation Procedures (RATS) architecture [I-D.ietf-rats-architecture] describes appraisal procedures for attestation Evidence and Attestation Results. Appraisal procedures for Evidence are conducted by Verifiers and are intended to assess the trustworthiness of a remote peer. Appraisal procedures for Attestation Results are conducted by Relying Parties and are intended to operationalize the assessment about a remote peer and to act appropriately based on the assessment. In order to enable their intent, appraisal procedures consume Appraisal Policies, Reference Values, and Endorsements.

This document specifies a binary encoding for Reference Values using the Concise Binary Object Representation (CBOR). The encoding is based on three parts that are defined using the Concise Data Definition Language (CDDL):

* Concise Reference Integrity Manifests (CoRIM),
* Concise Module Identifiers (CoMID), and
*
* Concise Software Identifier (CoSWID).

CoRIM and CoMID tags are defined in this document, CoSWID tags are defined in [I-D.ietf-sacm-coswid]. CoRIM provide a wrapper structure, in which CoMID tags, CoSWID tags, as well as corresponding metadata can be bundled and signed as a whole. CoMID tags represent hardware components and provide a counterpart to CoSWID tags, which represent software components.

In accordance to [RFC4949], software components that are stored in hardware modules are referred to as firmware. While firmware can be represented as a software component, it is also very hardware-specific and often resides directly on block devices instead of a file system. In this specification, firmware and their Reference Values are represented via CoMID tags. Reference Values for any other software components stored on a file system are represented via CoSWID tags.

In addition to CoRIM - and respective CoMID tags - this specification defines a Concise Manifest Revocation that represents a list of reference to CoRIM that are actively marked as invalid before their expiration time.

1.1. Requirements Notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

2. Concise Reference Integrity Manifests

This section specifies the Concise RIM (CoRIM) format, the Concise MID format (CoMID), and the extension to the CoSWID specification that augments CoSWID tags to express specific relationships to CoMID tags.

While each specification defines its own start rule, only CoMID and CoSWID are stand-alone specifications. The CoRIM specification - as the bundling format - has a dependency on CoMID and CoSWID and is not a stand-alone specification.
While stand-alone CoSWID tags may be signed [I-D.iets-sacm-coswid], CoMID tags are not intended to be stand-alone and are always part of a CoRIM that must be signed. [I-D.iets-sacm-coswid] specifies the use of COSE [RFC7231] for signing. This specification defines how to generate signed CoRIM tags with COSE to enable proof of authenticity and temper-evidence.

This document uses the Concise Data Definition Language (CDDL [RFC8610]) to define the data structure of CoRIM and CoMID tags, as well as the extensions to CoSWID. The CDDL definitions provide define nested containers. Typically, the CDDL types used for nested containers are maps. Every key used in the maps is a named type that is associated with a corresponding uint via a block of rules appended at the end of the CDDL definition.

Every set of uint keys that is used in the context of the "collision domain" of map is intended to be collision-free (each key is intended to be unique in the scope of a map, not a multimap). To accomplish that, for each map there is an IANA registry for the map members of maps.

2.1. Typographical Conventions

Type names in the following CDDL definitions follow the naming convention illustrated in table Table 1.
Table 1: Type Traits & Typographical Convention

<table>
<thead>
<tr>
<th>type trait</th>
<th>example</th>
<th>typo convention</th>
</tr>
</thead>
<tbody>
<tr>
<td>extensible type choice</td>
<td>int / text / ...</td>
<td>$NAME-type-choice</td>

<td>NAME-map</td>
</tr>
<tr>
<td>flags</td>
<td>&amp; ( a: 1, b: 2 )</td>
<td>NAME-flags</td>
</tr>
</tbody>
</table>

2.2. Prefixes and Namespaces

The semantics of the information elements (attributes) defined for CoRIM, CoMID tags, and CoSWID tags are sometimes very similar, but often do not share the same scope or are actually quite different. In order to not overload the already existing semantics of the software-centric IANA registries of CoSWID tags with, for example, hardware-centric semantics of CoMID tags, new type names are introduced. For example: both CoSWID tags and CoMID tags define a tag-id. As CoSWID already specifies tag-id, the tag-id in CoMID tags is prefixed with comid. to disambiguate the context, resulting in comid.tag-id. This prefixing provides a well-defined scope for the use of the types defined in this document and guarantees interoperability (no type name collisions) with the CoSWID CDDL definition. Effectively, the prefixes used in this specification enable simple hierarchical namespaces. The prefixing introduced is also based on the anticipated namespace features for CDDL.
2.3. Extensibility

Both the CoRIM and the CoMID tag specification include extension points using CDDL sockets (see [RFC8610] Section 3.9). The use of CDDL sockets allows for well-formed extensions to be defined in supplementary CDDL definitions that support additional uses of CoRIM and CoMID tags.

There are two types of extensibility supported via the extension points defined in this document. Both types allow for the addition of keys in the scope of a map.

Custom Keys: The CDDL definition allows for the use of negative integers as keys. These keys cannot take on a well-defined global semantic. They can take on custom-defined semantics in a limited or local scope, e.g. vendor-defined scope.

Registered Keys: Additional keys can be registered at IANA via separate specifications.

Both types of extensibility also allow for the definition of new nested maps that again can include additional defined keys.

2.4. Concise RIM Extension Points

The following CDDL sockets (extension points) are defined in the CoRIM specification, which allow the addition of new information structures to their respective CDDL groups.

Table 2: CoMID CDDL Group Extension Points

</tbody>
</table>

2.5. CDDL Generic Types

The CDDL definitions for CoRIM and CoMID tags use the two following generic types.

2.5.1. Non-Empty

The non-empty generic type is used to express that a map with only optional members MUST at least include one of the optional members.

\[
\text{non-empty}<M> = (M) .\text{within} \{ (+ \text{ any } \Rightarrow \text{ any }) \}
\]

2.5.2. One-Or-More

The one-or-more generic type allows to omit an encapsulating array, if only one member would be present.

\[
\text{one-or-more}<T> = T / [ 2^* T ] ; 2^*
\]
3. Concise RIM Data Definition

A CoRIM is a bundle of CoMID tags and/or CoSWID tags that can reference each other and that includes additional metadata about that bundle.

The root of the CDDL specification provided for CoRIM is the rule corim:

```
start = corim
```

3.1. The signed-corim Container

A CoRIM is signed using [RFC7231]. The additional CoRIM-specific COSE header member label corim-meta is defined as well as the corresponding type corim-meta-map as its value. This rule and its constraints MUST be followed when generating or validating a signed CoRIM tag.

```
signed-corim = #6.18(COSE-Sign1-corim)
```

```
protected-corim-header-map = {
    corim.alg-id => int
    corim.content-type => "application/corim-unsigned+cbor"
    corim.issuer-key-id => bstr
    corim.meta => bstr .cbor corim-meta-map
    * cose-label => cose-values
}
```

```
unprotected-corim-header-map = {
    * cose-label => cose-values
}
```

```
COSE-Sign1-corim = [
    protected: bstr .cbor protected-corim-header-map
    unprotected: unprotected-corim-header-map
    payload: bstr .cbor tagged-corim-map
    signature: bstr
]
```

3.1.1. The corim-meta-map Container

This map contains the two additionally defined attributes corim-signer-map and validity-map that are used to annotate a CoRIM with metadata.
corim-meta-map = {
    corim.signer => corim-signer-map
    ? corim.signature-validity => validity-map
}

corim.signer: One or more entities that created and/or signed the issued CoRIM.

corim.signature-validity: A time period defining the validity span of the signature over the CoRIM.

3.1.2. The corim-signer-map Container

This map is used to identify the signer of a CoRIM via a name and an optional URI.

corim-signer-map = {
    corim.signer-name => $entity-name-type-choice
    ? corim.signer-uri => uri
    * $$corim-signer-map-extension
}

$entity-name-type-choice /= text

corim.signer-name: The name of the organization that signs this CoRIM

corim.signer-uri: An URI uniquely linked to the organization that signs this CoRIM

$$corim-signer-map-extension: This CDDL socket is used to add new information elements to the corim-signer-map container. See FIXME.

3.1.3. The validity-map Container

The members of this map indicate the life-span or period of validity of a CoRIM that is baked into the protected header at the time of signing.

validity-map = {
    ? corim.not-before => time
    corim.not-after => time
}

corim.not-before: The timestamp indicating the CoRIM’s begin of its validity period.
corim.not-after: The timestamp indicating the CoRIM’s end of its validity period.

3.2. The corim-map Container

This map contains the payload of the COSE envelope that is used to sign the CoRIM. This rule and its constraints MUST be followed when generating or validating an unsigned Concise RIM.

corim-map = {
  corim.id => $corim-id-type-choice
  corim.tags => [ + $concise-tag-type-choice ]
  ? corim.dependent-rims => [ + corim-locator-map ]
  ? corim.profile => [ + profile-type-choice ]
  ? corim.rim-validity => validity-map
  ? corim.entities => [ + corim-entity-map ]
  * $$corim-map-extension
}

$corim-id-type-choice /= tstr
$corim-id-type-choice /= uuid-type

profile-type-choice = uri / tagged-oid-type

$concise-tag-type-choice /= #6.505(bytes .cbor concise-swid-tag)
$concise-tag-type-choice /= #6.506(bytes .cbor concise-mid-tag)

corim.id: Typically a UUID or a text string that MUST uniquely identify a CoRIM in a given scope.

corim.tags: A collection of one or more CoMID tags and/or CoSWID tags.

corim.dependent-rims: One or more services available via the Internet that can supply additional, possibly dependent manifests (or other associated resources).

corim.profile: One or more profiles that define the domain of interpretation of the CoMID and/or CoSWID tags.

corim.rim-validity: The validity of the CoRIM expressed as a validity-map.

corim.entities: One or more entities involved in the creation of this CoRIM.

$$corim-map-extension: This CDDL socket is used to add new information elements to the corim-map container. See FIXME.
3.2.1. The corim-entity-map Container

This Container contains qualifying attributes that provide more context information about the RIM as well its origin and purpose. This rule and its constraints MUST be followed when generating or validating a CoRIM tag.

corim-entity-map = {
  corim.entity-name => $entity-name-type-choice
  ? corim.reg-id => uri
  corim.role => $corim-role-type-choice
  * $$corim-entity-map-extension
}

$$corim-role-type-choice /= corim.manifest-creator

corim.entity-name: The name of an organization that performs the roles as indicated by comid.role.

corim.reg-id: The registration identifier of the organization that has authority over the namespace for comid.entity-name.

corim.role: The list of roles the entity is associated with. The entity that generates the CoRIM SHOULD include a $comid-role-type-choice value of corim.manifest-creator.

$$corim-entity-map-extension: This CDDL socket is used to add new information elements to the corim-entity-map container. See FIXME.

3.2.2. The corim-locator-map Container

This map is used to locate and verify the integrity of resources provided by external services, e.g. the CoRIM provider.

corim-locator-map = {
  corim.href => uri
  ? corim.thumbprint => hash-entry
}

corim.href: A pointer to a service that supplies dependent files or records.

corim.thumbprint: A digest of the reference resource.
3.3. The concise-mid-tag Container

The CDDL specification for the root concise-mid-tag map is as follows. This rule and its constraints MUST be followed when generating or validating a CoMID tag.

```
concise-mid-tag = {
  ? comid.language => language-type
  comid.tag-identity => tag-identity-map
  ? comid.entities => [ + entity-map ]
  ? comid.linked-tags => [ + linked-tag-map ]
  comid.triples => triples-map
  * $$concise-mid-tag-extension
}
```

The following describes each member of the concise-mid-tag root map.

- **comid.language**: A textual language tag that conforms with the IANA Language Subtag Registry [IANA.language-subtag-registry].

- **comid.tag-identity**: A composite identifier containing identifying attributes that enable global unique identification of a CoMID tag across versions.

- **comid.entity**: A list of entities that contributed to the CoMID tag.

- **comid.linked-tags**: A list of tags that are linked to this CoMID tag.

- **comid.triples**: A set of relationships in the form of triples, representing a graph-like and semantic reference structure between tags.

- **$$concise-mid-tag-extension**: This CDDL socket is used to add new information elements to the concise-mid-tag root container. See FIXME.

3.4. The tag-identity-map Container

The CDDL specification for the tag-identity-map includes all identifying attributes that enable a consumer of information to anticipate required capabilities to process the corresponding tag that map is included in. This rule and its constraints MUST be followed when generating or validating a CoMID tag.
tag-identity-map = {
    comid.tag-id => $tag-id-type-choice
    comid.tag-version => tag-version-type
}

$tag-id-type-choice /= tstr
$tag-id-type-choice /= uuid-type

tag-version-type = uint .default 0

The following describes each member of the tag-identity-map container.

comid.tag-id: An identifier for a CoMID that MUST be globally unique.

comid.tag-version: An unsigned integer used as a version identifier.

$tag-identity-map-extension: This CDDL socket is used to add new information elements to the tag-identity-map container. See FIXME.

3.5. The entity-map Container

This Container provides qualifying attributes that provide more context information describing the module as well its origin and purpose. This rule and its constraints MUST be followed when generating or validating a CoMID tag.

entity-map = {
    comid.entity-name => $entity-name-type-choice
    ? comid.reg-id => uri
    comid.role => one-or-more<$comid-role-type-choice>
    * $entity-map-extension
}

$comid-role-type-choice /= comid.tag-creator
$comid-role-type-choice /= comid.creator
$comid-role-type-choice /= comid.maintainer

The following describes each member of the tag-identity-map container.

comid.entity-name: The name of an organization that performs the roles as indicated by comid.role.

comid.reg-id: The registration identifier of the organization that has authority over the namespace for comid.entity-name.
comid.role: The list of roles a CoMID entity is associated with. The entity that generates the concise-mid-tag SHOULD include a $comid-role-type-choice value of comid.tag-creator.

$$entity-map-extension: This CDDL socket is used to add new information elements to the entity-map container. See FIXME.

3.6. The linked-tag-map Container

A list of tags that are linked to this CoMID tag.

linked-tag-map = {
    comid.linked-tag-id => $tag-id-type-choice
    comid.tag-rel => $tag-rel-type-choice
}

$tag-rel-type-choice /= comid.supplements
$tag-rel-type-choice /= comid.replaces

The following describes each member of the linked-tag-map container.

comid.linked-tag-id: The tag-id of the linked tag. A linked tag MAY be a CoMID tag or a CoSWID tag.

comid.tag-rel: The relationship type with the linked tag. The relationship type MAY be supplements or replaces, as well as other types well-defined by additional specifications.

3.7. The triples-map Container

A set of directed properties that associate sets of data to provide reference values, endorsed values, verification key material or identifying key material for a specific hardware module that is a component of a composite device. The map provides the core element of CoMID tags that associate remote attestation relevant data with a distinct hardware component that runs an execution environment (a module that is either a Target Environment and/or an Attesting Environment). This rule and its constraints MUST be followed when generating or validating a CoMID tag.

triples-map = non-empty<{
    ? comid.reference-triples => one-or-more<reference-triple-record>
    ? comid.endorsed-triples => one-or-more<endorsed-triple-record>
    ? comid.attest-key-triples => one-or-more<attest-key-triple-record>
    ? comid.identity-triples => one-or-more<identity-triple-record>
    * $$triples-map-extension
}>
The following describes each member of the triple-map container.

comid.reference-triples: A directed property that associates reference measurements with a module that is a Target Environment.

comid.endorsed-triples: A directed property that associates endorsed measurements with a module that is a Target Environment or Attesting Environment.

comid.attest-key-triples: A directed property that associates key material used to verify evidence generated from a module that is an attesting environment.

comid.identity-triples: A directed property that associates key material used to identify a module instance or a module class that is an identifying part of a device(-set).

triples-map-extension: This CDDL socket is used to add new information elements to the triples-map container. See FIXME.

3.8. The environment-map Container

This map represents the module(s) that a triple-map can point directed properties (relationships) from in order to associate them with external information for remote attestation, such as reference values, endorsement and endorsed values, verification key material for evidence, or identifying key material for module (re-)identification. This map can identify a single module instance via comid.instance or groups of modules via comid.group. Referencing classes of modules requires the use of the more complex class-map container. This rule and its constraints MUST be followed when generating or validating a CoMID tag.

environment-map = non-empty<{
  ? comid.class => class-map
  ? comid.instance => $instance-id-type-choice
  ? comid.group => $group-id-type-choice
}> $instance-id-type-choice /= tagged-uuid-type
$group-id-type-choice /= tagged-uuid-type

The following describes each member of the environment-map container.

comid-class: A composite identifier for classes of environments/modules.
comid.instance: An identifier for distinct instances of environments/modules that is either a UEID or a UUID.

comid.group: An identifier for a group of environments/modules that is a UUID.

3.9. The class-map Container

This map enables a composite identifier intended to uniquely identify modules that are of a distinct class of devices. Effectively, all provided members in combination are a composite module class identifier. This rule and its constraints MUST be followed when generating or validating a CoMID tag. This rule and its constraints MUST be followed when generating or validating a CoMID tag.

class-map = non-empty<
  ? comid.class-id => $class-id-type-choice
  ? comid.vendor => tstr
  ? comid.model => tstr
  ? comid.layer => uint
  ? comid.index => uint
>
$\text{class-id-type-choice} /= \text{tagged-oid-type}$
$\text{class-id-type-choice} /= \text{tagged-uuid-type}$
$\text{class-id-type-choice} /= \text{tagged-int-type}$

The following describes each member of the class-map container.

comid.class-id: TODO
comid.vendor TODO
comid.model TODO
comid.layer TODO
comid.index TODO

3.10. The measurement-map and measurement-values-map Containers

One of the targets (range) that a triple-map can point to in order to associate it with a module (domain) is the measurement-map. This map is used to provide reference measurements values that can be compared with Evidence Claim values or Endorsements and endorsed values from other sources than the corresponding CoRIM. measurement-map comes with a measurement key that identifies the measured element with via a OID reference or a UUID. measurement-values-map contains the actual
measurements associated with the module(s). Byte strings with corresponding bit masks that highlights which bits in the byte string are used as reference measurements or endorsement are located in raw-value-group. The members of measurement-values-map provide well-defined and well-scoped semantics for reference measurement or endorsements with respect to a given module instance, class, or group. This rule and its constraints MUST be followed when generating or validating a CoMID tag.

```
measurement-map = {
   ? comid.mkey => $measured-element-type-choice
   comid.mval => measurement-values-map
}

$measured-element-type-choice /= tagged-oid-type
$measured-element-type-choice /= tagged-uuid-type
$measured-element-type-choice /= uint

measurement-values-map = non-empty<{
   ? comid.ver => version-map
   ? comid.svn => svn-type-choice
   ? comid.digests => digests-type
   ? comid.flags => flags-type
   raw-value-group
   ? comid.mac-addr => mac-addr-type-choice
   ? comid.ip-addr => ip-addr-type-choice
   ? comid.serial-number => serial-number-type
   ? comid.ueid => ueid-type
   ? comid.uuid => uuid-type
   ? comid.name => tstr
   * $$measurement-values-map-extension
}>

flags-type = bytes .bits operational-flags

$operational-flags /= &( not-configured: 0 )
$operational-flags /= &( not-secure: 1 )
$operational-flags /= &( recovery: 2 )
$operational-flags /= &( debug: 3 )
$operational-flags /= &( not-replay-protected: 4 )
$operational-flags /= &( not-integrity-protected: 5 )

serial-number-type = text

digests-type = [ + hash-entry ]

The following describes each member of the measurement-map and the measurement-values-map container.
comid.mkey: An identifier for the set of measurements expressed in measurement-values-map that is either an OID or a UUID.

comid.ver: A version number measurement.

comid.svn: A security related version number measurement.

comid.digests: A digest (typically a hash value) measurement.

comid.flags: Measurements that reflect operational modes that are made permanent at manufacturing time such that they are not expected to change during normal operation of the Attester.

raw-value-group: A measurement in the form of a byte string that can come with a corresponding bit mask defining the relevance of each bit in the byte string as a measurement.

comid.mac-addr: An EUI-48 or EUI-64 MAC address measurement.

comid.ip-addr: An IPv4 or IPv6 address measurement.

comid.serial-number: A measurement of a serial number in text.

comid.ueid: A measurement of a Unique Enough Identifier (UEID).

comid.uuid: A measurement of a Universally Unique Identifier (UUID).

comid.name: TODO

$measurement-values-map-extension: This CDDL socket is used to add new information elements to the measurement-values-map container. See FIXME.

3.10.1. The version-map Container

This map expresses reference values about version information.

version-map = {
    comid.version => version-type
? comid.version-scheme => $version-scheme
}

version-type = text .default '0.0.0'

The following describes each member of the version-map container.

comid.version: The version in the form of a text string.
comid-version-scheme: The version-scheme of the text string value as defined in [I-D.ietf-sacm-coswid]

3.10.2. The svn-type-choice Enumeration

This choice defines the CBOR tagged Security Version Numbers (SVN) that can be used as reference values for Evidence and Endorsements.

svn-type = uint
svn = svn-type
min-svn = svn-type
tagged-svn = #6.552(svn)
tagged-min-svn = #6.553(min-svn)
svn-type-choice = tagged-svn / tagged-min-svn

The following describes the types in the svn-type-choice enumeration.

tagged-svn: A specific SVN.
tagged-min-svn: A lower bound for allowed SVN.

3.10.3. The raw-value-group Container

FIXME This group can express a single raw byte value and can come with an optional bit mask that defines which bits in the byte string is used as a reference value, by setting corresponding position in the bit mask to 1.

raw-value-group = (comid.raw-value => $raw-value-type-choice
                  ? comid.raw-value-mask => raw-value-mask-type)

$raw-value-type-choice /= #6.560(bytes)
raw-value-mask-type = bytes

The following describes the types in the raw-value-group Container.

comid.raw-value: FIXME Bit positions in raw-value-type that correspond to bit positions in raw-value-mask-type.
comid.raw-value-mask: A raw-value-mask-type bit corresponding to a bit in raw-value-type MUST be 1 to evaluate the corresponding raw-value-type bit.
3.10.4. The ip-addr-type-choice Enumeration

This type choice expresses IP addresses as reference values.

\[
\text{ip-addr-type-choice} = \text{ip4-addr-type} / \text{ip6-addr-type} \\
\text{ip4-addr-type} = \text{bytes.size 4} \\
\text{ip6-addr-type} = \text{bytes.size 16}
\]

3.10.5. The mac-addr-type-choice Enumeration

This type choice expresses MAC addresses as reference values.

\[
\text{mac-addr-type-choice} = \text{eui48-addr-type} / \text{eui64-addr-type} \\
\text{eui48-addr-type} = \text{bytes.size 6} \\
\text{eui64-addr-type} = \text{bytes.size 8}
\]

3.11. The verification-key-map Container

One of the targets (range) that a triple-map can point to in order to associate it with a module (domain). This map is used to provide the key material for evidence verification (effectively signature checking or a lightweight proof-of-possession of private signing key material) or for identity assertion/check (where a proof-of-possession implies a certain device identity). In support of informed trust decisions, an optional trust anchor in the form a PKIX certification path that is associated with the provided key material can be included. This rule and its constraints MUST be followed when generating or validating a CoMID tag.

\[
\text{verification-key-map} = \{ \\
\text{comid.key} => \text{pkix-base64-key-type} \\
? \text{comid.keychain} => [ + \text{pkix-base64-cert-type} ] \\
\}
\]

pkix-base64-key-type = tstr
pkix-base64-cert-type = tstr

The following describes each member of the verification-key-map container.

comid.key: Verification key material in DER format base64 encoded. Typically, but not necessarily, a public key.

comid.keychain: One or more base64 encoded PKIX certificates. The certificate containing the public key in comid.key MUST be the first certificate. Additional certificates MAY follow. Each subsequent certificate SHOULD certify the previous certificate.
4. Full CDDL Definition

This section aggregates the CDDL definitions specified in this document in a full CDDL definitions including:

* the COSE envelope for CoRIM: signed-corim
* the CoRIM document: unsigned-corim
* the CoMID document: concise-mid-tag

Not included in the full CDDL definition are CDDL dependencies to CoSWID. The following CDDL definitions can be found in [I-D.ietf-sacm-coswid]:

* the COSE envelope for CoRIM: signed-coswid
* the CoSWID document: concise-swid-tag

5. Privacy Considerations

Privacy Considerations

6. Security Considerations

Security Considerations

7. IANA Considerations

This document has a number of IANA considerations, as described in the following subsections. In summary, 6 new registries are established with this request, with initial entries provided for each registry. New values for 5 other registries are also requested.

7.1. COSE Header Parameters Registry

The 'corim metadata' parameter has been added to the "COSE Header Parameters" registry:

* Name: 'corim metadata'
* Label: 11
* Value: corim-meta-map
* Description: Provides a map of additional metadata for a CoRIM payload composed of (1) one or more entities that created or signed the corresponding CoRIM and (2) its period of validity
7.2. CoRIM Map Items Registry

This document defines a new registry titled "CoRIM Map". The registry uses integer values as index values for items in 'unsigned-corim-map' CBOR maps.

Future registrations for this registry are to be made based on [RFC8126] as follows:

<table>
<thead>
<tr>
<th>Range</th>
<th>Registration Procedures</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-127</td>
<td>Standards Action</td>
</tr>
<tr>
<td>128-255</td>
<td>Specification Required</td>
</tr>
</tbody>
</table>

Table 3: CoRIM Map Items Registration Procedures

All negative values are reserved for Private Use.

Initial registrations for the "CoRIM Map" registry are provided below. Assignments consist of an integer index value, the item name, and a reference to the defining specification.

<table>
<thead>
<tr>
<th>Index</th>
<th>Item Name</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>corim.id</td>
<td>RFC-AAAA</td>
</tr>
<tr>
<td>1</td>
<td>corim.tags</td>
<td>RFC-AAAA</td>
</tr>
<tr>
<td>2</td>
<td>corim.dependent-rims</td>
<td>RFC-AAAA</td>
</tr>
<tr>
<td>3-255</td>
<td>Unassigned</td>
<td></td>
</tr>
</tbody>
</table>

Table 4: CoRIM Map Items Initial Registrations

7.3. CoRIM Entity-Map Items Registry

This document defines a new registry titled "CoRIM Entity Map". The registry uses integer values as index values for items in 'corim-entity-map' CBOR maps.
Future registrations for this registry are to be made based on [RFC8126] as follows:

<table>
<thead>
<tr>
<th>Range</th>
<th>Registration Procedures</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-127</td>
<td>Standards Action</td>
</tr>
<tr>
<td>128-255</td>
<td>Specification Required</td>
</tr>
</tbody>
</table>

Table 5: CoRIM Entity Map Items
Registration Procedures

All negative values are reserved for Private Use.

Initial registrations for the "CoRIM Entity Map" registry are provided below. Assignments consist of an integer index value, the item name, and a reference to the defining specification.

<table>
<thead>
<tr>
<th>Index</th>
<th>Item Name</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>corim.entity-name</td>
<td>RFC-AAAA</td>
</tr>
<tr>
<td>1</td>
<td>corim.reg-id</td>
<td>RFC-AAAA</td>
</tr>
<tr>
<td>2</td>
<td>corim.role</td>
<td>RFC-AAAA</td>
</tr>
<tr>
<td>3-255</td>
<td>Unassigned</td>
<td></td>
</tr>
</tbody>
</table>

Table 6: CoRIM Entity Map Items Initial Registrations

7.4. CoRIM Entity-Types Registry

This document defines a new registry titled "CoRIM Entity Types". The registry maintains well-defined integer values as choices for '$entity-name-type-choice' CBOR uints.

Future registrations for this registry are to be made based on [RFC8126] as follows:
All negative values are reserved for Private Use.

Initial registrations for the "CoRIM Entity Types" registry are provided below. Assignments consist of an integer value, the item name, and a reference to the defining specification.

<table>
<thead>
<tr>
<th>Index</th>
<th>Item Name</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>corim.manifest-creator</td>
<td>RFC-AAAA</td>
</tr>
<tr>
<td>1</td>
<td>corim.manifest-signer</td>
<td>RFC-AAAA</td>
</tr>
<tr>
<td>2-255</td>
<td>Unassigned</td>
<td></td>
</tr>
</tbody>
</table>

Table 8: CoRIM Entity Types Initial Registrations

7.5. CoMID Map Items Registry

This document defines a new registry titled "CoMID Map". The registry uses integer values as index values for items in 'concise-mid-tag' CBOR maps.

Future registrations for this registry are to be made based on [RFC8126] as follows:

<table>
<thead>

</tr>
</tbody>
</table>

7.11. rim+cbor Media Type Registration

IANA is requested to add the following to the IANA "Media Types" registry [IANA.media-types].

Type name: application

Subtype name: rim+cbor

Required parameters: none

Optional parameters: none

Encoding considerations: Must be encoded as using [RFC8949]. See RFC-AAAA for details.
Security considerations: See Section 6 of RFC-AAAA.

Interoperability considerations: Applications MAY ignore any key value pairs that they do not understand. This allows backwards compatible extensions to this specification.

Published specification: RFC-AAAA

Applications that use this media type: The type is used by remote attestation procedures, supply chain integrity management systems, vulnerability assessment systems, and in applications that rely on trustworthy endorsements and reference values describing the intended operational state of a system.

Fragment identifier considerations: Fragment identification for application/rim+cbor is supported by using fragment identifiers as specified by Section 9.5 of [RFC8949].

Additional information:

Magic number(s): first five bytes in hex: 43 4f 52 49 4d

File extension(s): corim

Macintosh file type code(s): none

Macintosh Universal Type Identifier code: org.ietf.corim conforms to public.data

Person & email address to contact for further information: Henk Birkholz <henk.birkholz@sit.fraunhofer.de>

Intended usage: COMMON

Restrictions on usage: None

Author: Henk Birkholz <henk.birkholz@sit.fraunhofer.de>

Change controller: IESG

7.12. CoAP Content-Format Registration

IANA is requested to assign a CoAP Content-Format ID for the CoRIM media type in the "CoAP Content-Formats" sub-registry, from the "IETF Review or IESG Approval" space (256..999), within the "CoRE Parameters" registry [RFC7252] [IANA.core-parameters]:
<table>
<thead>
<tr>
<th>Media type</th>

<th>ID</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/rim+cbor</td>
<td>-</td>
<td>TBD1</td>
<td>RFC-AAAA</td>
</tr>
</tbody>
</table>

Table 21: CoAP Content-Format IDs

7.13. CoRIM CBOR Tag Registration

IANA is requested to allocate tags in the "CBOR Tags" registry [IANA.cbor-tags], preferably with the specific value requested:

<table>
<thead>
<tr>
<th>Tag</th>
<th>Data Item</th>
<th>Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>500</td>
<td>tagged array or tagged map</td>
<td>Concise Reference Integrity Manifest (CoRIM) [RFC-AAAA]</td>
</tr>
<tr>

Attestation Results for Secure Interactions
draft-ietf-rats-ar4si-02

Abstract

This document defines reusable Attestation Result information elements. When these elements are offered to Relying Parties as Evidence, different aspects of Attester trustworthiness can be evaluated. Additionally, where the Relying Party is interfacing with a heterogeneous mix of Attesting Environment and Verifier types, consistent policies can be applied to subsequent information exchange between each Attester and the Relying Party.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 8 September 2022.

Voit, et al. Expires 8 September 2022
1. Introduction

The first paragraph of the May 2021 US Presidential Executive Order on Improving the Nation’s Cybersecurity [US-Executive-Order] ends with the statement "the trust we place in our digital infrastructure should be proportional to how trustworthy and transparent that infrastructure is." Later this order explores aspects of trustworthiness such as an auditable trust relationship, which it defines as an "agreed-upon relationship between two or more system elements that is governed by criteria for secure interaction, behavior, and outcomes."

The Remote ATtestation procedureS (RATS) architecture [I-D.ietf-rats-architecture] provides a useful context for programmatically establishing and maintaining such auditable trust relationships. Specifically, the architecture defines conceptual messages conveyed between architectural subsystems to support trustworthiness appraisal. The RATS conceptual message used to convey evidence of trustworthiness is the Attestation Results. The Attestation Results includes Verifier generated appraisals of an Attester including such information as the identity of the Attester, the security mechanisms employed on this Attester, and the Attester’s current state of trustworthiness.

Generated Attestation Results are ultimately conveyed to one or more Relying Parties. Reception of an Attestation Result enables a Relying Party to determine what action to take with regards to an Attester. Frequently, this action will be to choose whether to allow the Attester to securely interact with the Relying Party over some connection between the two.

When determining whether to allow secure interactions with an Attester, a Relying Party is challenged with a number of difficult problems which it must be able to handle successfully. These problems include:

* What Attestation Results (AR) might a Relying Party be willing to trust from a specific Verifier?

* What information does a Relying Party need before allowing interactions or choosing policies to apply to a connection?
* What are the operating/environmental realities of the Attesting Environment where a Relying Party should only be able to associate a certain confidence regarding Attestation Results out of the Verifier? (In other words, different types of Trusted Execution Environments (TEE) need not be treated as equivalent.)

* How to make direct comparisons where there is a heterogeneous mix of Attesting Environments and Verifier types.

To address these problems, it is important that specific Attestation Result information elements are framed independently of Attesting Environment specific constraints. If they are not, a Relying Party would be forced to adapt to the syntax and semantics of many vendor specific environments. This is not a reasonable ask as there can be many types of Attesters interacting with or connecting to a Relying Party.

The business need therefore is for common Attestation Result information element definitions. With these definitions, consistent interaction or connectivity decisions can be made by a Relying Party where there is a heterogenous mix of Attesting Environment types and Verifier types.

This document defines information elements for Attestation Results in a way which normalizes the trustworthiness assertions that can be made from a diverse set of Attesters.

1.1. Requirements Notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

1.2. Terminology

The following terms are imported from [I-D.ietf-rats-architecture]: Appraisal Policy for Attestation Results, Attester, Attesting Environment, Claims, Evidence, Relying Party, Target Environment and Verifier.

[I-D.ietf-rats-architecture] also describes topological patterns that illustrate the need for interoperable conceptual messages. The two patterns called "background-check model" and "passport model" are imported from the RATS architecture and used in this document as a reference to the architectural concepts: Background-Check Model and Passport Model.
Newly defined terms for this document:

AR-augmented Evidence: a bundle of Evidence which includes at least the following:

1. Verifier signed Attestation Results. These Attestation Results must include Identity Evidence for the Attester, a Trustworthiness Vector describing a Verifier’s most recent appraisal of an Attester, and some Verifier Proof-of-Freshness (PoF).

2. A Relying Party PoF which is bound to the Attestation Results of (1) by the Attester’s Attesting Environment signature.

3. Sufficient information to determine the elapsed interval between the Verifier PoF and Relying Party PoF.

Identity Evidence: Evidence which unambiguously identifies an identity. Identity Evidence could take different forms, such as a certificate, or a signature which can be appraised to have only been generated by a specific private/public key pair.

Trustworthiness Claim: a specific quanta of trustworthiness which can be assigned by a Verifier based on its appraisal policy.

Trustworthiness Tier: a categorization of the levels of trustworthiness which may be assigned by a Verifier to a specific Trustworthiness Claim. These enumerated categories are: Affirmed, Warning, Contraindicated, and None.

Trustworthiness Vector: a set of zero to many Trustworthiness Claims assigned during a single appraisal procedure by a Verifier using Evidence generated by an Attester. The vector is included within Attestation Results.

2. Attestation Results for Secure Interactions

A Verifier generates the Attestation Results used by a Relying Party. When a Relying Party needs to determine whether to permit communications with an Attester, these Attestation Results must contain a specific set of information elements. This section defines those information elements, and in some cases encodings for information elements.
2.1. Information driving a Relying Party Action

When the action is a communication establishment attempt with an Attester, there is only a limited set of actions which a Relying Party might take. These actions include:

* Allow or deny information exchange with the Attester. When there is a deny, reasons should be returned to the Attester.

* Establish a transport connection between an Attester and a specific context within a Relying Party (e.g., a TEE, or Virtual Routing Function (VRF).)

* Apply policies on this connection (e.g., rate limits).

There are three categories of information which must be conveyed to the Relying Party (which also is integrated with a Verifier) before it determines which of these actions to take.

1. Non-repudiable Identity Evidence – Evidence which undoubtably identifies one or more entities involved with a communication.

2. Trustworthiness Claims – Specifics a Verifier asserts with regards to its trustworthiness findings about an Attester.

3. Claim Freshness – Establishes the time of last update (or refresh) of Trustworthiness Claims.

The following sections detail requirements for these three categories.

2.2. Non-repudiable Identity

Identity Evidence must be conveyed during the establishment of any trust-based relationship. Specific use cases will define the minimum types of identities required by a particular Relying Party as it evaluates Attestation Results, and perhaps additional associated Evidence. At a bare minimum, a Relying Party MUST start with the ability to verify the identity of a Verifier it chooses to trust. Attester identities may then be acquired through signed or encrypted communications with the Verifier identity and/or the pre-provisioning Attester public keys in the Attester.

During the Remote Attestation process, the Verifier’s identity must be established with a Relying Party, often via a Verifier signature across recent Attestation Results. This Verifier identity could only have come from a key pair maintained by a trusted developer or operator of the Verifier.
Additionally, each set of Attestation Results must be provably and non-reputably bound to the identity of the original Attesting Environment which was evaluated by the Verifier. This is accomplished via satisfying two requirements. First the Verifier signed Attestation Results MUST include sufficient Identity Evidence to ensure that this Attesting Environment signature refers to the same Attesting Environment appraised by the Verifier. Second, where the passport model is used as a subsystem, an Attesting Environment signature which spans the Verifier signature MUST also be included. As the Verifier signature already spans the Attester Identity as well as the Attestation Results, this restricts the viability of spoofing attacks.

In a subset of use cases, these two pieces of Identity Evidence may be sufficient for a Relying Party to successfully meet the criteria for its Appraisal Policy for Attestation Results. If the use case is a connection request, a Relying Party may simply then establish a transport session with an Attester after a successful appraisal. However an Appraisal Policy for Attestation Results will often be more nuanced, and the Relying Party may need additional information. Some Identity Evidence related policy questions which the Relying Party may consider include:

* Does the Relying Party only trust this Verifier to make Trustworthiness Claims on behalf a specific type of Attesting Environment? Might a mix of Verifiers be necessary to cover all mandatory Trustworthiness Claims?

* Does the Relying Party only accept connections from a verified-authentic software build from a specific software developer?

* Does the Relying Party only accept connections from specific preconfigured list of Attesters?

For any of these more nuanced appraisals, additional Identity Evidence or other policy related information must be conveyed or pre-provisioned during the formation of a trust context between the Relying Party, the Attester, the Attester’s Attesting Environment, and the Verifier.

2.2.1. Attester and Attesting Environment

Per [I-D.ietf-rats-architecture] Figure 2, an Attester and a corresponding Attesting Environment might not share common code or even hardware boundaries. Consequently, an Attester implementation needs to ensure that any Evidence which originates from outside the Attesting Environment MUST have been collected and delivered securely before any Attesting Environment signing may occur. After the
Verifier performs its appraisal, it will include sufficient information in the Attestation Results to enable a Relying Party to have confidence that the Attester’s trustworthiness is represented via Trustworthiness Claims signed by the appropriate Attesting Environment.

This document recognizes three general categories of Attesters.

1. HSM-based: A Hardware Security Module (HSM) based cryptoprocessor which hashes one or more streams of security measurements from an Attester within the Attesting Environment. Maintenance of this hash enables detection of an Attester which is lying about the set of security measurements taken. An example of a HSM is a TPM2.0 [TPM2.0].

2. Process-based: An individual process which has its runtime memory encrypted by an Attesting Environment in a way that no other processes can read and decrypt that memory (e.g., [SGX] or [I-D.tschofenig-rats-psa-token].)

3. VM-based: An entire Guest VM (or a set of containers within a host) have been encrypted as a walled-garden unit by an Attesting Environment. The result is that the host operating system cannot read and decrypt what is executing within that VM (e.g., [SEV-SNP] or [TDX].)

Each of these categories of Attesters above will be capable of generating Evidence which is protected using private keys / certificates which are not accessible outside of the corresponding Attesting Environment. The owner of these secrets is the owner of the identity which is bound within the Attesting Environment. Effectively this means that for any Attester identity, there will exist a chain of trust ultimately bound to a hardware-based root of trust in the Attesting Environment. It is upon this root of trust that unique, non-repudiable Attester identities may be founded.

There are several types of Attester identities defined in this document. This list is extensible:

* chip-vendor: the vendor of the hardware chip used for the Attesting Environment (e.g., a primary Endorsement Key from a TPM)

* chip-hardware: specific hardware with specific firmware from an ‘chip-vendor’
* target-environment: a unique instance of a software build running in an Attester (e.g., MRENCLAVE [SGX], an Instance ID [I-D.tschofenig-rats-psa-token], an Identity Block [SEV-SNP], or a hash which represents a set of software loaded since boot (e.g., TPM based integrity verification.))

* target-developer: the organizational unit responsible for a particular 'target-environment' (e.g., MRSIGNER [SGX])

* instance: a unique instantiated instance of an Attesting Environment running on 'chip-hardware' (e.g., an LDevID [IEEE802.1AR])

Based on the category of the Attesting Environment, different types of identities might be exposed by an Attester.

```
+========================+===============+===========+===========+
| Attester Identity type | Process-based | VM-based  | HSM-based |
+========================+===============+===========+===========+
| chip-vendor            | Mandatory     | Mandatory | Mandatory |
+------------------------+---------------+-----------+-----------+
| chip-hardware          | Mandatory     | Mandatory | Mandatory |
+------------------------+---------------+-----------+-----------+
| target-environment     | Mandatory     | Mandatory | Optional  |
+------------------------+---------------+-----------+-----------+
| target-developer       | Mandatory     | Optional  | Optional  |
+------------------------+---------------+-----------+-----------+
| instance               | Optional      | Optional  | Optional  |
+------------------------+---------------+-----------+-----------+
```

Table 1

It is expected that drafts subsequent to this specification will provide the definitions and value domains for specific identities, each of which falling within the Attester identity types listed above. In some cases the actual unique identities might encoded as complex structures. An example complex structure might be a 'target-environment' encoded as a Software Bill of Materials (SBOM).

With the identity definitions and value domains, a Relying Party will have sufficient information to ensure that the Attester identities and Trustworthiness Claims asserted are actually capable of being supported by the underlying type of Attesting Environment. Consequently, the Relying Party SHOULD require Identity Evidence which indicates of the type of Attesting Environment when it considers its Appraisal Policy for Attestation Results.
2.2.2. Verifier

For the Verifier identity, it is critical for a Relying Party to review the certificate and chain of trust for that Verifier. Additionally, the Relying Party must have confidence that the Trustworthiness Claims being relied upon from the Verifier considered the chain of trust for the Attesting Environment.

There are two categorizations Verifier identities defined in this document.

* verifier build: a unique instance of a software build running as a Verifier.

* verifier developer: the organizational unit responsible for a particular ‘verifier build’.

Within each category, communicating the identity can be accomplished via a variety of objects and encodings.

2.2.3. Communicating Identity

Any of the above identities used by the Appraisal Policy for Attestation Results needed to be pre-established by the Relying Party before, or provided during, the exchange of Attestation Results. When provided during this exchange, the identity may be communicated either implicitly or explicitly.

An example of explicit communication would be to include the following Identity Evidence directly within the Attestation Results: a unique identifier for an Attesting Environment, the name of a key which can be provably associated with that unique identifier, and the set of Attestation Results which are signed using that key. As these Attestation Results are signed by the Verifier, it is the Verifier which is explicitly asserting the credentials it believes are trustworthy.

An example of implicit communication would be to include Identity Evidence in the form of a signature which has been placed over the Attestation Results asserted by a Verifier. It would be then up to the Relying Party’s Appraisal Policy for Attestation Results to extract this signature and confirm that it only could have been generated by an Attesting Environment having access to a specific private key. This implicit identity communication is only viable if the Attesting Environment’s public key is already known by the Relying Party.
One final step in communicating identity is proving the freshness of the Attestation Results to the degree needed by the Relying Party. A typical way to accomplish this is to include an element of freshness be embedded within a signed portion of the Attestation Results. This element of freshness reduces the identity spoofing risks from a replay attack. For more on this, see Section 2.4.

2.3. Trustworthiness Claims

2.3.1. Design Principles

Trust is not absolute. Trust is a belief in some aspect about an entity (in this case an Attester), and that this aspect is something which can be depended upon (in this case by a Relying Party.) Within the context of Remote Attestation, believability of this aspect is facilitated by a Verifier. This facilitation depends on the Verifier’s ability to parse detailed Evidence from an Attester and then to assert conclusions about this aspect in a way interpretable by a Relying Party.

Specific aspects for which a Verifier will assert trustworthiness are defined in this section. These are known as Trustworthiness Claims. These claims have been designed to enable a common understanding between a broad array of Attesters, Verifiers, and Relying Parties. The following set of design principles have been applied in the Trustworthiness Claim definitions:

1. Expose a small number of Trustworthiness Claims.

   Reason: a plethora of similar Trustworthiness Claims will result in divergent choices made on which to support between different Verifiers. This would place a lot of complexity in the Relying Party as it would be up to the Relying Party (and its policy language) to enable normalization across rich but incompatible Verifier object definitions.

2. Each Trustworthiness Claim enumerates only the specific states that could viably result in a different outcome after the Policy for Attestation Results has been applied.

   Reason: by explicitly disallowing the standardization of enumerated states which cannot easily be connected to a use case, we avoid forcing implementers from making incompatible guesses on what these states might mean.

3. Verifier and RP developers need explicit definitions of each state in order to accomplish the goals of (1) and (2).
Reason: without such guidance, the Verifier will append plenty of raw supporting info. This relieves the Verifier of making the hard decisions. Of course, this raw info will be mostly non-interpretable and therefore non-actionable by the Relying Party.

4. Support standards and non-standard extensibility for (1) and (2).

Reason: standard types of Verifier generated Trustworthiness Claims should be vetted by the full RATS working group, rather than being maintained in a repository which doesn’t follow the RFC process. This will keep a tight lid on extensions which must be considered by the Relying Party’s policy language. Because this process takes time, non-standard extensions will be needed for implementation speed and flexibility.

These design principles are important to keep the number of Verifier generated claims low, and to retain the complexity in the Verifier rather than the Relying Party.

2.3.2. Enumeration Encoding

Per design principle (2), each Trustworthiness Claim will only expose specific encoded values. To simplify the processing of these enumerations by the Relying Party, the enumeration will be encoded as a single signed 8 bit integer. These value assignments for this integer will be in four Trustworthiness Tiers which follow these guidelines:

None: The Verifier makes no assertions regarding this aspect of trustworthiness.

* Value 0: The Evidence received is insufficient to make a conclusion. Note: this should always be always treated equivalently by the Relying Party as no claim being made. I.e., the RP’s Appraisal Policy for Attestation Results SHOULD NOT make any distinction between a Trustworthiness Claim with enumeration ‘0’, and no Trustworthiness Claim being provided.

* Value 1: The Evidence received contains unexpected elements which the Verifier is unable to parse. An example might be that the wrong type of Evidence has been delivered.

* Value -1: A verifier malfunction occurred during the Verifier’s appraisal processing.

Affirming: The Verifier affirms the Attester support for this aspect of trustworthiness.
Values 2 to 31: A standards enumerated reason for affirming.

Values -2 to -32: A non-standard reason for affirming.

Warning: The Verifier warns about this aspect of trustworthiness.

Values 32 to 95: A standards enumerated reason for the warning.

Values -33 to -96: A non-standard reason for the warning.

Contraindicated: The Verifier asserts the Attester is explicitly untrustworthy in regard to this aspect.

Values 96 to 127: A standards enumerated reason for the contraindication.

Values -97 to -128: A non-standard reason for the contraindication.

This enumerated encoding listed above will simplify the Appraisal Policy for Attestation Results. Such a policies may be as simple as saying that a specific Verifier has recently asserted Trustworthiness Claims, all of which are Affirming.

2.3.3. Assigning a Trustworthiness Claim value

In order to simplify design, only a single encoded value is asserted by a Verifier for any Trustworthiness Claim within a using the following process.

1. If applicable, a Verifier MUST assign a standardized value from the Contraindicated tier.

2. Else if applicable, a Verifier MUST assign a non-standardized value from the Contraindicated tier.

3. Else if applicable, a Verifier MUST assign a standardized value from the Warning tier.

4. Else if applicable, a Verifier MUST assign a non-standardized value from the Warning tier.

5. Else if applicable, a Verifier MUST assign a standardized value from the Affirming tier.

6. Else if applicable, a Verifier MUST assign a non-standardized value from the Affirming tier.
7. Else a Verifier MAY assign a 0 or -1.

2.3.4. Specific Claims

Following are the Trustworthiness Claims and their supported enumerations which may be asserted by a Verifier:

configuration: A Verifier has appraised an Attester’s configuration, and is able to make conclusions regarding the exposure of known vulnerabilities

0: No assertion
1: Verifier cannot parse unexpected Evidence.
-1: Verifier malfunction
2: The configuration is a known and approved config.
3: The configuration includes or exposes no known vulnerabilities.
32: The configuration includes or exposes known vulnerabilities.
96: The configuration is unsupportable as it exposes unacceptable security vulnerabilities.
99: Cryptographic validation of the Evidence has failed.

executables: A Verifier has appraised and evaluated relevant runtime files, scripts, and/or other objects which have been loaded into the Target environment’s memory.

0: No assertion
1: Verifier cannot parse unexpected Evidence.
-1: Verifier malfunction
2: Only a recognized genuine set of approved executables, scripts, files, and/or objects have been loaded during and after the boot process.
3: Only a recognized genuine set of approved executables have been loaded during the boot process.
32: Only a recognized genuine set of executables, scripts, files,
and/or objects have been loaded. However the Verifier cannot vouch for a subset of these due to known bugs or other known vulnerabilities.

33: Runtime memory includes executables, scripts, files, and/or objects which are not recognized.

96: Runtime memory includes executables, scripts, files, and/or object which are contraindicated.

99: Cryptographic validation of the Evidence has failed.

file-system: A Verifier has evaluated a specific set of directories within the Attester’s file system. (Note: the Verifier may or may not indicate what these directory and expected files are via an unspecified management interface.)

0: No assertion

1: Verifier cannot parse unexpected Evidence.

-1: Verifier malfunction

2: Only a recognized set of approved files are found.

32: The file system includes unrecognized executables, scripts, or files.

96: The file system includes contraindicated executables, scripts, or files.

99: Cryptographic validation of the Evidence has failed.

hardware: A Verifier has appraised any Attester hardware and firmware which are able to expose fingerprints of their identity and running code.

0: No assertion

1: Verifier cannot parse unexpected Evidence.

-1: Verifier malfunction

2: An Attester has passed its hardware and/or firmware verifications needed to demonstrate that these are genuine/supported.
32: An Attester contains only genuine/supported hardware and/or firmware, but there are known security vulnerabilities.

96: Attester hardware and/or firmware is recognized, but its trustworthiness is contraindicated.

97: A Verifier does not recognize an Attester’s hardware or firmware, but it should be recognized.

99: Cryptographic validation of the Evidence has failed.

instance-identity: A Verifier has appraised an Attesting Environment’s unique identity based upon private key signed Evidence which can be correlated to a unique instantiated instance of the Attester. (Note: this Trustworthiness Claim should only be generated if the Verifier actually expects to recognize the unique identity of the Attester.)

0: No assertion

1: Verifier cannot parse unexpected Evidence.

-1: Verifier malfunction

2: The Attesting Environment is recognized, and the associated instance of the Attester is not known to be compromised.

96: The Attesting Environment is recognized, and but its unique private key indicates a device which is not trustworthy.

97: The Attesting Environment is not recognized; however the Verifier believes it should be.

99: Cryptographic validation of the Evidence has failed.

runtime-opaque: A Verifier has appraised the visibility of Attester objects in memory from perspectives outside the Attester.

0: No assertion

1: Verifier cannot parse unexpected Evidence.

-1: Verifier malfunction

2: the Attester’s executing Target Environment and Attesting
Environments are encrypted and within Trusted Execution Environment(s) opaque to the operating system, virtual machine manager, and peer applications. (Note: This value corresponds to the protections asserted by O.RUNTIME_CONFIDENTIALITY from [GP-TEE-PP])

32: the Attester’s executing Target Environment and Attesting Environments inaccessible from any other parallel application or Guest VM running on the Attester’s physical device. (Note that unlike "1" these environments are not encrypted in a way which restricts the Attester’s root operator visibility. See O.TA_ISOLATION from [GP-TEE-PP].)

96: The Verifier has concluded that in memory objects are unacceptably visible within the physical host that supports the Attester.

99: Cryptographic validation of the Evidence has failed.

sourced-data: A Verifier has evaluated of the integrity of data objects from external systems used by the Attester.

0: No assertion

1: Verifier cannot parse unexpected Evidence.

-1: Verifier malfunction

2: All essential Attester source data objects have been provided by other Attester(s) whose most recent appraisal(s) had both no Trustworthiness Claims of "0" where the current Trustworthiness Claim is "Affirming", as well as no "Warning" or "Contraindicated" Trustworthiness Claims.

32: Attester source data objects come from unattested sources, or attested sources with "Warning" type Trustworthiness Claims.

96: Attester source data objects come from contraindicated sources.

99: Cryptographic validation of the Evidence has failed.

storage-opaque: A Verifier has appraised that an Attester is capable of encrypting persistent storage. (Note: Protections must meet the capabilities of [OMTP-ATE] Section 5, but need not be hardware tamper resistant.)

0: No assertion
1: Verifier cannot parse unexpected Evidence.

-1: Verifier malfunction

2: the Attester encrypts all secrets in persistent storage via using keys which are never visible outside an HSM or the Trusted Execution Environment hardware.

32: the Attester encrypts all persistently stored secrets, but without using hardware backed keys

96: There are persistent secrets which are stored unencrypted in an Attester.

99: Cryptographic validation of the Evidence has failed.

It is possible for additonal Trustworthiness Claims and enumerated values to be defined in subsequent documents. At the same time, the standardized Trustworthiness Claim values listed above have been designed so there is no overlap within a Trustworthiness Tier. As a result, it is possible to imagine a future where overlapping Trustworthiness Claims within a single Trustworthiness Tier may be defined. Wherever possible, the Verifier SHOULD assign the best fitting standardized value.

Where a Relying Party doesn’t know how to handle a particular Trustworthiness Claim, it MAY choose an appropriate action based on the Trustworthiness Tier under which the enumerated value fits.

It is up to the Verifier to publish the types of evaluations it performs when determining how Trustworthiness Claims are derived for a type of any particular type of Attester. It is out of the scope of this document for the Verifier to provide proof or specific logic on how a particular Trustworthiness Claim which it is asserting was derived.

2.3.5. Trustworthiness Vector

Multiple Trustworthiness Claims may be asserted about an Attesting Environment at single point in time. The set of Trustworthiness Claims inserted into an instance of Attestation Results by a Verifier is known as a Trustworthiness Vector. The order of Claims in the vector is NOT meaningful. A Trustworthiness Vector with no Trustworthiness Claims (i.e., a null Trustworthiness Vector) is a valid construct. In this case, the Verifier is making no Trustworthiness Claims but is confirming that an appraisal has been made.
2.3.6. Trustworthiness Vector for a type of Attesting Environment

Some Trustworthiness Claims are implicit based on the underlying type of Attesting Environment. For example, a validated MRSIGNER identity can be present where the underlying [SGX] hardware is 'hw-authentic'. Where such implicit Trustworthiness Claims exist, they do not have to be explicitly included in the Trustworthiness Vector. However, these implicit Trustworthiness Claims SHOULD be considered as being present by the Relying Party. Another way of saying this is if a Trustworthiness Claim is automatically supported as a result of coming from a specific type of TEE, that claim need not be redundantly articulated. Such implicit Trustworthiness Claims can be seen in the tables within Appendix B.2 and Appendix B.3.

Additionally, there are some Trustworthiness Claims which cannot be adequately supported by an Attesting Environment. For example, it would be difficult for an Attester that includes only a TPM (and no other TEE) from ever having a Verifier appraise support for 'runtime-opaque'. As such, a Relying Party would be acting properly if it rejects any non-supportable Trustworthiness Claims asserted from a Verifier.

As a result, the need for the ability to carry a specific Trustworthiness Claim will vary by the type of Attesting Environment. Example mappings can be seen in Appendix B.

2.4. Freshness

A Relying Party will care about the recentness of the Attestation Results, and the specific Trustworthiness Claims which are embedded. All freshness mechanisms of [I-D.ietf-rats-architecture], Section 10 are supportable by this specification.

Additionally, a Relying Party may track when a Verifier expires its confidence for the Trustworthiness Claims or the Trustworthiness Vector as a whole. Mechanisms for such expiry are not defined within this document.

There is a subset of secure interactions where the freshness of Trustworthiness Claims may need to be revisited asynchronously. This subset is when trustworthiness depends on the continuous availability of a transport session between the Attester and Relying Party. With such connectivity dependent Attestation Results, if there is a reboot which resets transport connectivity, all established Trustworthiness Claims should be cleared. Subsequent connection re-establishment will allow fresh new Trustworthiness Claims to be delivered.
3. Secure Interactions Models

There are multiple ways of providing a Trustworthiness Vector to a Relying Party. This section describes two alternatives.

3.1. Background-Check

3.1.1. Verifier Retrieval

It is possible to for a Relying Party to follow the Background-Check Model defined in Section 5.2 of [I-D.ietf-rats-architecture]. In this case, a Relying Party will receive Attestation Results containing the Trustworthiness Vector directly from a Verifier. These Attestation Results can then be used by the Relying Party in determining the appropriate treatment for interactions with the Attester.

While applicable in some cases, the utilization of the Background-Check Model without modification has potential drawbacks in other cases. These include:

* Verifier scale: if the Attester has many Relying Parties, a Verifier appraising that Attester could be frequently be queried based on the same Evidence.

* Information leak: Evidence which the Attester might consider private can be visible to the Relying Party. Hiding that Evidence could devalue any resulting appraisal.

* Latency: a Relying Party will need to wait for the Verifier to return Attestation Results before proceeding with secure interactions with the Attester.

An implementer should examine these potential drawbacks before selecting this alternative.

3.1.2. Co-resident Verifier

A simplified Background-Check Model may exist in a very specific case.
This is where the Relying Party and Verifier functions are co-resident. This model is appropriate when:

* Some hardware-based private key is used by an Attester while proving its identity as part of a mutually authenticated secure channel establishment with the Relying Party, and
Internet-Draft             Attestation Results                March 2022

* this Attester identity is accepted as sufficient proof of Attester integrity.

Effectively this means that detailed forensic capabilities of a robust Verifier are unnecessary because it is accepted that the code and operational behavior of the Attester cannot be manipulated after TEE initialization.

An example of such a scenario may be when an SGX’s MRENCLAVE and MRSIGNER values have been associated with a known QUOTE value. And the code running within the TEE is not modifiable after launch.

3.2. Below Zero Trust

Zero Trust Architectures are referenced in [US-Executive-Order] eleven times. However despite this high profile, there is an architectural gap with Zero Trust. The credentials used for authentication and admission control can be manipulated on the endpoint. Attestation can fill this gap through the generation of a compound credential called AR-augmented Evidence. This compound credential is rooted in the hardware based Attesting Environment of an endpoint, plus the trustworthiness of a Verifier. The overall solution is known as "Below Zero Trust" as the compound credential cannot be manipulated or spoofed by an administrator of an endpoint with root access. This solution is not adversely impacted by the potential drawbacks with pure background-check described above.

To kick-off the "Below Zero Trust" compound credential creation sequence, a Verifier evaluates an Attester and returns signed Attestation Results back to this original Attester no less frequently than a well-known interval. This interval may also be asynchronous, based on the changing of certain Evidence as described in [I-D.ietf-rats-network-device-subscription].

When a Relying Party is to receive information about the Attester’s trustworthiness, the Attesting Environment assembles the minimal set of Evidence which can be used to confirm or refute whether the Attester remains in the state of trustworthiness represented by the AR. To this Evidence, the Attesting Environment appends the signature from the most recent AR as well as a Relying Party Proof-of-Freshness. The Attesting Environment then signs the combination.

The Attester then assembles AR Augmented Evidence by taking the signed combination and appending the full AR. The assembly now consists of two independent but semantically bound sets of signed Evidence.
The AR Augmented Evidence is then sent to the Relying Party. The Relying Party then can appraise these semantically bound sets of signed Evidence by applying an Appraisal Policy for Attestation Results as described below. This policy will consider both the AR as well as additional information about the Attester within the AR Augmented Evidence when determining what action to take.

This alternative combines the [I-D.ietf-rats-architecture] Sections 5.1 Passport Model and Section 5.2 Background-Check Model. Figure 1 describes this flow of information. The flows within this combined model are mapped to [I-D.ietf-rats-architecture] in the following way. "Verifier A" below corresponds to the "Verifier" Figure 5 within [I-D.ietf-rats-architecture]. And "Relying Party/Verifier B" below corresponds to the union of the "Relying Party" and "Verifier" boxes within Figure 6 of [I-D.ietf-rats-architecture]. This union is possible because Verifier B can be implemented as a simple, self-contained process. The resulting combined process can appraise the AR-augmented Evidence to determine whether an Attester qualifies for secure interactions with the Relying Party. The specific steps of this process are defined later in this section.

---

Figure 1: Below Zero Trust
The interaction model depicted above includes specific time related events from Appendix A of [I-D.ietf-rats-architecture]. With the identification of these time related events, time duration/interval tracking becomes possible. Such duration/interval tracking can become important if the Relying Party cares if too much time has elapsed between the Verifier PoF and Relying Party PoF. If too much time has elapsed, perhaps the Attestation Results themselves are no longer trustworthy.

Note that while time intervals will often be relevant, there is a simplified case that does not require a Relying Party’s PoF in step (3). In this simplified case, the Relying Party trusts that the Attester cannot be meaningfully changed from the outside during any reportable interval. Based on that assumption, and when this is the case then the step of the Relying Party PoF can be safely omitted.

In all cases, appraisal policies define the conditions and prerequisites for when an Attester does qualify for secure interactions. To qualify, an Attester has to be able to provide all of the mandatory affirming Trustworthiness Claims and identities needed by a Relying Party’s Appraisal Policy for Attestation Results, and none of the disqualifying detraction Trustworthiness Claims.

More details on each interaction step of Below Zero Trust are as follows. The numbers used in this sequence match to the numbered steps in Figure 1:

1. An Attester sends Evidence which is provably fresh to Verifier A at time(EG). Freshness from the perspective of Verifier A MAY be established with Verifier PoF such as a nonce.

2. Verifier A appraises (1), then sends the following items back to that Attester within Attestation Results:
   1. the verified identity of the Attesting Environment,
   2. the Verifier A appraised Trustworthiness Vector of an Attester,
   3. a freshness proof associated with the Attestation Results,
   4. a Verifier signature across (2.1) though (2.3).

3. At time(EG’) a Relying Party PoF (such as a nonce) known to the Relying Party is sent to the Attester.

4. The Attester generates and sends AR-augmented Evidence to the Relying Party/Verifier B. This AR-augmented Evidence includes:
1. The Attestation Results from (2)

2. Any (optionally) new incremental Evidence from the Attesting Environment

3. Attestation Environment signature which spans a hash of the Attestation Results (such as the signature of (2.4)), the proof-of-freshness from (3), and (4.2). Note: this construct allows the delta of time between (2.3) and (3) to be definitively calculated by the Relying Party.

5. On receipt of (4), the Relying Party applies its Appraisal Policy for Attestation Results. At minimum, this appraisal policy process must include the following:

1. Verify that (4.3) includes the nonce from (3).

2. Use a local certificate to validate the signature (4.1).

3. Verify that the hash from (4.3) matches (4.1)

4. Use the identity of (2.1) to validate the signature of (4.3).

5. Failure of any steps (5.1) through (5.4) means the link does not meet minimum validation criteria, therefore appraise the link as having a null Verifier B Trustworthiness Vector. Jump to step (6.1).

6. When there is large or uncertain time gap between time(EG) and time(EG'), the link should be assigned a null Verifier B Trustworthiness Vector. Jump to step (6.1).

7. Assemble the Verifier B Trustworthiness Vector

   1. Copy Verifier A Trustworthiness Vector to Verifier B Trustworthiness Vector

   2. Add implicit Trustworthiness Claims inherent to the type of TEE.

   3. Prune any Trustworthiness Claims unsupportable by the Attesting Environment.

   4. Prune any Trustworthiness Claims the Relying Party doesn’t accept from this Verifier.
6. The Relying Party takes action based on Verifier B’s appraised Trustworthiness Vector, and applies the Appraisal Policy for Attestation Results. Following is a reasonable process for such evaluation:

1. Prune any Trustworthiness Claims from the Trustworthiness Vector not used in the Appraisal Policy for Attestation Results.

2. Allow the information exchange from the Attester into a Relying Party context in the Appraisal Policy for Attestation Results where the Verifier B appraised Trustworthiness Vector includes all the mandatory Trustworthiness Claims are in the "Affirming" value range, and none of the disqualifying Trustworthiness Claims are in the "Contraindicated" value range.

3. Disallow any information exchange into a Relying Party context for which that Verifier B appraised Trustworthiness Vector is not qualified.

As link layer protocols re-authenticate, steps (1) to (2) and steps (3) to (6) will independently refresh. This allows the Trustworthiness of Attester to be continuously re-appraised. There are only specific event triggers which will drive the refresh of Evidence generation (1), Attestation Result generation (2), or AR-augmented Evidence generation (4):

* life-cycle events, e.g. a change to an Authentication Secret of the Attester or an update of a software component.

* uptime-cycle events, e.g. a hard reset or a re-initialization of an Attester.

* authentication-cycle events, e.g. a link-layer interface reset could result in a new (4).

3.3. Mutual Attestation

In the interaction models described above, each device on either side of a secure interaction may require remote attestation of its peer. This process is known as mutual-attestation. To support mutual-attestation, the interaction models listed above may be run independently on either side of the connection.
3.4. Transport Protocol Integration

Either unidirectional attestation or mutual attestation may be supported within the protocol interactions needed for the establishment of a single transport session. While this document does not mandate specific transport protocols, messages containing the Attestation Results and AR Augmented Evidence can be passed within an authentication framework such as the EAP protocol [RFC5247] over TLS [RFC8446].

Appendix A. Implementation Guidance

A.1. Supplementing Trustworthiness Claims

What has been encoded into each Trustworthiness Claim is the domain of integer values which is likely to drive a different programmatic decision in the Relying Party’s Appraisal Policy for Attestation Results. This will not be the only thing a Relying Party’s Operations team might care to track for measurement or debugging purposes.

There is also the opportunity for the Verifier to include supplementary Evidence beyond a set of asserted Trustworthiness Claims. It is recommended that if supplementary Evidence is provided by the Verifier within the Attestation Results, that this supplementary Evidence includes a reference to a specific Trustworthiness Claim. This will allow a deeper understanding of some of the reasoning behind the integer value assigned.

Appendix B. Supportable Trustworthiness Claims

The following is a table which shows what Claims are supportable by different Attesting Environment types. Note that claims MAY BE implicit to an Attesting Environment type, and therefore do not have to be included in the Trustworthiness Vector to be considered as set by the Relying Party.
B.1. Supportable Trustworthiness Claims for HSM-based CC

Following are Trustworthiness Claims which MAY be set for a HSM-based Confidential Computing Attester. (Such as a TPM [TPM-ID].)
<table>
<thead>
<tr>
<th>Trustworthiness Claim</th>
<th>Required?</th>
<th>Appraisal Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration</td>
<td>Optional</td>
<td>Verifier evaluation of Attester reveals no configuration lines which expose the Attester to known security vulnerabilities. This may be done with or without the involvement of a TPM PCR.</td>
</tr>
<tr>
<td>executables</td>
<td>Yes</td>
<td>Checks the TPM PCRs for the static operating system, and for any tracked files subsequently loaded</td>
</tr>
<tr>
<td>file-system</td>
<td>No</td>
<td>Can be supported, but TPM tracking is unlikely</td>
</tr>
<tr>
<td>hardware</td>
<td>Yes</td>
<td>If TPM PCR check ok from BIOS checks, through Master Boot Record configuration</td>
</tr>
<tr>
<td>instance-identity</td>
<td>Optional</td>
<td>Check IDevID</td>
</tr>
<tr>
<td>runtime-opaque</td>
<td>n/a</td>
<td>TPMs are not recommended to provide a sufficient technology base for this Trustworthiness Claim.</td>
</tr>
<tr>
<td>sourced-data</td>
<td>n/a</td>
<td>TPMs are not recommended to provide a sufficient technology base for this Trustworthiness Claim.</td>
</tr>
<tr>
<td>storage-opaque</td>
<td>Minimal</td>
<td>With a TPM, secure storage space exists and is writeable by external applications. But the space is so limited that it often is used just be used to store keys.</td>
</tr>
</tbody>
</table>

Setting the Trustworthiness Claims may follow the following logic at the Verifier A within (2) of Figure 1:
Start: Evidence received starts the generation of a new Trustworthiness Vector. (e.g., TPM Quote Received, log received, or appraisal timer expired)

Step 0: set Trustworthiness Vector = Null

Step 1: Is there sufficient fresh signed evidence to appraise?
   (yes) - No Action
   (no) - Goto Step 6

Step 2: Appraise Hardware Integrity PCRs
   if (hardware NOT "0") - push onto vector
   if (hardware NOT affirming or warning), go to Step 6

Step 3: Appraise Attesting Environment identity
   if (instance-identity <> "0") - push onto vector

Step 4: Appraise executable loaded and filesystem integrity
   if (executables NOT "0") - push onto vector
   if (executables NOT affirming or warning), go to Step 6

Step 5: Appraise all remaining Trustworthiness Claims Independently and set as appropriate.

Step 6: Assemble Attestation Results, and push to Attester

End

B.2. Supportable Trustworthiness Claims for process-based CC

Following are Trustworthiness Claims which MAY be set for a process-based Confidential Computing based Attester. (Such as a SGX Enclaves and TrustZone.)
<table>
<thead>
<tr>
<th>Trustworthiness Claim</th>
<th>Required?</th>
<th>Appraisal Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance-identity</td>
<td>Optional</td>
<td>Internally available in TEE. But keys might not be known/exposed to the Relying Party by the Attesting Environment.</td>
</tr>
<tr>
<td>configuration</td>
<td>Optional</td>
<td>If done, this is at the Application Layer. Plus each process needs its own protection mechanism as the protection is limited to the process itself.</td>
</tr>
<tr>
<td>executables</td>
<td>Optional</td>
<td>Internally available in TEE. But keys might not be known/exposed to the Relying Party by the Attesting Environment.</td>
</tr>
<tr>
<td>file-system</td>
<td>Optional</td>
<td>Can be supported by application, but process-based CC is not a sufficient technology base for this Trustworthiness Claim.</td>
</tr>
<tr>
<td>hardware</td>
<td>Implicit in signature</td>
<td>At least the TEE is protected here. Other elements of the system outside of the TEE might need additional protections if used by the application process.</td>
</tr>
<tr>
<td>runtime-opaque</td>
<td>Implicit in signature</td>
<td>From the TEE</td>
</tr>
<tr>
<td>storage-opaque</td>
<td>Implicit in signature</td>
<td>Although the application must assert that this function is used by the code itself.</td>
</tr>
<tr>
<td>sourced-data</td>
<td>Optional</td>
<td>Will need to be supported by application code</td>
</tr>
</tbody>
</table>

Table 3
### B.3. Supportable Trustworthiness Claims for VM-based CC

Following are Trustworthiness Claims which MAY be set for a VM-based Confidential Computing based Attester. (Such as SEV, TDX, ACCA, SEV-SNP.)

<table>
<thead>
<tr>
<th>Trustworthiness Claim</th>
<th>Required?</th>
<th>Appraisal Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance-identity</td>
<td>Optional</td>
<td>Internally available in TEE. But keys might not be known/ exposed to the Relying Party by the Attesting Environment.</td>
</tr>
<tr>
<td>configuration</td>
<td>Optional</td>
<td>Requires application integration. Easier than with process-based solution, as the whole protected machine can be evaluated.</td>
</tr>
<tr>
<td>executables</td>
<td>Optional</td>
<td>Internally available in TEE. But keys might not be known/ exposed to the Relying Party by the Attesting Environment.</td>
</tr>
<tr>
<td>file-system</td>
<td>Optional</td>
<td>Can be supported by application</td>
</tr>
<tr>
<td>hardware</td>
<td>Chip dependent</td>
<td>At least the TEE is protected here. Other elements of the system outside of the TEE might need additional protections is used by the application process.</td>
</tr>
<tr>
<td>runtime-opaque</td>
<td>Implicit in signature</td>
<td>From the TEE</td>
</tr>
<tr>
<td>storage-opaque</td>
<td>Chip dependent</td>
<td>Although the application must assert that this function is used by the code itself.</td>
</tr>
<tr>
<td>sourced-data</td>
<td>Optional</td>
<td>Will need to be supported by application code</td>
</tr>
</tbody>
</table>

Table 4
Appendix C.  Some issues being worked

It is possible for a cluster/hierarchy of Verifiers to have aggregate AR which are perhaps signed/endorsed by a lead Verifier. What should be the Proof-of-Freshness or Verifier associated with any of the aggregate set of Trustworthiness Claims?

There will need to be a subsequent document which documents how these objects which will be translated into a protocol on a wire (e.g. EAP on TLS). Some breakpoint between what is in this draft, and what is in specific drafts for wire encoding will need to be determined. Questions like architecting the cluster/hierarchy of Verifiers fall into this breakdown.

For some Trustworthiness Claims, there could be value in identifying a specific Appraisal Policy for Attestation Results applied within the Attester. One way this could be done would be a URI which identifies the policy used at Verifier A, and this URI would reference a specific Trustworthiness Claim. As the URI also could encode the version of the software, it might also act as a mechanism to signal the Relying Party to refresh/re-evaluate its view of Verifier A. Do we need this type of structure to be included here? Should it be in subsequent documents?

Expand the variant of Figure 1 which requires no Relying Party PoF into its own picture.

In what document (if any) do we attempt normalization of the identity claims between different types of TEE. E.g., does MRSIGNER plus extra loaded software = the sum of TrustZone Signer IDs for loaded components?

Remote Attestation Procedures Architecture
draft-ietf-rats-architecture-15

Abstract

In network protocol exchanges it is often useful for one end of a communication to know whether the other end is in an intended operating state. This document provides an architectural overview of the entities involved that make such tests possible through the process of generating, conveying, and evaluating evidentiary claims. An attempt is made to provide for a model that is neutral toward processor architectures, the content of claims, and protocols.

Note to Readers

Discussion of this document takes place on the RATS Working Group mailing list (rats@ietf.org), which is archived at https://mailarchive.ietf.org/arch/browse/rats/ (https://mailarchive.ietf.org/arch/browse/rats/).

Source for this draft and an issue tracker can be found at https://github.com/ietf-rats-wg/architecture (https://github.com/ietf-rats-wg/architecture).

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.
Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 12 August 2022.

1. Introduction

The question of how one system can know that another system can be trusted has found new interest and relevance in a world where trusted computing elements are maturing in processor architectures.
Systems that have been attested and verified to be in a good state (for some value of "good") can improve overall system posture. Conversely, systems that cannot be attested and verified to be in a good state can be given reduced access or privileges, taken out of service, or otherwise flagged for repair.

For example:

* A bank back-end system might refuse to transact with another system that is not known to be in a good state.

* A healthcare system might refuse to transmit electronic healthcare records to a system that is not known to be in a good state.

In Remote Attestation Procedures (RATS), one peer (the "Attester") produces believable information about itself - Evidence - to enable a remote peer (the "Relying Party") to decide whether to consider that Attester a trustworthy peer or not. RATS are facilitated by an additional vital party, the Verifier.

The Verifier appraises Evidence via appraisal policies and creates the Attestation Results to support Relying Parties in their decision process. This document defines a flexible architecture consisting of attestation roles and their interactions via conceptual messages. Additionally, this document defines a universal set of terms that can be mapped to various existing and emerging Remote Attestation Procedures. Common topological patterns and the sequence of data flows associated with them, such as the "Passport Model" and the "Background-Check Model", are illustrated. The purpose is to define useful terminology for remote attestation and enable readers to map their solution architecture to the canonical attestation architecture provided here. Having a common terminology that provides well-understood meanings for common themes such as roles, device composition, topological patterns, and appraisal procedures is vital for semantic interoperability across solutions and platforms involving multiple vendors and providers.

Amongst other things, this document is about trust and trustworthiness. Trust is a choice one makes about another system. Trustworthiness is a quality about the other system that can be used in making one’s decision to trust it or not. This is subtle difference and being familiar with the difference is crucial for using this document. Additionally, the concepts of freshness and trust relationships with respect to RATS are elaborated on to enable implementers to choose appropriate solutions to compose their Remote Attestation Procedures.
2. Reference Use Cases

This section covers a number of representative and generic use cases for remote attestation, independent of specific solutions. The purpose is to provide motivation for various aspects of the architecture presented in this document. Many other use cases exist, and this document does not intend to have a complete list, only to illustrate a set of use cases that collectively cover all the functionality required in the architecture.

Each use case includes a description followed by an additional summary of the Attester and Relying Party roles derived from the use case.

2.1. Network Endpoint Assessment

Network operators want trustworthy reports that include identity and version information about the hardware and software on the machines attached to their network. Examples of reports include purposes, such as inventory summaries, audit results, anomaly notifications, typically including the maintenance of log records or trend reports. The network operator may also want a policy by which full access is only granted to devices that meet some definition of hygiene, and so wants to get Claims about such information and verify its validity. Remote attestation is desired to prevent vulnerable or compromised devices from getting access to the network and potentially harming others.

Typically, a trustworthy solution starts with a specific component (sometimes referred to as a root of trust) that often provides trustworthy device identity, and performs a series of operations that enables trustworthiness appraisals for other components. Such components perform operations that help determine the trustworthiness of yet other components, by collecting, protecting or signing measurements. Measurements that have been signed by such components comprise Evidence that when evaluated either supports or refutes a claim of trustworthiness. Measurements can describe a variety of attributes of system components, such as hardware, firmware, BIOS, software, etc.

Attester: A device desiring access to a network.

Relying Party: Network equipment such as a router, switch, or access point, responsible for admission of the device into the network.
2.2. Confidential Machine Learning Model Protection

A device manufacturer wants to protect its intellectual property. The intellectual property's scope primarily encompasses the machine learning (ML) model that is deployed in the devices purchased by its customers. The protection goals include preventing attackers, potentially the customer themselves, from seeing the details of the model.

This typically works by having some protected environment in the device go through a remote attestation with some manufacturer service that can assess its trustworthiness. If remote attestation succeeds, then the manufacturer service releases either the model, or a key to decrypt a model already deployed on the Attester in encrypted form, to the requester.

Attester: A device desiring to run an ML model.

Relying Party: A server or service holding ML models it desires to protect.

2.3. Confidential Data Protection

This is a generalization of the ML model use case above, where the data can be any highly confidential data, such as health data about customers, payroll data about employees, future business plans, etc. As part of the attestation procedure, an assessment is made against a set of policies to evaluate the state of the system that is requesting the confidential data. Attestation is desired to prevent leaking data via compromised devices.

Attester: An entity desiring to retrieve confidential data.

Relying Party: An entity that holds confidential data for release to authorized entities.

2.4. Critical Infrastructure Control

Potentially harmful physical equipment (e.g., power grid, traffic control, hazardous chemical processing, etc.) is connected to a network in support of critical infrastructure. The organization managing such infrastructure needs to ensure that only authorized code and users can control corresponding critical processes, and that these processes are protected from unauthorized manipulation or other threats. When a protocol operation can affect a critical system component of the infrastructure, devices attached to that critical component require some assurances depending on the security context, including that: a requesting device or application has not been
compromised, and the requesters and actors act on applicable policies. As such, remote attestation can be used to only accept commands from requesters that are within policy.

Attester: A device or application wishing to control physical equipment.

Relying Party: A device or application connected to potentially dangerous physical equipment (hazardous chemical processing, traffic control, power grid, etc.).

2.5. Trusted Execution Environment Provisioning

A Trusted Application Manager (TAM) server is responsible for managing the applications running in a Trusted Execution Environment (TEE) of a client device, as described in [I-D.ietf-teep-architecture]. To achieve its purpose, the TAM needs to assess the state of a TEE, or of applications in the TEE, of a client device. The TEE conducts Remote Attestation Procedures with the TAM, which can then decide whether the TEE is already in compliance with the TAM’s latest policy. If not, the TAM has to uninstall, update, or install approved applications in the TEE to bring it back into compliance with the TAM’s policy.

Attester: A device with a TEE capable of running trusted applications that can be updated.

Relying Party: A TAM.

2.6. Hardware Watchdog

There is a class of malware that holds a device hostage and does not allow it to reboot to prevent updates from being applied. This can be a significant problem, because it allows a fleet of devices to be held hostage for ransom.

A solution to this problem is a watchdog timer implemented in a protected environment such as a Trusted Platform Module (TPM), as described in [TCGarch] section 43.3. If the watchdog does not receive regular, and fresh, Attestation Results as to the system’s health, then it forces a reboot.

Attester: The device that should be protected from being held hostage for a long period of time.

Relying Party: A watchdog capable of triggering a procedure that resets a device into a known, good operational state.
2.7. FIDO Biometric Authentication

In the Fast IDentity Online (FIDO) protocol [WebAuthN], [CTAP], the device in the user's hand authenticates the human user, whether by biometrics (such as fingerprints), or by PIN and password. FIDO authentication puts a large amount of trust in the device compared to typical password authentication because it is the device that verifies the biometric, PIN and password inputs from the user, not the server. For the Relying Party to know that the authentication is trustworthy, the Relying Party needs to know that the Authenticator part of the device is trustworthy. The FIDO protocol employs remote attestation for this.

The FIDO protocol supports several remote attestation protocols and a mechanism by which new ones can be registered and added. Remote attestation defined by RATS is thus a candidate for use in the FIDO protocol.

Attester: FIDO Authenticator.

Relying Party: Any web site, mobile application back-end, or service that relies on authentication data based on biometric information.

3. Architectural Overview

Figure 1 depicts the data that flows between different roles, independent of protocol or use case.
The text below summarizes the activities conducted by the roles illustrated in Figure 1. Roles are assigned to entities. Entities are often system components [RFC4949], such as devices. As the term device is typically more intuitive than the term entity or system component, device is often used as a illustrative synonym throughout this document.

The Attester role is assigned to entities that create Evidence that is conveyed to a Verifier.

The Verifier role is assigned to entities that use the Evidence, any Reference Values from Reference Value Providers, and any Endorsements from Endorsers, by applying an Appraisal Policy for Evidence to assess the trustworthiness of the Attester. This procedure is called the appraisal of Evidence.

Subsequently, the Verifier role generates Attestation Results for use by Relying Parties.
The Appraisal Policy for Evidence might be obtained from the Verifier Owner via some protocol mechanism, or might be configured into the Verifier by the Verifier Owner, or might be programmed into the Verifier, or might be obtained via some other mechanism.

The Relying Party role is assigned to entities that uses Attestation Results by applying its own appraisal policy to make application-specific decisions, such as authorization decisions. This procedure is called the appraisal of Attestation Results.

The Appraisal Policy for Attestation Results might be obtained from the Relying Party Owner via some protocol mechanism, or might be configured into the Relying Party by the Relying Party Owner, or might be programmed into the Relying Party, or might be obtained via some other mechanism.

See Section 8 for further discussion of the conceptual messages shown in Figure 1. Section Section 4 provides a more complete definition of all RATS roles.

3.1. Two Types of Environments of an Attester

As shown in Figure 2, an Attester consists of at least one Attesting Environment and at least one Target Environment co-located in one entity. In some implementations, the Attesting and Target Environments might be combined into one environment. Other implementations might have multiple Attesting and Target Environments, such as in the examples described in more detail in Section 3.2 and Section 3.3. Other examples may exist. All compositions of Attesting and Target Environments discussed in this architecture can be combined into more complex implementations.
Claims are collected from Target Environments. That is, Attesting Environments collect the values and the information to be represented in Claims, by reading system registers and variables, calling into subsystems, taking measurements on code, memory, or other security related assets of the Target Environment. Attesting Environments then format the Claims appropriately, and typically use key material and cryptographic functions, such as signing or cipher algorithms, to generate Evidence. There is no limit to or requirement on the types of hardware or software environments that can be used to implement an Attesting Environment, for example: Trusted Execution Environments (TEEs), embedded Secure Elements (eSEs), Trusted Platform Modules (TPMs) [TCGarch], or BIOS firmware.

An arbitrary execution environment may not, by default, be capable of Claims collection for a given Target Environment. Execution environments that are designed specifically to be capable of Claims collection are referred to in this document as Attesting Environments. For example, a TPM doesn’t actively collect Claims
itself, it instead requires another component to feed various values to the TPM. Thus, an Attesting Environment in such a case would be the combination of the TPM together with whatever component is feeding it the measurements.

### 3.2. Layered Attestation Environments

By definition, the Attester role generates Evidence. An Attester may consist of one or more nested environments (layers). The bottom layer of an Attester has an Attesting Environment that is typically designed to be immutable or difficult to modify by malicious code. In order to appraise Evidence generated by an Attester, the Verifier needs to trust various layers, including the bottom Attesting Environment. Trust in the Attester’s layers, including the bottom layer, can be established in various ways as discussed in Section 7.4.

In layered attestation, Claims can be collected from or about each layer beginning with an initial layer. The corresponding Claims can be structured in a nested fashion that reflects the nesting of the Attester’s layers. Normally, Claims are not self-asserted, rather a previous layer acts as the Attesting Environment for the next layer. Claims about an initial layer typically are asserted by an Endorser.

The example device illustrated in Figure 3 includes (A) a BIOS stored in read-only memory, (B) a bootloader, and (C) an operating system kernel.
Figure 3: Layered Attester
The first Attesting Environment, the ROM in this example, has to ensure the integrity of the bootloader (the first Target Environment). There are potentially multiple kernels to boot, and the decision is up to the bootloader. Only a bootloader with intact integrity will make an appropriate decision. Therefore, the Claims relating to the integrity of the bootloader have to be measured securely. At this stage of the boot-cycle of the device, the Claims collected typically cannot be composed into Evidence.

After the boot sequence is started, the BIOS conducts the most important and defining feature of layered attestation, which is that the successfully measured bootloader now becomes (or contains) an Attesting Environment for the next layer. This procedure in layered attestation is sometimes called "staging". It is important that the bootloader not be able to alter any Claims about itself that were collected by the BIOS. This can be ensured having those Claims be either signed by the BIOS or stored in a tamper-proof manner by the BIOS.

Continuing with this example, the bootloader’s Attesting Environment is now in charge of collecting Claims about the next Target Environment, which in this example is the kernel to be booted. The final Evidence thus contains two sets of Claims: one set about the bootloader as measured and signed by the BIOS, plus a set of Claims about the kernel as measured and signed by the bootloader.

This example could be extended further by making the kernel become another Attesting Environment for an application as another Target Environment. This would result in a third set of Claims in the Evidence pertaining to that application.

The essence of this example is a cascade of staged environments. Each environment has the responsibility of measuring the next environment before the next environment is started. In general, the number of layers may vary by device or implementation, and an Attesting Environment might even have multiple Target Environments that it measures, rather than only one as shown by example in Figure 3.

3.3. Composite Device

A composite device is an entity composed of multiple sub-entities such that its trustworthiness has to be determined by the appraisal of all these sub-entities.

Each sub-entity has at least one Attesting Environment collecting the Claims from at least one Target Environment, then this sub-entity generates Evidence about its trustworthiness. Therefore, each sub-
entity can be called an Attester. Among all the Attesters, there may be only some which have the ability to communicate with the Verifier while others do not.

For example, a carrier-grade router consists of a chassis and multiple slots. The trustworthiness of the router depends on all its slots' trustworthiness. Each slot has an Attesting Environment, such as a TEE, collecting the Claims of its boot process, after which it generates Evidence from the Claims.

Among these slots, only a "main" slot can communicate with the Verifier while other slots cannot. But other slots can communicate with the main slot by the links between them inside the router. So the main slot collects the Evidence of other slots, produces the final Evidence of the whole router and conveys the final Evidence to the Verifier. Therefore the router is a composite device, each slot is an Attester, and the main slot is the lead Attester.

Another example is a multi-chassis router composed of multiple single carrier-grade routers. Multi-chassis router setups create redundancy groups that provide higher throughput by interconnecting multiple routers in these groups, which can be treated as one logical router for simpler management. A multi-chassis router setup provides a management point that connects to the Verifier. Typically one router in the group is designated as the main router. Other routers in the multi-chassis setup are connected to the main router only via physical network links and are therefore managed and appraised via the main router’s help. Consequently, a multi-chassis router setup is a composite device, each router is an Attester, and the main router is the lead Attester.

Figure 4 depicts the conceptual data flow for a composite device.
In a composite device, each Attester generates its own Evidence by its Attesting Environment(s) collecting the Claims from its Target Environment(s). The lead Attester collects Evidence from other Attesters and conveys it to a Verifier. Collection of Evidence from sub-entities may itself be a form of Claims collection that results in Evidence asserted by the lead Attester. The lead Attester generates Evidence about the layout of the whole composite device, while sub-Attesters generate Evidence about their respective (sub-)modules.

In this scenario, the trust model described in Section 7 can also be applied to an inside Verifier.

3.4. Implementation Considerations

An entity can take on multiple RATS roles (e.g., Attester, Verifier, Relying Party, etc.) at the same time. Multiple entities can cooperate to implement a single RATS role as well. In essence, the combination of roles and entities can be arbitrary. For example, in the composite device scenario, the entity inside the lead Attester can also take on the role of a Verifier, and the outer entity of
Verifier can take on the role of a Relying Party. After collecting the Evidence of other Attesters, this inside Verifier uses Endorsements and appraisal policies (obtained the same way as by any other Verifier) as part of the appraisal procedures that generate Attestation Results. The inside Verifier then conveys the Attestation Results of other Attesters to the outside Verifier, whether in the same conveyance protocol as part of the Evidence or not.

4. Terminology

This document uses the following terms.

4.1. Roles

Attester: A role performed by an entity (typically a device) whose Evidence must be appraised in order to infer the extent to which the Attester is considered trustworthy, such as when deciding whether it is authorized to perform some operation.

Produces: Evidence

Relying Party: A role performed by an entity that depends on the validity of information about an Attester, for purposes of reliably applying application specific actions. Compare /relying party/ in [RFC4949].

Consumes: Attestation Results, Appraisal Policy for Attestation Results

Verifier: A role performed by an entity that appraises the validity of Evidence about an Attester and produces Attestation Results to be used by a Relying Party.

Consumes: Evidence, Reference Values, Endorsements, Appraisal Policy for Evidence

Produces: Attestation Results

Relying Party Owner: A role performed by an entity (typically an administrator), that is authorized to configure Appraisal Policy for Attestation Results in a Relying Party.

Produces: Appraisal Policy for Attestation Results

Verifier Owner: A role performed by an entity (typically an administrator), that is authorized to configure Appraisal Policy for Evidence in a Verifier.
Produces: Appraisal Policy for Evidence

Endorser: A role performed by an entity (typically a manufacturer) whose Endorsements may help Verifiers appraise the authenticity of Evidence and infer further capabilities of the Attester.

Produces: Endorsements

Reference Value Provider: A role performed by an entity (typically a manufacturer) whose Reference Values help Verifiers appraise Evidence to determine if acceptable known Claims have been recorded by the Attester.

Produces: Reference Values

4.2. Artifacts

Claim: A piece of asserted information, often in the form of a name/value pair. Claims make up the usual structure of Evidence and other RATS artifacts. Compare /claim/ in [RFC7519].

Endorsement: A secure statement that an Endorser vouches for the integrity of an Attester's various capabilities such as Claims collection and Evidence signing.

Consumed By: Verifier

Produced By: Endorser

Evidence: A set of Claims generated by an Attester to be appraised by a Verifier. Evidence may include configuration data, measurements, telemetry, or inferences.

Consumed By: Verifier

Produced By: Attester

Attestation Result: The output generated by a Verifier, typically including information about an Attester, where the Verifier vouches for the validity of the results.

Consumed By: Relying Party

Produced By: Verifier

Consumed By: Verifier

Produced By: Verifier Owner

Appraisal Policy for Attestation Results: A set of rules that direct how a Relying Party uses the Attestation Results regarding an Attester generated by the Verifiers. Compare /security policy/ in [RFC4949].

Consumed by: Relying Party

Produced by: Relying Party Owner

Reference Values: A set of values against which values of Claims can be compared as part of applying an Appraisal Policy for Evidence. Reference Values are sometimes referred to in other documents as known-good values, golden measurements, or nominal values, although those terms typically assume comparison for equality, whereas here Reference Values might be more general and be used in any sort of comparison.

Consumed By: Verifier

Produced By: Reference Value Provider

5. Topological Patterns

Figure 1 shows a data-flow diagram for communication between an Attester, a Verifier, and a Relying Party. The Attester conveys its Evidence to the Verifier for appraisal, and the Relying Party receives the Attestation Result from the Verifier. This section refines the data-flow diagram by describing two reference models, as well as one example composition thereof. The discussion that follows is for illustrative purposes only and does not constrain the interactions between RATS roles to the presented patterns.

5.1. Passport Model

The passport model is so named because of its resemblance to how nations issue passports to their citizens. The nature of the Evidence that an individual needs to provide to its local authority is specific to the country involved. The citizen retains control of the resulting passport document and presents it to other entities when it needs to assert a citizenship or identity Claim, such as an airport immigration desk. The passport is considered sufficient because it vouches for the citizenship and identity Claims, and it is issued by a trusted authority. Thus, in this immigration desk analogy, the citizen is the Attester, the passport issuing agency is
a Verifier, the passport application and identifying information (e.g., birth certificate) is the Evidence, the passport is an Attestation Result, and the immigration desk is a Relying Party.

In this model, an Attester conveys Evidence to a Verifier, which compares the Evidence against its appraisal policy. The Verifier then gives back an Attestation Result which the Attester treats as opaque data. The Attester does not consume the Attestation Result, but might cache it. The Attester can then present the Attestation Result (and possibly additional Claims) to a Relying Party, which then compares this information against its own appraisal policy.

Three ways in which the process may fail include:

* First, the Verifier may not issue a positive Attestation Result due to the Evidence not passing the Appraisal Policy for Evidence.

* The second way in which the process may fail is when the Attestation Result is examined by the Relying Party, and based upon the Appraisal Policy for Attestation Results, the result does not pass the policy.

* The third way is when the Verifier is unreachable or unavailable.

As with any other information needed by the Relying Party to make an authorization decision, an Attestation Result can be carried in a resource access protocol between the Attester and Relying Party. In this model the details of the resource access protocol constrain the serialization format of the Attestation Result. The format of the Evidence on the other hand is only constrained by the Attester-Verifier remote attestation protocol. This implies that interoperability and standardization is more relevant for Attestation Results than it is for Evidence.
5.2. Background-Check Model

The background-check model is so named because of the resemblance of how employers and volunteer organizations perform background checks. When a prospective employee provides Claims about education or previous experience, the employer will contact the respective institutions or former employers to validate the Claim. Volunteer organizations often perform police background checks on volunteers in order to determine the volunteer’s trustworthiness. Thus, in this analogy, a prospective volunteer is an Attester, the organization is the Relying Party, and the organization that issues a report is a Verifier.

In this model, an Attester conveys Evidence to a Relying Party, which treats it as opaque and simply forwards it on to a Verifier. The Verifier compares the Evidence against its appraisal policy, and returns an Attestation Result to the Relying Party. The Relying Party then compares the Attestation Result against its own appraisal policy.

The resource access protocol between the Attester and Relying Party includes Evidence rather than an Attestation Result, but that Evidence is not processed by the Relying Party. Since the Evidence is merely forwarded on to a trusted Verifier, any serialization format can be used for Evidence because the Relying Party does not need a parser for it. The only requirement is that the Evidence can be _encapsulated in_ the format required by the resource access protocol between the Attester and Relying Party.

However, like in the Passport model, an Attestation Result is still consumed by the Relying Party. Code footprint and attack surface area can be minimized by using a serialization format for which the Relying Party already needs a parser to support the protocol between the Attester and Relying Party, which may be an existing standard or widely deployed resource access protocol. Such minimization is especially important if the Relying Party is a constrained node.
5.3. Combinations

One variation of the background-check model is where the Relying Party and the Verifier are on the same machine, performing both functions together. In this case, there is no need for a protocol between the two.

It is also worth pointing out that the choice of model depends on the use case, and that different Relying Parties may use different topological patterns.

The same device may need to create Evidence for different Relying Parties and/or different use cases. For instance, it would use one model to provide Evidence to a network infrastructure device to gain access to the network, and the other model to provide Evidence to a server holding confidential data to gain access to that data. As such, both models may simultaneously be in use by the same device.

Figure 7 shows another example of a combination where Relying Party 1 uses the passport model, whereas Relying Party 2 uses an extension of the background-check model. Specifically, in addition to the basic functionality shown in Figure 6, Relying Party 2 actually provides the Attestation Result back to the Attester, allowing the Attester to use it with other Relying Parties. This is the model that the Trusted Application Manager plans to support in the TEEP architecture [I-D.ietf-teep-architecture].
6. Roles and Entities

An entity in the RATS architecture includes at least one of the roles defined in this document.

An entity can aggregate more than one role into itself, such as being both a Verifier and a Relying Party, or being both a Reference Value Provider and an Endorser. As such, any conceptual messages (see Section 8 for more discussion) originating from such roles might also be combined. For example, Reference Values might be conveyed as part of an appraisal policy if the Verifier Owner and Reference Value Provider roles are combined. Similarly, Reference Values might be conveyed as part of an Endorsement if the Endorser and Reference Value Provider roles are combined.

Interactions between roles aggregated into the same entity do not necessarily use the Internet Protocol. Such interactions might use a loopback device or other IP-based communication between separate environments, but they do not have to. Alternative channels to convey conceptual messages include function calls, sockets, GPIO interfaces, local busses, or hypervisor calls. This type of conveyance is typically found in composite devices. Most
importantly, these conveyance methods are out-of-scope of RATS, but they are presumed to exist in order to convey conceptual messages appropriately between roles.

In essence, an entity that combines more than one role creates and consumes the corresponding conceptual messages as defined in this document.

7. Trust Model

7.1. Relying Party

This document covers scenarios for which a Relying Party trusts a Verifier that can appraise the trustworthiness of information about an Attestor. Such trust is expressed by storing one or more "trust anchors" in a secure location known as a trust anchor store.

As defined in [RFC6024], "A trust anchor represents an authoritative entity via a public key and associated data. The public key is used to verify digital signatures, and the associated data is used to constrain the types of information for which the trust anchor is authoritative." The trust anchor may be a certificate or it may be a raw public key along with additional data if necessary such as its public key algorithm and parameters. In the context of this document, a trust anchor may also be a symmetric key, as in [TCG-DICE-SIBDA] or the symmetric mode described in [I-D.tschofenig-rats-ota-token].

Thus, trusting a Verifier might be expressed by having the Relying Party store the Verifier’s key or certificate in its trust anchor store, or might be expressed by storing the public key or certificate of an entity (e.g., a Certificate Authority) that is in the Verifier’s certificate path. For example, the Relying Party can verify that the Verifier is an expected one by out of band establishment of key material, combined with a protocol like TLS to communicate. There is an assumption that between the establishment of the trusted key material and the creation of the Evidence, that the Verifier has not been compromised.

For a stronger level of security, the Relying Party might require that the Verifier first provide information about itself that the Relying Party can use to assess the trustworthiness of the Verifier before accepting its Attestation Results. Such process would provide a stronger level of confidence in the correctness of the information provided, such as a belief that the authentic Verifier has not been compromised by malware.
For example, one explicit way for a Relying Party "A" to establish such confidence in the correctness of a Verifier "B", would be for B to first act as an Attester where A acts as a combined Verifier/ Relying Party. If A then accepts B as trustworthy, it can choose to accept B as a Verifier for other Attesters.

Similarly, the Relying Party also needs to trust the Relying Party Owner for providing its Appraisal Policy for Attestation Results, and in some scenarios the Relying Party might even require that the Relying Party Owner go through a remote attestation procedure with it before the Relying Party will accept an updated policy. This can be done similarly to how a Relying Party could establish trust in a Verifier as discussed above, i.e., verifying credentials against a trust anchor store and optionally requiring Attestation Results from the Relying Party Owner.

7.2. Attester

In some scenarios, Evidence might contain sensitive information such as Personally Identifiable Information (PII) or system identifiable information. Thus, an Attester must trust entities to which it conveys Evidence, to not reveal sensitive data to unauthorized parties. The Verifier might share this information with other authorized parties, according to a governing policy that address the handling of sensitive information (potentially included in Appraisal Policies for Evidence). In the background-check model, this Evidence may also be revealed to Relying Party(s).

When Evidence contains sensitive information, an Attester typically requires that a Verifier authenticates itself (e.g., at TLS session establishment) and might even request a remote attestation before the Attester sends the sensitive Evidence. This can be done by having the Attester first act as a Verifier/Relying Party, and the Verifier act as its own Attester, as discussed above.

7.3. Relying Party Owner

The Relying Party Owner might also require that the Relying Party first act as an Attester, providing Evidence that the Owner can appraise, before the Owner would give the Relying Party an updated policy that might contain sensitive information. In such a case, authentication or attestation in both directions might be needed, in which case typically one side’s Evidence must be considered safe to share with an untrusted entity, in order to bootstrap the sequence. See Section 11 for more discussion.
7.4. Verifier

The Verifier trusts (or more specifically, the Verifier’s security policy is written in a way that configures the Verifier to trust) a manufacturer, or the manufacturer’s hardware, so as to be able to appraise the trustworthiness of that manufacturer’s devices. Such trust is expressed by storing one or more trust anchors in the Verifier’s trust anchor store.

In a typical solution, a Verifier comes to trust an Attester indirectly by having an Endorser (such as a manufacturer) vouch for the Attester’s ability to securely generate Evidence through Endorsements (see Section 8.2). Endorsements might describe the ways in which the Attester resists attack, protects secrets and measures Target Environments. Consequently, the Endorser’s key material is stored in the Verifier’s trust anchor store so that Endorsements can be authenticated and used in the Verifier’s appraisal process.

In some solutions, a Verifier might be configured to directly trust an Attester by having the Verifier have the Attester’s key material (rather than the Endorser’s) in its trust anchor store.

Such direct trust must first be established at the time of trust anchor store configuration either by checking with an Endorser at that time, or by conducting a security analysis of the specific device. Having the Attester directly in the trust anchor store narrows the Verifier’s trust to only specific devices rather than all devices the Endorser might vouch for, such as all devices manufactured by the same manufacturer in the case that the Endorser is a manufacturer.

Such narrowing is often important since physical possession of a device can also be used to conduct a number of attacks, and so a device in a physically secure environment (such as one’s own premises) may be considered trusted whereas devices owned by others would not be. This often results in a desire to either have the owner run their own Endorser that would only endorse devices one owns, or to use Attesters directly in the trust anchor store. When there are many Attesters owned, the use of an Endorser enables better scalability.
That is, a Verifier might appraise the trustworthiness of an application component, operating system component, or service under the assumption that information provided about it by the lower-layer firmware or software is true. A stronger level of assurance of security comes when information can be vouched for by hardware or by ROM code, especially if such hardware is physically resistant to hardware tampering. In most cases, components that have to be vouched for via Endorsements because no Evidence is generated about them are referred to as roots of trust.

The manufacturer having arranged for an Attesting Environment to be provisioned with key material with which to sign Evidence, the Verifier is then provided with some way of verifying the signature on the Evidence. This may be in the form of an appropriate trust anchor, or the Verifier may be provided with a database of public keys (rather than certificates) or even carefully curated and secured lists of symmetric keys.

The nature of how the Verifier manages to validate the signatures produced by the Attester is critical to the secure operation of a remote attestation system, but is not the subject of standardization within this architecture.

A conveyance protocol that provides authentication and integrity protection can be used to convey Evidence that is otherwise unprotected (e.g., not signed). Appropriate conveyance of unprotected Evidence (e.g., [I-D.birkholz-rats-uccs]) relies on the following conveyance protocol’s protection capabilities:

1. The key material used to authenticate and integrity protect the conveyance channel is trusted by the Verifier to speak for the Attesting Environment(s) that collected Claims about the Target Environment(s).
2. All unprotected Evidence that is conveyed is supplied exclusively by the Attesting Environment that has the key material that protects the conveyance channel
3. A trusted environment protects the conveyance channel’s key material which may depend on other Attesting Environments with equivalent strength protections.

As illustrated in [I-D.birkholz-rats-uccs], an entity that receives unprotected Evidence via a trusted conveyance channel always takes on the responsibility of vouching for the Evidence’s authenticity and freshness. If protected Evidence is generated, the Attester’s Attesting Environments take on that responsibility. In cases where unprotected Evidence is processed by a Verifier, Relying Parties have
to trust that the Verifier is capable of handling Evidence in a manner that preserves the Evidence’s authenticity and freshness. Generating and conveying unprotected Evidence always creates significant risk and the benefits of that approach have to be carefully weighed against potential drawbacks.

See Section 12 for discussion on security strength.

7.5. Endorser, Reference Value Provider, and Verifier Owner

In some scenarios, the Endorser, Reference Value Provider, and Verifier Owner may need to trust the Verifier before giving the Endorsement, Reference Values, or appraisal policy to it. This can be done similarly to how a Relying Party might establish trust in a Verifier.

As discussed in Section 7.3, authentication or attestation in both directions might be needed, in which case typically one side’s identity or Evidence must be considered safe to share with an untrusted entity, in order to bootstrap the sequence. See Section 11 for more discussion.

8. Conceptual Messages

Figure 1 illustrates the flow of a conceptual messages between various roles. This section provides additional elaboration and implementation considerations. It is the responsibility of protocol specifications to define the actual data format and semantics of any relevant conceptual messages.

8.1. Evidence

Evidence is a set of Claims about the target environment that reveal operational status, health, configuration or construction that have security relevance. Evidence is appraised by a Verifier to establish its relevance, compliance, and timeliness. Claims need to be collected in a manner that is reliable such that a Target Environment cannot lie to the Attesting Environment about its trustworthiness properties. Evidence needs to be securely associated with the target environment so that the Verifier cannot be tricked into accepting Claims originating from a different environment (that may be more trustworthy). Evidence also must be protected from man-in-the-middle attackers who may observe, change or misdirect Evidence as it travels from Attester to Verifier. The timeliness of Evidence can be captured using Claims that pinpoint the time or interval when changes in operational status, health, and so forth occur.
8.2. Endorsements

An Endorsement is a secure statement that some entity (e.g., a manufacturer) vouches for the integrity of the device’s various capabilities such as claims collection, signing, launching code, transitioning to other environments, storing secrets, and more. For example, if the device’s signing capability is in hardware, then an Endorsement might be a manufacturer certificate that signs a public key whose corresponding private key is only known inside the device’s hardware. Thus, when Evidence and such an Endorsement are used together, an appraisal procedure can be conducted based on appraisal policies that may not be specific to the device instance, but merely specific to the manufacturer providing the Endorsement. For example, an appraisal policy might simply check that devices from a given manufacturer have information matching a set of Reference Values, or an appraisal policy might have a set of more complex logic on how to appraise the validity of information.

However, while an appraisal policy that treats all devices from a given manufacturer the same may be appropriate for some use cases, it would be inappropriate to use such an appraisal policy as the sole means of authorization for use cases that wish to constrain which compliant devices are considered authorized for some purpose. For example, an enterprise using remote attestation for Network Endpoint Assessment [RFC5209] may not wish to let every healthy laptop from the same manufacturer onto the network, but instead only want to let devices that it legally owns onto the network. Thus, an Endorsement may be helpful information in authenticating information about a device, but is not necessarily sufficient to authorize access to resources which may need device-specific information such as a public key for the device or component or user on the device.

8.3. Reference Values

Reference Values used in appraisal procedures come from a Reference Value Provider and are then used by the Verifier to compare to Evidence. Reference Values with matching Evidence produces acceptable Claims. Additionally, appraisal policy may play a role in determining the acceptance of Claims.

8.4. Attestation Results

Attestation Results are the input used by the Relying Party to decide the extent to which it will trust a particular Attester, and allow it to access some data or perform some operation.
Attestation Results may carry a boolean value indicating compliance or non-compliance with a Verifier’s appraisal policy, or may carry a richer set of Claims about the Attester, against which the Relying Party applies its Appraisal Policy for Attestation Results.

The quality of the Attestation Results depends upon the ability of the Verifier to evaluate the Attester. Different Attesters have a different _Strength of Function_ [strengthoffunction], which results in the Attestation Results being qualitatively different in strength.

An Attestation Result that indicates non-compliance can be used by an Attester (in the passport model) or a Relying Party (in the background-check model) to indicate that the Attester should not be treated as authorized and may be in need of remediation. In some cases, it may even indicate that the Evidence itself cannot be authenticated as being correct.

By default, the Relying Party does not believe the Attester to be compliant. Upon receipt of an authentic Attestation Result and given the Appraisal Policy for Attestation Results is satisfied, the Attester is allowed to perform the prescribed actions or access. The simplest such appraisal policy might authorize granting the Attester full access or control over the resources guarded by the Relying Party. A more complex appraisal policy might involve using the information provided in the Attestation Result to compare against expected values, or to apply complex analysis of other information contained in the Attestation Result.

Thus, Attestation Results can contain detailed information about an Attester, which can include privacy sensitive information as discussed in section Section 11. Unlike Evidence, which is often very device- and vendor-specific, Attestation Results can be vendor-neutral, if the Verifier has a way to generate vendor-agnostic information based on the appraisal of vendor-specific information in Evidence. This allows a Relying Party’s appraisal policy to be simpler, potentially based on standard ways of expressing the information, while still allowing interoperability with heterogeneous devices.

Finally, whereas Evidence is signed by the device (or indirectly by a manufacturer, if Endorsements are used), Attestation Results are signed by a Verifier, allowing a Relying Party to only need a trust relationship with one entity, rather than a larger set of entities, for purposes of its appraisal policy.
8.5. Appraisal Policies

The Verifier, when appraising Evidence, or the Relying Party, when appraising Attestation Results, checks the values of matched Claims against constraints specified in its appraisal policy. Examples of such constraints checking include:

* comparison for equality against a Reference Value, or
* a check for being in a range bounded by Reference Values, or
* membership in a set of Reference Values, or
* a check against values in other Claims.

Upon completing all appraisal policy constraints, the remaining Claims are accepted as input toward determining Attestation Results, when appraising Evidence, or as input to a Relying Party, when appraising Attestation Results.

9. Claims Encoding Formats

The following diagram illustrates a relationship to which remote attestation is desired to be added:

```
+-------------+               +------------+ Evaluate
|             |-------------->|            | request
|  Attester   |  Access some |   Relying  | against
|             |    resource  |    Party   | security
|             |              |              | policy

Figure 8: Typical Resource Access
```

In this diagram, the protocol between Attester and a Relying Party can be any new or existing protocol (e.g., HTTP(S), COAP(S), ROLIE [RFC8322], 802.1x, OPC UA [OPCUA], etc.), depending on the use case.

Typically, such protocols already have mechanisms for passing security information for authentication and authorization purposes. Common formats include JWTs [RFC7519], CWTs [RFC8392], and X.509 certificates.

Retrofitting already deployed protocols with remote attestation requires adding RATS conceptual messages to the existing data flows. This must be done in a way that does not degrade the security properties of the systems involved and should use native extension mechanisms provided by the underlying protocol. For example, if a TLS handshake is to be extended with remote attestation capabilities,
attestation Evidence may be embedded in an ad-hoc X.509 certificate extension (e.g., [TCG-DICE]), or into a new TLS Certificate Type (e.g., [I-D.tschofenig-tls-cwt]).

Especially for constrained nodes there is a desire to minimize the amount of parsing code needed in a Relying Party, in order to both minimize footprint and to minimize the attack surface. While it would be possible to embed a CWT inside a JWT, or a JWT inside an X.509 extension, etc., there is a desire to encode the information natively in a format that is already supported by the Relying Party.

This motivates having a common "information model" that describes the set of remote attestation related information in an encoding-agnostic way, and allowing multiple encoding formats (CWT, JWT, X.509, etc.) that encode the same information into the Claims format needed by the Relying Party.

The following diagram illustrates that Evidence and Attestation Results might be expressed via multiple potential encoding formats, so that they can be conveyed by various existing protocols. It also motivates why the Verifier might also be responsible for accepting Evidence that encodes Claims in one format, while issuing Attestation Results that encode Claims in a different format.

```

Figure 9: Multiple Attesters and Relying Parties with Different Formats
```
10. Freshness

A Verifier or Relying Party might need to learn the point in time (i.e., the "epoch") an Evidence or Attestation Result has been produced. This is essential in deciding whether the included Claims can be considered fresh, meaning they still reflect the latest state of the Attester, and that any Attestation Result was generated using the latest Appraisal Policy for Evidence.

This section provides a number of details. It does not however define any protocol formats, the interactions shown are abstract. This section is intended for those creating protocols and solutions to understand the options available to ensure freshness. The way in which freshness is provisioned in a protocol is an architectural decision. Provisioning of freshness has an impact on the number of needed round trips in a protocol, and therefore must be made very early in the design. Different decisions will have significant impacts on resulting interoperability, which is why this section goes into sufficient detail such that choices in freshness will be compatible across interacting protocols, such as depicted in Figure 9.

Freshness is assessed based on the Appraisal Policy for Evidence or Attestation Results that compares the estimated epoch against an "expiry" threshold defined locally to that policy. There is, however, always a race condition possible in that the state of the Attester, and the appraisal policies might change immediately after the Evidence or Attestation Result was generated. The goal is merely to narrow their recentness to something the Verifier (for Evidence) or Relying Party (for Attestation Result) is willing to accept. Some flexibility on the freshness requirement is a key component for enabling caching and reuse of both Evidence and Attestation Results, which is especially valuable in cases where their computation uses a substantial part of the resource budget (e.g., energy in constrained devices).

There are three common approaches for determining the epoch of Evidence or an Attestation Result.

10.1. Explicit Timekeeping using Synchronized Clocks

The first approach is to rely on synchronized and trustworthy clocks, and include a signed timestamp (see [I-D.birkholz-rats-tuda]) along with the Claims in the Evidence or Attestation Result. Timestamps can also be added on a per-Claim basis to distinguish the time of generation of Evidence or Attestation Result from the time that a specific Claim was generated. The clock’s trustworthiness can generally be established via Endorsements and typically requires
additional Claims about the signer's time synchronization mechanism.

In some use cases, however, a trustworthy clock might not be available. For example, in many Trusted Execution Environments (TEEs) today, a clock is only available outside the TEE and so cannot be trusted by the TEE.

10.2. Implicit Timekeeping using Nonces

A second approach places the onus of timekeeping solely on the Verifier (for Evidence) or the Relying Party (for Attestation Results), and might be suitable, for example, in case the Attester does not have a trustworthy clock or time synchronization is otherwise impaired. In this approach, a non-predictable nonce is sent by the appraising entity, and the nonce is then signed and included along with the Claims in the Evidence or Attestation Result. After checking that the sent and received nonces are the same, the appraising entity knows that the Claims were signed after the nonce was generated. This allows associating a "rough" epoch to the Evidence or Attestation Result. In this case the epoch is said to be rough because:

* The epoch applies to the entire Claim set instead of a more granular association, and

* The time between the creation of Claims and the collection of Claims is indistinguishable.

10.3. Implicit Timekeeping using Epoch IDs

A third approach relies on having epoch identifiers (or "IDs") periodically sent to both the sender and receiver of Evidence or Attestation Results by some "Epoch ID Distributor".

Epoch IDs are different from nonces as they can be used more than once and can even be used by more than one entity at the same time. Epoch IDs are different from timestamps as they do not have to convey information about a point in time, i.e., they are not necessarily monotonically increasing integers.

Like the nonce approach, this allows associating a "rough" epoch without requiring a trustworthy clock or time synchronization in order to generate or appraise the freshness of Evidence or Attestation Results. Only the Epoch ID Distributor requires access to a clock so it can periodically send new epoch IDs.
The most recent epoch ID is included in the produced Evidence or Attestation Results, and the appraising entity can compare the epoch ID in received Evidence or Attestation Results against the latest epoch ID it received from the Epoch ID Distributor to determine if it is within the current epoch. An actual solution also needs to take into account race conditions when transitioning to a new epoch, such as by using a counter signed by the Epoch ID Distributor as the epoch ID, or by including both the current and previous epoch IDs in messages and/or checks, by requiring retries in case of mismatching epoch IDs, or by buffering incoming messages that might be associated with an epoch ID that the receiver has not yet obtained.

More generally, in order to prevent an appraising entity from generating false negatives (e.g., discarding Evidence that is deemed stale even if it is not), the appraising entity should keep an "epoch window" consisting of the most recently received epoch IDs. The depth of such epoch window is directly proportional to the maximum network propagation delay between the first to receive the epoch ID and the last to receive the epoch ID, and it is inversely proportional to the epoch duration. The appraising entity shall compare the epoch ID carried in the received Evidence or Attestation Result with the epoch IDs in its epoch window to find a suitable match.

Whereas the nonce approach typically requires the appraising entity to keep state for each nonce generated, the epoch ID approach minimizes the state kept to be independent of the number of Attesters or Verifiers from which it expects to receive Evidence or Attestation Results, as long as all use the same Epoch ID Distributor.

10.4. Discussion

Implicit and explicit timekeeping can be combined into hybrid mechanisms. For example, if clocks exist and are considered trustworthy but are not synchronized, a nonce-based exchange may be used to determine the (relative) time offset between the involved peers, followed by any number of timestamp based exchanges.

It is important to note that the actual values in Claims might have been generated long before the Claims are signed. If so, it is the signer’s responsibility to ensure that the values are still correct when they are signed. For example, values generated at boot time might have been saved to secure storage until network connectivity is established to the remote Verifier and a nonce is obtained.

A more detailed discussion with examples appears in Section 16.

For a discussion on the security of epoch IDs see Section 12.3.
11. Privacy Considerations

The conveyance of Evidence and the resulting Attestation Results reveal a great deal of information about the internal state of a device as well as potentially any users of the device.

In many cases, the whole point of attestation procedures is to provide reliable information about the type of the device and the firmware/software that the device is running.

This information might be particularly interesting to many attackers. For example, knowing that a device is running a weak version of firmware provides a way to aim attacks better.

In some circumstances, if an attacker can become aware of Endorsements, Reference Values, or appraisal policies, it could potentially provide an attacker with insight into defensive mitigations. It is recommended that attention be paid to confidentiality of such information.

Additionally, many Claims in Evidence, many Claims in Attestation Results, and appraisal policies potentially contain Personally Identifying Information (PII) depending on the end-to-end use case of the remote attestation procedure. Remote attestation that includes containers and applications, e.g., a blood pressure monitor, may further reveal details about specific systems or users.

In some cases, an attacker may be able to make inferences about the contents of Evidence from the resulting effects or timing of the processing. For example, an attacker might be able to infer the value of specific Claims if it knew that only certain values were accepted by the Relying Party.

Conceptual messages (see Section 8) carrying sensitive or confidential information are expected to be integrity protected (i.e., either via signing or a secure channel) and optionally might be confidentiality protected via encryption. If there isn’t confidentiality protection of conceptual messages themselves, the underlying conveyance protocol should provide these protections.

As Evidence might contain sensitive or confidential information, Attesters are responsible for only sending such Evidence to trusted Verifiers. Some Attesters might want a stronger level of assurance of the trustworthiness of a Verifier before sending Evidence to it. In such cases, an Attester can first act as a Relying Party and ask for the Verifier’s own Attestation Result, and appraising it just as a Relying Party would appraise an Attestation Result for any other purpose.
Another approach to deal with Evidence is to remove PII from the Evidence while still being able to verify that the Attester is one of a large set. This approach is often called "Direct Anonymous Attestation". See [CCC-DeepDive] section 6.2 and [I-D.ietf-rats-daa] for more discussion.

12. Security Considerations

This document provides an architecture for doing remote attestation. No specific wire protocol is documented here. Without a specific proposal to compare against, it is impossible to know if the security threats listed below have been mitigated well.

The security considerations below should be read as being essentially requirements against realizations of the RATS Architecture. Some threats apply to protocols, some are against implementations (code), and some threats are against physical infrastructure (such as factories).

The fundamental purpose of the RATS architecture is to allow a Relying Party to establish a basis for trusting the Attester.

12.1. Attester and Attestation Key Protection

Implementers need to pay close attention to the protection of the Attester and the manufacturing processes for provisioning attestation key material. If either of these are compromised, intended levels of assurance for RATS are compromised because attackers can forge Evidence or manipulate the Attesting Environment. For example, a Target Environment should not be able to tamper with the Attesting Environment that measures it, by isolating the two environments from each other in some way.

Remote attestation applies to use cases with a range of security requirements, so the protections discussed here range from low to high security where low security may be limited to application or process isolation by the device's operating system, and high security may involve specialized hardware to defend against physical attacks on a chip.

12.1.1. On-Device Attester and Key Protection

It is assumed that an Attesting Environment is sufficiently isolated from the Target Environment it collects Claims about and that it signs the resulting Claims set with an attestation key, so that the Target Environment cannot forge Evidence about itself. Such an isolated environment might be provided by a process, a dedicated chip, a TEE, a virtual machine, or another secure mode of operation.
The Attesting Environment must be protected from unauthorized modification to ensure it behaves correctly. Confidentiality protection of the Attesting Environment’s signing key is vital so it cannot be misused to forge Evidence.

In many cases the user or owner of a device that includes the role of Attester must not be able to modify or extract keys from the Attesting Environments, to prevent creating forged Evidence. Some common examples include the user of a mobile phone or FIDO authenticator.

Measures for a minimally protected system might include process or application isolation provided by a high-level operating system, and restricted access to root or system privileges. In contrast, for really simple single-use devices that don’t use a protected mode operating system, like a Bluetooth speaker, the only factual isolation might be the sturdy housing of the device.

Measures for a moderately protected system could include a special restricted operating environment, such as a TEE. In this case, only security-oriented software has access to the Attester and key material.

Measures for a highly protected system could include specialized hardware that is used to provide protection against chip decapping attacks, power supply and clock glitching, faulting injection and RF and power side channel attacks.

12.1.2. Attestation Key Provisioning Processes

Attestation key provisioning is the process that occurs in the factory or elsewhere to establish signing key material on the device and the validation key material off the device. Sometimes this procedure is referred to as personalization or customization.

The keys generated in the factory, whether generated in the device or off-device by the factory SHOULD be generated by a Cryptographically Strong Sequence ([RFC4086], Section 6.2).

12.1.2.1. Off-Device Key Generation

One way to provision key material is to first generate it external to the device and then copy the key onto the device. In this case, confidentiality protection of the generator, as well as for the path over which the key is provisioned, is necessary. The manufacturer needs to take care to protect corresponding key material with measures appropriate for its value.
The degree of protection afforded to this key material can vary by the intended function of the device and the specific practices of the device manufacturer or integrator. The confidentiality protection is fundamentally based upon some amount of physical protection: while encryption is often used to provide confidentiality when a key is conveyed across a factory, where the attestation key is created or applied, it must be available in an unencrypted form. The physical protection can therefore vary from situations where the key is unencrypted only within carefully controlled secure enclaves within silicon, to situations where an entire facility is considered secure, by the simple means of locked doors and limited access.

The cryptography that is used to enable confidentiality protection of the attestation key comes with its own requirements to be secured. This results in recursive problems, as the key material used to provision attestation keys must again somehow have been provisioned securely beforehand (requiring an additional level of protection, and so on).

So, this is why, in general, a combination of some physical security measures and some cryptographic measures is used to establish confidentiality protection.

12.1.2.2. On-Device Key Generation

When key material is generated within a device and the secret part of it never leaves the device, then the problem may lessen. For public-key cryptography, it is, by definition, not necessary to maintain confidentiality of the public key; however integrity of the chain of custody of the public key is necessary in order to avoid attacks where an attacker is able get a key they control endorsed.

To summarize: attestation key provisioning must ensure that only valid attestation key material is established in Attesters.

12.2. Integrity Protection

Any solution that conveys information in any conceptual message (see Section 8) must support end-to-end integrity protection and replay attack prevention, and often also needs to support additional security properties, including:

* end-to-end encryption,

* denial of service protection,

* authentication,
* auditing,
* fine grained access controls, and
* logging.

Section 10 discusses ways in which freshness can be used in this architecture to protect against replay attacks.

To assess the security provided by a particular appraisal policy, it is important to understand the strength of the root of trust, e.g., whether it is mutable software, or firmware that is read-only after boot, or immutable hardware/ROM.

It is also important that the appraisal policy was itself obtained securely. If an attacker can configure or modify appraisal policies, Endorsements or Reference Values for a Relying Party or for a Verifier, then integrity of the process is compromised.

Security protections in RATS may be applied at different layers, whether by a conveyance protocol, or an information encoding format. This architecture expects conceptual messages to be end-to-end protected based on the role interaction context. For example, if an Attester produces Evidence that is relayed through some other entity that doesn’t implement the Attester or the intended Verifier roles, then the relaying entity should not expect to have access to the Evidence.

12.3. Epoch ID-based Attestation

Epoch IDs, described in Section 10.3, can be tampered with, replayed, dropped, delayed, and reordered by an attacker.

An attacker could be either external or belong to the distribution group, for example, if one of the Attester entities have been compromised.

An attacker who is able to tamper with epoch IDs can potentially lock all the participants in a certain epoch of choice for ever, effectively freezing time. This is problematic since it destroys the ability to ascertain freshness of Evidence and Attestation Results.

To mitigate this threat, the transport should be at least integrity protected and provide origin authentication.
Selective dropping of epoch IDs is equivalent to pinning the victim node to a past epoch. An attacker could drop epoch IDs to only some entities and not others, which will typically result in a denial of service due to the permanent staleness of the Attestation Result or Evidence.

Delaying or reordering epoch IDs is equivalent to manipulating the victim’s timeline at will. This ability could be used by a malicious actor (e.g., a compromised router) to mount a confusion attack where, for example, a Verifier is tricked into accepting Evidence coming from a past epoch as fresh, while in the meantime the Attester has been compromised.

Reordering and dropping attacks are mitigated if the transport provides the ability to detect reordering and drop. However, the delay attack described above can’t be thwarted in this manner.

12.4. Trust Anchor Protection

As noted in Section 7, Verifiers and Relying Parties have trust anchor stores that must be secured. [RFC6024] contains more discussion of trust anchor store requirements for protecting public keys. Section 6 of [NIST-800-57-pl] contains a comprehensive treatment of the topic, including the protection of symmetric key material. Specifically, a trust anchor store must resist modification against unauthorized insertion, deletion, and modification. Additionally, if the trust anchor is a symmetric key, the trust anchor store must not allow unauthorized read.

If certificates are used as trust anchors, Verifiers and Relying Parties are also responsible for validating the entire certificate path up to the trust anchor, which includes checking for certificate revocation. See Section 6 of [RFC5280] for details.

13. IANA Considerations

This document does not require any actions by IANA.

14. Acknowledgments

Special thanks go to Joerg Borchert, Nancy Cam-Winget, Jessica Fitzgerald-McKay, Diego Lopez, Laurence Lundblade, Paul Rowe, Hannes Tschofenig, Frank Xia, and David Wooten.
15. Notable Contributions

Thomas Hardjono created initial versions of the terminology section in collaboration with Ned Smith. Eric Voit provided the conceptual separation between Attestation Provision Flows and Attestation Evidence Flows. Monty Wisemen created the content structure of the first three architecture drafts. Carsten Bormann provided many of the motivational building blocks with respect to the Internet Threat Model.

16. Appendix A: Time Considerations

Section 10 discussed various issues and requirements around freshness of evidence, and summarized three approaches that might be used by different solutions to address them. This appendix provides more details with examples to help illustrate potential approaches, to inform those creating specific solutions.

The table below defines a number of relevant events, with an ID that is used in subsequent diagrams. The times of said events might be defined in terms of an absolute clock time, such as the Coordinated Universal Time timescale, or might be defined relative to some other timestamp or timeticks counter, such as a clock resetting its epoch each time it is powered on.

Table 1

Using the table above, a number of hypothetical examples of how a solution might be built are illustrated below. This list is not intended to be complete, but is just representative enough to highlight various timing considerations.

All times are relative to the local clocks, indicated by an "_a" (Attester), "_v" (Verifier), or "_r" (Relying Party) suffix.

Times with an appended Prime (’) indicate a second instance of the same event.

How and if clocks are synchronized depends upon the model.

In the figures below, curly braces indicate containment. For example, the notation Evidence{foo} indicates that ‘foo’ is contained in the Evidence and is thus covered by its signature.
16.1. Example 1: Timestamp-based Passport Model Example

The following example illustrates a hypothetical Passport Model solution that uses timestamps and requires roughly synchronized clocks between the Attester, Verifier, and Relying Party, which depends on using a secure clock synchronization mechanism. As a result, the receiver of a conceptual message containing a timestamp can directly compare it to its own clock and timestamps.

```
<table>
<thead>
<tr>
<th>Attester</th>
<th>Verifier</th>
<th>Relying Party</th>
</tr>
</thead>
<tbody>
<tr>
<td>time(VG_a)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>time(EG_a)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Evidence(time(EG_a))</td>
<td>time(RG_v)</td>
<td></td>
</tr>
<tr>
<td>Attestation Result</td>
<td>{time(RG_v),time(RX_v)}</td>
<td></td>
</tr>
<tr>
<td>Attestation Result</td>
<td>time(RA_r)</td>
<td></td>
</tr>
<tr>
<td>time(OP_r)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

The Verifier can check whether the Evidence is fresh when appraising it at time(RG_v) by checking time(RG_v) - time(EG_a) < Threshold, where the Verifier’s threshold is large enough to account for the maximum permitted clock skew between the Verifier and the Attester.

If time(VG_a) is also included in the Evidence along with the Claim value generated at that time, and the Verifier decides that it can trust the time(VG_a) value, the Verifier can also determine whether the Claim value is recent by checking time(RG_v) - time(VG_a) < Threshold. The threshold is decided by the Appraisal Policy for Evidence, and again needs to take into account the maximum permitted clock skew between the Verifier and the Attester.

The Relying Party can check whether the Attestation Result is fresh when appraising it at time(RA_r) by checking time(RA_r) - time(RG_v) < Threshold, where the Relying Party’s threshold is large enough to account for the maximum permitted clock skew between the Relying Party and the Verifier. The result might then be used for some time (e.g., throughout the lifetime of a connection established at
time(RA_r)). The Relying Party must be careful, however, to not allow continued use beyond the period for which it deems the Attestation Result to remain fresh enough. Thus, it might allow use (at time(OP_r)) as long as time(OP_r) - time(RG_v) < Threshold. However, if the Attestation Result contains an expiry time time(RX_v) then it could explicitly check time(OP_r) < time(RX_v).

16.2. Example 2: Nonce-based Passport Model Example

The following example illustrates a hypothetical Passport Model solution that uses nonces instead of timestamps. Compared to the timestamp-based example, it requires an extra round trip to retrieve a nonce, and requires that the Verifier and Relying Party track state to remember the nonce for some period of time.

The advantage is that it does not require that any clocks are synchronized. As a result, the receiver of a conceptual message containing a timestamp cannot directly compare it to its own clock or timestamps. Thus we use a suffix ("a" for Attester, "v" for Verifier, and "r" for Relying Party) on the IDs below indicating which clock generated them, since times from different clocks cannot be compared. Only the delta between two events from the sender can be used by the receiver.

![Diagram of Nonce-based Passport Model Example]
In this example solution, the Verifier can check whether the Evidence is fresh at time(RG_v) by verifying that time(RG_v)-time(NS_v) < Threshold.

The Verifier cannot, however, simply rely on a Nonce to determine whether the value of a Claim is recent, since the Claim value might have been generated long before the nonce was sent by the Verifier. However, if the Verifier decides that the Attester can be trusted to correctly provide the delta time(EG_a)-time(VG_a), then it can determine recency by checking time(RG_v)-time(NS_v) + time(EG_a)-time(VG_a) < Threshold.

Similarly if, based on an Attestation Result from a Verifier it trusts, the Relying Party decides that the Attester can be trusted to correctly provide time deltas, then it can determine whether the Attestation Result is fresh by checking time(OP_r)-time(NS_r) + time(RR_a)-time(EG_a) < Threshold. Although the Nonce2 and time(RR_a)-time(EG_a) values cannot be inside the Attestation Result, they might be signed by the Attester such that the Attestation Result vouches for the Attester’s signing capability.

The Relying Party must still be careful, however, to not allow continued use beyond the period for which it deems the Attestation Result to remain valid. Thus, if the Attestation Result sends a validity lifetime in terms of time(RX_v)-time(RG_v), then the Relying Party can check time(OP_r)-time(NS_r) < time(RX_v)-time(RG_v).

16.3. Example 3: Epoch ID-based Passport Model Example

The example in Figure 10 illustrates a hypothetical Passport Model solution that uses epoch IDs instead of nonces or timestamps.

The Epoch ID Distributor broadcasts epoch ID I which starts a new epoch E for a protocol participant upon reception at time(IR).

The Attester generates Evidence incorporating epoch ID I and conveys it to the Verifier.

The Verifier appraises that the received epoch ID I is "fresh" according to the definition provided in Section 10.3 whereby retries are required in the case of mismatching epoch IDs, and generates an Attestation Result. The Attestation Result is conveyed to the Attester.

After the transmission of epoch ID I’ a new epoch E’ is established when I’ is received by each protocol participant. The Attester relays the Attestation Result obtained during epoch E (associated with epoch ID I) to the Relying Party using the epoch ID for the
current epoch \( I' \). If the Relying Party had not yet received \( I' \), then the Attestation Result would be rejected, but in this example, it is received.

In the illustrated scenario, the epoch ID for relaying an Attestation Result to the Relying Party is current, while a previous epoch ID was used to generate Verifier evaluated evidence. This indicates that at least one epoch transition has occurred, and the Attestation Results may only be as fresh as the previous epoch. If the Relying Party remembers the previous epoch ID \( I \) during an epoch window as discussed in Section 10.3, and the message is received during that window, the Attestation Result is accepted as fresh, and otherwise it is rejected as stale.

![Epoch ID-based Passport Model](image)

Figure 10: Epoch ID-based Passport Model

16.4. Example 4: Timestamp-based Background-Check Model Example

The following example illustrates a hypothetical Background-Check Model solution that uses timestamps and requires roughly synchronized clocks between the Attester, Verifier, and Relying Party.
16.5. Example 5: Nonce-based Background-Check Model Example

The following example illustrates a hypothetical Background-Check Model solution that uses nonces and thus does not require that any clocks are synchronized. In this example solution, a nonce is generated by a Verifier at the request of a Relying Party, when the Relying Party needs to send one to an Attester.
The Verifier can check whether the Evidence is fresh, and whether a Claim value is recent, the same as in Example 2 above.

However, unlike in Example 2, the Relying Party can use the Nonce to determine whether the Attestation Result is fresh, by verifying that \( \text{time(OR_r)} - \text{time(NR_r)} < \text{Threshold} \).

The Relying Party must still be careful, however, to not allow continued use beyond the period for which it deems the Attestation Result to remain valid. Thus, if the Attestation Result sends a validity lifetime in terms of \( \text{time(RX_v)} - \text{time(RG_v)} \), then the Relying Party can check \( \text{time(OR_r)} - \text{time(ER_r)} < \text{time(RX_v)} - \text{time(RG_v)} \).

Abstract

This document maps the concept of Direct Anonymous Attestation (DAA) to the Remote Attestation Procedures (RATS) Architecture. The role DAA Issuer is introduced and its interactions with existing RATS roles is specified.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 5 June 2022.

Please review these documents carefully, as they describe your rights and restrictions with respect to this document. Code Components
1. Introduction

Remote ATtestation procedureS (RATS, [I-D.ietf-rats-architecture]) describe interactions between well-defined architectural constituents in support of Relying Parties that require an understanding about the trustworthiness of a remote peer. The identity of an Attester and its corresponding Attesting Environments play a vital role in RATS. A common way to refer to such an identity is the Authentication Secret ID as defined in the Reference Interaction Models for RATS [I-D.ietf-rats-reference-interaction-models]. The fact that every Attesting Environment can be uniquely identified in the context of the RATS architecture is not suitable for every application of remote attestation. Additional issues may arise when Personally identifiable information (PII) -- whether obfuscated or in clear text -- are included in attestation Evidence or even corresponding Attestation Results. This document illustrates how Direct Anonymous Attestation (DAA) can mitigate the issue of uniquely (re-)identifiable Attesting Environments. To accomplish that goal, a new RATS role -- the DAA Issuer -- is introduced and its duties as well as its interactions with other RATS roles are specified.
2. Terminology

This document uses the following set of terms, roles, and concepts as defined in [I-D.ietf-rats-architecture]: Attester, Verifier, Relying Party, Conceptual Message, Evidence, Attestation Result, Attesting Environment. The role of Endorser, also defined in [I-D.ietf-rats-architecture], needs to be adapted and details are given below.

Additionally, this document uses and adapts, as necessary, the following concepts and information elements as defined in [I-D.ietf-rats-reference-interaction-models]: Attester Identity, Authentication Secret, Authentication Secret ID

A PKIX Certificate is an X.509v3 format certificate as specified by [RFC5280].

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

3. Direct Anonymous Attestation

Figure 1 shows the data flows between the different RATS roles involved in DAA.
DAA [DAA] is a signature scheme that allows the privacy of users that are associated with an Attester (e.g. its owner) to be maintained. Essentially, DAA can be seen as a group signature scheme with the feature that given a DAA signature no-one can find out who the signer is, i.e., the anonymity is not revocable. To be able to sign anonymously, an Attester has to obtain a credential from a DAA Issuer. The DAA Issuer uses a private/public key pair to generate credentials for a group of Attesters and makes the public key (in the form of a public key certificate) available to the verifier in order to enable them to validate the Evidence received.

In order to support these DAA signatures, the DAA Issuer MUST associate a single key pair with a group of Attesters and use the same key pair when creating the credentials for all of the Attesters.
in this group. The DAA Issuer’s group public key certificate replaces the individual Attester Identity documents during authenticity validation as a part of the appraisal of Evidence conducted by a verifier. This is in contrast to intuition that there has to be a unique Attester Identity per device.

For DAA, the role of the Endorser is essentially the same, but they now provide Attester endorsement documents to the DAA Issuer rather than directly to the verifier. These Attester endorsement documents enable the Attester to obtain a credential from the DAA Issuer.

4. DAA changes to the RATS Architecture

In order to enable the use of DAA, a new conceptual message, the Credential Request, is defined and a new role, the DAA Issuer role, is added to the roles defined in the RATS Architecture.

Credential Request: An Attester sends a Credential Request to the DAA Issuer to obtain a credential. This request contains information about the DAA key that the Attester will use to create evidence and together with Attester endorsement information that is provided by the Endorser to confirm that the request came from a valid Attester.

DAA Issuer: A RATS role that offers zero-knowledge proofs based on public-key certificates used for a group of Attesters (Group Public Keys) [DAA]. How this group of Attesters is defined is not specified here, but the group must be large enough for the necessary anonymity to be assured.

Effectively, these certificates share the semantics of Endorsements, with the following exceptions:

* Upon receiving a Credential Request from an Attester, the associated group private key is used by the DAA Issuer to provide the Attester with a credential that it can use to convince the Verifier that its Evidence is valid. To keep their anonymity the Attester randomizes this credential each time that it is used. Although the DAA Issuer knows the Attester Identity and can associate this with the credential issued, randomisation ensures that the Attester’s identity cannot be revealed to anyone, including the Issuer.

* The Verifier can use the DAA Issuer’s group public key certificate, together with the randomized credential from the Attester, to confirm that the Evidence comes from a valid Attester without revealing the Attester’s identity.
* A credential is conveyed from a DAA Issuer to an Attester in combination with the conveyance of the group public key certificate from DAA Issuer to Verifier.

5. Additions to Remote Attestation principles

In order to ensure an appropriate conveyance of Evidence via interaction models in general, the following prerequisite considering Attester Identity MUST be in place to support the implementation of interaction models.

Attestation Evidence Authenticity: Attestation Evidence MUST be correct and authentic.

In order to provide proofs of authenticity, Attestation Evidence SHOULD be cryptographically associated with an identity document that is a randomised DAA credential.

The following information elements define extensions for corresponding information elements defined in [I-D.ietf-rats-reference-interaction-models] and that are vital to all types of reference interaction models. Varying from solution to solution, generic information elements can be either included in the scope of protocol messages (instantiating Conceptual Messages defined by the RATS architecture) or can be included in additional protocol parameters of protocols that facilitate the conveyance of RATS Conceptual Messages. Ultimately, the following information elements are required by any kind of scalable remote attestation procedure using DAA with one of RATS’s reference interaction models.

Attester Identity ('attesterIdentity'): _mandatory_

In DAA, the Attester’s identity is not revealed to the verifier. The Attester is issued with a credential by the DAA Issuer that is randomised and then used to anonymously confirm the validity of their evidence. The evidence is verified using the DAA Issuer’s group public key.

Authentication Secret IDs ('authSecID'): _mandatory_

In DAA, Authentication Secret IDs are represented by the DAA Issuer’s group public key that MUST be used to create DAA credentials for the corresponding Authentication Secrets used to protect Evidence.

In DAA, an Authentication Secret ID does not identify a unique
Attesting Environment but is associated with a group of Attesting Environments. This is because an Attesting Environment should not be distinguishable and the DAA credential which represents the Attesting Environment is randomised each time it used.

6. Privacy Considerations

As outlined about for DAA to provide privacy for the Attester the DAA group must be large enough to stop the Verifier identifying the Attester.

Randomization of the DAA credential by the Attester means that collusion between the DAA Issuer and Verifier, will not give them any advantage when trying to identify the Attester.

For DAA, the Attestation Evidence conveyed to the Verifier MUST not uniquely identify the Attester. If the Attestation Evidence is unique to an Attester other cryptographic techniques can be used, for example, property based attestation. (Henk -- reference follows)

7. Security Considerations

The anonymity property of DAA makes revocation difficult. Well known solutions include: 1. Rogue attester revocation -- if the an Attester’s private key is compromised and known by the Verifier then any DAA signature from that Attester can be revoked. 2. EPID - Intel’s Enhanced Privacy ID -- this requires the Attester to prove (as part of their Attestation) that their credential was not used to generate any signature in a signature revocation list.

There are no other special security considerations for DAA over and above those specified in the RATS architecture document [I-D.ietf-rats-architecture].

8. Implementation Considerations

The new DAA Issuer role can be implemented in a number of ways, for example: 1. As a stand-alone service like a Certificate Authority, a Privacy CA. 2. As a part of the Attester’s manufacture. The Endorser and the DAA Issuer could be the same entity and the manufacturer would then provide a certificate for the group public key to the Verifier.
9. IANA Considerations

We don’t yet.

The Entity Attestation Token (EAT)
draft-ietf-rats-eat-13

Abstract

An Entity Attestation Token (EAT) provides an attested claims set that describes state and characteristics of an entity, a device like a phone, IoT device, network equipment or such. This claims set is used by a relying party, server or service to determine how much it wishes to trust the entity.

An EAT is either a CBOR Web Token (CWT) or JSON Web Token (JWT) with attestation-oriented claims. To a large degree, all this document does is extend CWT and JWT.

1. Introduction

EAT provides the definition of a base set of claims that can be made about an entity, a device, some software and/or some hardware. This claims set is received by a relying party who uses it to decide if and how it will interact with the remote entity. It may choose to not trust the entity and not interact with it. It may choose to trust it. It may partially trust it, for example allowing monetary transactions only up to a limit.

EAT defines the encoding of the claims set in CBOR [RFC8949] and JSON [RFC7159]. EAT is an extension to CBOR Web Token (CWT) [RFC8392] and JSON Web Token (JWT) [RFC7519].

The claims set is secured in transit with the same mechanisms used by CWT and JWT, in particular CBOR Object Signing and Encryption (COSE) [RFC8152] and JSON Object Signing and Encryption (JOSE) [RFC7516]. Authenticity and integrity protection must always be provided. Privacy (encryption) may additionally be provided. The key material used to sign and encrypt is specifically created and provisioned for the purpose of attestation. It is the use of this key material that make the claims set "attested" rather than just some parameters sent to the relying party by the device.
EAT is focused on authenticating, identifying and characterizing implementations where implementations are devices, chips, hardware, software and such. This is distinct from protocols like TLS [RFC8446] that authenticate and identify servers and services. It is equally distinct from protocols like SASL [RFC4422] that authenticate and identify persons.

The notion of attestation is large, ranging over a broad variety of use cases and security levels. Here are a few examples of claims:

- Make and model of manufactured consumer device
- Make and model of a chip or processor, particularly for a security-oriented chip
- Identification and measurement of the software running on a device
- Configuration and state of a device
- Environmental characteristics of a device like its GPS location
- Formal certifications received

EAT also supports nesting of sets of claims and EAT tokens for use with complex composite devices.

This document uses the terminology and main operational model defined in [RATS.Architecture]. In particular, it can be used for RATS Attestation Evidence and Attestation Results.

1.1. Entity Overview

The document uses the term "entity" to refer to the target of the attestation token. The claims defined in this document are claims about an entity.

An entity is an implementation in hardware, software or both.

An entity is the same as the Attester Target Environment defined in RATS Architecture.

An entity also corresponds to a "system component" as defined in the Internet Security Glossary [RFC4949]. That glossary also defines "entity" and "system entity" as something that may be a person or organization as well as a system component. Here "entity" never refers to a person or organization.

An entity is never a server or a service.
An entity may be the whole device or it may be a subsystem, a subsystem of a subsystem and so on. EAT allows claims to be organized into submodules, nested EATs and so on. See Section 4.2.19. The entity to which a claim applies is the submodule in which it appears, or to the top-level entity if it doesn’t appear in a submodule.

Some examples of entities:

- A Secure Element
- A TEE
- A card in a network router
- A network router, perhaps with each card in the router a submodule
- An IoT device
- An individual process
- An app on a smartphone
- A smartphone with many submodules for its many subsystems
- A subsystem in a smartphone like the modem or the camera

An entity may have strong security like defenses against hardware invasive attacks. It may also have low security, having no special security defenses. There is no minimum security requirement to be an entity.

1.2. CWT, JWT and DEB

An EAT is primarily a claims set about an entity based on one of the following:

- CBOR Web Token (CWT) [RFC8392]
- JSON Web Token (JWT) [RFC7519]

All definitions, requirements, creation and validation procedures, security considerations, IANA registrations and so on from these carry over to EAT.

This specification extends those specifications by defining additional claims for attestation. This specification also describes the notion of a "profile" that can narrow the definition of an EAT,
ensure interoperability and fill in details for specific usage scenarios. This specification also adds some considerations for registration of future EAT-related claims.

The identification of a protocol element as an EAT, whether CBOR or JSON encoded, follows the general conventions used by CWT, JWT. Largely this depends on the protocol carrying the EAT. In some cases it may be by content type (e.g., MIME type). In other cases it may be through use of CBOR tags. There is no fixed mechanism across all use cases.

This specification adds one more top-level token type:

- Detached EAT Bundle (DEB), Section 5

A DEB is structure to hold a collection of detached claims sets and the EAT that separately provides integrity and authenticity protection for them. It can be either CBOR or JSON encoded.

Last, the definition of other token types is allowed. Of particular use may be a token type that provides no authenticity or integrity protection at all for use with transports like TLS that do provide that.

1.3. CDDL, CBOR and JSON

This document defines Concise Binary Object Representation (CBOR) [RFC8949] and Javascript Object Notation (JSON) [RFC7159] encoding for an EAT. All claims in an EAT MUST use the same encoding except where explicitly allowed. It is explicitly allowed for a nested token to be of a different encoding. Some claims explicitly contain objects and messages that may use a different encoding than the enclosing EAT.

This specification uses Concise Data Definition Language (CDDL) [RFC8610] for all definitions. The implementor interprets the CDDL to come to either the CBOR or JSON encoding. In the case of JSON, Appendix E of [RFC8610] is followed. Additional rules are given in Section 8.2.2 where Appendix E is insufficient.

In most cases where the CDDL for CBOR is different than JSON a CDDL Generic named "JC<>" is used. It is described in Appendix D.

The CWT and JWT specifications were authored before CDDL was available and did not use CDDL. This specification includes a CDDL definition of most of what is defined in [RFC8392]. Similarly, this specification includes CDDL for most of what is defined in [RFC7519]. These definitions are in Appendix D and are not normative.
1.4. Operating Model and RATS Architecture

While it is not required that EAT be used with the RATS operational model described in Figure 1 in [RATS.Architecture], or even that it be used for attestation, this document is oriented around that model.

To summarize, an Attester generates Attestation Evidence. Attestation Evidence is a claims set describing various characteristics of an entity. Attestation Evidence also is usually signed by a key that proves the entity and the evidence it produces are authentic. The claims set includes a nonce or some other means to provide freshness. EAT is designed to carry Attestation Evidence. The Attestation Evidence goes to a Verifier where the signature is verified. Some of the claims may also be checked against Reference Values. The Verifier then produces Attestation Results which is also usually a claims set. EAT is also designed to carry Attestation Results. The Attestation Results go to the Relying Party which is the ultimate consumer of the Remote Attestation Procedure. The Relying Party uses the Attestation Results as needed for the use case, perhaps allowing an entity on the network, allowing a financial transaction or such.

Note that sometimes the Verifier and Relying Party are not separate and thus there is no need for a protocol to carry Attestation Results.

1.4.1. Relationship between Attestation Evidence and Attestation Results

Any claim defined in this document or in the IANA CWT or JWT registry may be used in Attestation Evidence or Attestation Results.

The relationship of claims in Attestation Results to Attestation Evidence is fundamentally governed by the Verifier and the Verifier’s Policy.

A common use case is for the Verifier and its Policy to perform checks, calculations and processing with Attestation Evidence as the input to produce a summary result in Attestation Results that indicates the overall health and status of the entity. For example, measurements in Attestation Evidence may be compared to Reference Values the results of which are represented as a simple pass/fail in Attestation Results.

It is also possible that some claims in the Attestation Evidence will be forwarded unmodified to the Relying Party in Attestation Results. This forwarding is subject to the Verifier’s implementation and
Policy. The Relying Party should be aware of the Verifier's Policy to know what checks it has performed on claims it forwards.

The Verifier may also modify or transform claims it forwards. This may be to implement some privacy preservation functionality.

It is also possible the Verifier will put claims in the Attestation Results that give details about the entity that it has computed or looked up in a database. For example, the Verifier may be able to put a HW OEM ID Claim in the Attestation Results by performing a look up based on a UEID (serial number) it received in Attestation Evidence.

There are no fixed rules for how a Verifier processes Attestation Evidence to produce Attestation Results. What is important is the Relying Party understand what the Verifier does and what its policies are.

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

This document reuses terminology from JWT [RFC7519] and CWT [RFC8392].

Claim: A piece of information asserted about a subject. A claim is represented as pair with a value and either a name or key to identify it.

Claim Name: A unique text string that identifies the claim. It is used as the claim name for JSON encoding.

Claim Key: The CBOR map key used to identify a claim.

Claim Value: The value portion of the claim. A claim value can be any CBOR data item or JSON value.

CWT/JWT Claims Set: The CBOR map or JSON object that contains the claims conveyed by the CWT or JWT.

This document reuses terminology from RATS Architecture [RATS.Architecture]
Attester: A role performed by an entity (typically a device) whose Evidence must be appraised in order to infer the extent to which the Attester is considered trustworthy, such as when deciding whether it is authorized to perform some operation.

Verifier: A role that appraises the validity of Attestation Evidence about an Attester and produces Attestation Results to be used by a Relying Party.

Relying Party: A role that depends on the validity of information about an Attester, for purposes of reliably applying application specific actions. Compare /relying party/ in [RFC4949].

Attestation Evidence: A Claims Set generated by an Attester to be appraised by a Verifier. Attestation Evidence may include configuration data, measurements, telemetry, or inferences.

Attestation Results: The output generated by a Verifier, typically including information about an Attester, where the Verifier vouches for the validity of the results.

Reference Values: A set of values against which values of Claims can be compared as part of applying an Appraisal Policy for Attestation Evidence. Reference Values are sometimes referred to in other documents as known-good values, golden measurements, or nominal values, although those terms typically assume comparison for equality, whereas here Reference Values might be more general and be used in any sort of comparison.

3. Top-Level Token Definition

An EAT is a "message", a "token", or such whose content is a Claims-Set about an entity or some number of entities. An EAT MUST always contain a Claims-Set.

An EAT may be encoded in CBOR or JSON as defined here. While not encouraged, other documents may define EAT encoding in other formats.

EAT as defined here is always integrity and authenticity protected through use of CWT or JWT. Other token formats using other methods of protection may be defined outside this document.

This document also defines the Detached EAT Bundle Section 5, a bundle of some detached Claims-Sets and CWTs or JWTs that provide protection for the detached Claims-Set.
The following CDDL defines the top-levels of an EAT token as a socket indicating future token formats may be defined. See Appendix D for the CDDL definitions of a CWT and JWT.

Nesting of EATs is allowed and defined in Section 4.2.19.1.2. This nesting includes nesting of a token that is a different format than the enclosing token. The definition of Nested-Token references the CDDL defined in this section. When new token formats are defined, the means for identification in a nested token MUST also be defined.

EAT-CBOR-Token = $$EAT-CBOR-Tagged-Token / $$EAT-CBOR-Untagged-Token

$$EAT-CBOR-Tagged-Token /= CWT-Tagged-Message
$$EAT-CBOR-Tagged-Token /= DEB-Tagged-Message

$$EAT-CBOR-Untagged-Token /= CWT-Untagged-Message
$$EAT-CBOR-Untagged-Token /= DEB-Untagged-Message

EAT-JSON-Token = $$EAT-JSON-Token-Formats

$$EAT-JSON-Token-Formats /= JWT-Message
$$EAT-JSON-Token-Formats /= DEB-Untagged-Message

4. The Claims

This section describes new claims defined for attestation that are to be added to the CWT [IANA.CWT.Claims] and JWT [IANA.JWT.Claims] IANA registries.

This section also describes how several extant CWT and JWT claims apply in EAT.

CDDL, along with a text description, is used to define each claim independent of encoding. Each claim is defined as a CDDL group. In Section 8 on encoding, the CDDL groups turn into CBOR map entries and JSON name/value pairs.

Each claim described has a unique text string and integer that identifies it. CBOR encoded tokens MUST use only the integer for Claim Keys. JSON encoded tokens MUST use only the text string for Claim Names.

4.1. Nonce Claim (nonce)

All EATs MUST have a nonce to prevent replay attacks.

This claim is either a single byte or text string or an array of byte or text strings. The array is to accommodate multistage EAT...
verification and consumption. See the extensive discussion on attestation freshness in Appendix A of RATS Architecture [RATS.Architecture].

A claim named "nonce" is previously defined and registered with IANA for JWT, but MUST not be used in an EAT. It does not support multiple nonces. No previous nonce claim was defined for CWT.

The nonce MUST have 64 bits of entropy as fewer bits are unlikely to be secure. A maximum nonce size is set to limit the memory required for an implementation. All receivers MUST be able to accommodate the maximum size.

In CBOR, the nonce is a byte string and every bit in the byte string contributes to entropy. The minimum size is 8 bytes. The maximum size is 64 bytes.

In JSON the nonce is a text string. It is assumed that the only characters represented by the lower 7 bits will be used so the text string must be one-seventh longer. The minimum size is 10 bytes. The maximum size is 74 bytes.

\[
\text{Claims-Set-Claims} //=
\text{nonce-label} \Rightarrow \text{nonce-type} / \left[ 2 \times \text{nonce-type} \right]
\]

nonce-type = JC< tstr .size (10..74), bstr .size (8..64)>

4.2. Claims Describing the Entity

The claims in this section describe the entity itself. They describe the entity whether they occur in Attestation Evidence or occur in Attestation Results. See Section 1.4.1 for discussion on how Attestation Results relate to Attestation Evidence.

4.2.1. Universal Entity ID Claim (ueid)

A UEID identifies an individual manufactured entity like a mobile phone, a water meter, a Bluetooth speaker or a networked security camera. It may identify the entire entity or a submodule. It does not identify types, models or classes of entities. It is akin to a serial number, though it does not have to be sequential.

UEIDs MUST be universally and globally unique across manufacturers and countries. UEIDs MUST also be unique across protocols and systems, as tokens are intended to be embedded in many different protocols and systems. No two products anywhere, even in completely different industries made by two different manufacturers in two
different countries should have the same UEID (if they are not global and universal in this way, then Relying Parties receiving them will have to track other characteristics of the entity to keep entities distinct between manufacturers).

There are privacy considerations for UEIDs. See Section 10.1.

The UEID is permanent. It MUST never change for a given entity.

A UEID is constructed of a single type byte followed by the bytes that are the identifier. Several types are allowed to accommodate different industries, different manufacturing processes and to have an alternative that doesn’t require paying a registration fee.

Creation of new types requires a Standards Action [RFC8126].

UEIDs are variable length. All implementations MUST be able to receive UEIDs that are 33 bytes long (1 type byte and 256 bits). No UEID longer than 33 bytes SHOULD be sent.
<table>
<thead>
<tr>
<th>Type Byte</th>
<th>Type</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x01</td>
<td>RAND</td>
<td>This is a 128, 192 or 256-bit random number generated once and stored in the entity. This may be constructed by concatenating enough identifiers to make up an equivalent number of random bits and then feeding the concatenation through a cryptographic hash function. It may also be a cryptographic quality random number generated once at the beginning of the life of the entity and stored. It MUST NOT be smaller than 128 bits. See the length analysis in Appendix B.</td>
</tr>
<tr>
<td>0x02</td>
<td>IEEE</td>
<td>This uses the IEEE company identification registry. An EUI is either an EUI-48, EUI-60 or EUI-64 and made up of an OUI, OUI-36 or a CID, different registered company identifiers, and some unique per-entity identifier. EUIs are often the same as or similar to MAC addresses. This type includes MAC-48, an obsolete name for EUI-48. (Note that while entities with multiple network interfaces may have multiple MAC addresses, there is only one UEID for an entity) [IEEE.802-2001], [OUI.Guide].</td>
</tr>
<tr>
<td>0x03</td>
<td>IMEI</td>
<td>This is a 14-digit identifier consisting of an 8-digit Type Allocation Code and a 6-digit serial number allocated by the manufacturer, which SHALL be encoded as byte string of length 14 with each byte as the digit’s value (not the ASCII encoding of the digit; the digit 3 encodes as 0x03, not 0x33). The IMEI value encoded SHALL NOT include Luhn checksum or SVN information. See [ThreeGPP.IMEI].</td>
</tr>
</tbody>
</table>

Table 1: UEID Composition Types

UEIDs are not designed for direct use by humans (e.g., printing on the case of a device), so no textual representation is defined.

The consumer of a UEID MUST treat a UEID as a completely opaque string of bytes and not make any use of its internal structure. For example, they should not use the OUI part of a type 0x02 UEID to identify the manufacturer of the entity. Instead, they should use the OEMID claim. See Section 4.2.3. The reasons for this are:

- UEIDs types may vary freely from one manufacturer to the next.
New types of UEIDs may be created. For example, a type 0x07 UEID may be created based on some other manufacturer registration scheme.

The manufacturing process for an entity is allowed to change from using one type of UEID to another. For example, a manufacturer may find they can optimize their process by switching from type 0x01 to type 0x02 or vice versa.

A Device Identifier URN is registered for UEIDs. See Section 9.3.4.

$$Claims-Set-Claims //= (ueid-label => ueid-type)
ueid-type = JC<base64-url-text .size (12..44) , bstr .size (7..33)>

4.2.2. Semi-permanent UEIDs (SUEIDs)

An SEUID is of the same format as a UEID, but it MAY change to a different value on device life-cycle events. Examples of these events are change of ownership, factory reset and on-boarding into an IoT device management system. An entity MAY have both a UEID and SUEIDs, neither, one or the other.

There MAY be multiple SUEIDs. Each one has a text string label the purpose of which is to distinguish it from others in the token. The label MAY name the purpose, application or type of the SUEID. Typically, there will be few SUEIDs so there is no need for a formal labeling mechanism like a registry. The EAT profile MAY describe how SUEIDs should be labeled. If there is only one SUEID, the claim remains a map and there still must be a label. For example, the label for the SUEID used by FIDO Onboarding Protocol could simply be "FDO".

There are privacy considerations for SUEIDs. See Section 10.1.

A Device Identifier URN is registered for SUEIDs. See Section 9.3.4.

$$Claims-Set-Claims //= (sueids-label => sueids-type)
sueids-type = {
    + tstr => ueid-type
}
4.2.3. Hardware OEM Identification (oemid)

This claim identifies the Original Equipment Manufacturer (OEM) of the hardware. Any of the three forms described below MAY be used at the convenience of the claim sender. The receiver of this claim MUST be able to handle all three forms.

4.2.3.1. Random Number Based OEMID

The random number based OEMID MUST always 16 bytes (128 bits).

The OEM MAY create their own ID by using a cryptographic-quality random number generator. They would perform this only once in the life of the company to generate the single ID for said company. They would use that same ID in every entity they make. This uniquely identifies the OEM on a statistical basis and is large enough should there be ten billion companies.

The OEM MAY also use a hash function like SHA-256 and truncate the output to 128 bits. The input to the hash should be somethings that have at least 96 bits of entropy, but preferably 128 bits of entropy. The input to the hash MAY be something whose uniqueness is managed by a central registry like a domain name.

In JSON format tokens this MUST be base64url encoded.

4.2.3.2. IEEE Based OEMID

The IEEE operates a global registry for MAC addresses and company IDs. This claim uses that database to identify OEMs. The contents of the claim may be either an IEEE MA-L, MA-M, MA-S or an IEEE CID [IEEE.RA]. An MA-L, formerly known as an OUI, is a 24-bit value used as the first half of a MAC address. MA-M similarly is a 28-bit value uses as the first part of a MAC address, and MA-S, formerly known as OUI-36, a 36-bit value. Many companies already have purchased one of these. A CID is also a 24-bit value from the same space as an MA-L, but not for use as a MAC address. IEEE has published Guidelines for Use of EUI, OUI, and CID [OUI.Guide] and provides a lookup service [OUI.Lookup].

Companies that have more than one of these IDs or MAC address blocks SHOULD select one and prefer that for all their entities.

Commonly, these are expressed in Hexadecimal Representation as described in [IEEE.802-2001]. It is also called the Canonical format. When this claim is encoded the order of bytes in the bstr are the same as the order in the Hexadecimal Representation. For
example, an MA-L like "AC-DE-48" would be encoded in 3 bytes with values 0xAC, 0xDE, 0x48.

This format is always 3 bytes in size in CBOR.

In JSON format tokens, this MUST be base64url encoded and always 4 bytes.

4.2.3.3. IANA Private Enterprise Number Based OEMID

IANA maintains a integer-based company registry called the Private Enterprise Number (PEN) [PEN].

PENs are often used to create an OID. That is not the case here. They are used only as an integer.

In CBOR this value MUST be encoded as a major type 0 integer and is typically 3 bytes. In JSON, this value MUST be encoded as a number.

```$\text{Claims-Set-Claims} //= ( 
   \text{oemid-label} => \text{oemid-pen} / \text{oemid-ieee} / \text{oemid-random} 
)
```

doemid-pen = int

doemid-ieee = JC<doemid-ieee-json, doemid-ieee-cbor>
doemid-ieee-cbor = bstr.size 3
ndoemid-ieee-json = base64-url-text.size 4

ndoemid-random = JC<doemid-random-json, doemid-random-cbor>
doemid-random-cbor = bstr.size 16
ndoemid-random-json = base64-url-text.size 24

4.2.4. Hardware Model Claim (hardware-model)

This claim differentiates hardware models, products and variants manufactured by a particular OEM, the one identified by OEM ID in Section 4.2.3.

This claim must be unique so as to differentiate the models and products for the OEM ID. This claim does not have to be globally unique, but it can be. A receiver of this claim MUST not assume it is globally unique. To globally identify a particular product, the receiver should concatenate the OEM ID and this claim.

The granularity of the model identification is for each OEM to decide. It may be very granular, perhaps including some version
information. It may be very general, perhaps only indicating top-level products.

The purpose of this claim is to identify models within protocols, not for human-readable descriptions. The format and encoding of this claim should not be human-readable to discourage use other than in protocols. If this claim is to be derived from an already-in-use human-readable identifier, it can be run through a hash function.

There is no minimum length so that an OEM with a very small number of models can use a one-byte encoding. The maximum length is 32 bytes. All receivers of this claim MUST be able to receive this maximum size.

The receiver of this claim MUST treat it as a completely opaque string of bytes, even if there is some apparent naming or structure. The OEM is free to alter the internal structure of these bytes as long as the claim continues to uniquely identify its models.

```plaintext
$\text{Claims-Set-Claims} //= ( \
\quad \text{hardware-model-label} => \text{hardware-model-type} 
) 

\text{hardware-model-type} = \frac{\text{JC<base64-url-text .size (4..44)},}{\text{bytes .size (1..32)>}}
```

4.2.5. Hardware Version Claims (hardware-version-claims)

The hardware version is a text string the format of which is set by each manufacturer. The structure and sorting order of this text string can be specified using the version-scheme item from CoSWID [CoSWID]. It is useful to know how to sort versions so the newer can be distinguished from the older.

The hardware version can also be given by a 13-digit [EAN-13]. A new CoSWID version scheme is registered with IANA by this document in Section 9.3.3. An EAN-13 is also known as an International Article Number or most commonly as a bar code.

```plaintext
$\text{Claims-Set-Claims} //= ( \
\quad \text{hardware-version-label} => \text{hardware-version-type} 
) 

\text{hardware-version-type} = [ \
\quad \text{version: tstr,} \\
\quad \quad \text{? scheme: $version-scheme} 
] 
```
4.2.6.  Software Name Claim

This is a free-form text claim for the name of the software for the entity or submodule. A CoSWID manifest or other type of manifest can be used instead if this claim is too limited to correctly characterize the SW for the entity or submodule.

```text
Claims-Set-Claims //= ( sw-name-label => tstr )
```

4.2.7.  Software Version Claim

This makes use of the CoSWID version scheme data type to give a simple version for the software. A full CoSWID manifest or other type of manifest can be instead if this is too simple.

```text
Claims-Set-Claims //= (sw-version-label => sw-version-type)

sw-version-type = [%
  version:  tstr
  ? scheme:  $version-scheme
%
```

4.2.8.  The Security Level Claim (security-level)

This claim characterizes the entity’s ability to defend against attacks aimed at capturing the signing key, forging claims and forging EATs.

The intent of this claim is only to give the recipient a rough idea of the security the entity is aiming for. This is via a simple, non-extensible set of three levels.

This takes a broad view of the range of defenses because EAT is targeted at a broad range of use cases. The least secure level involves minimal SW defenses. The most secure level involves specialized hardware to defend against hardware-based attacks.

Only through expansive certification programs like Common Criteria and FIDO certification is it possible to sharply define security levels. Sharp definition of security levels is not possible here because the IETF doesn’t define and operate certification programs. It is also not possible here because any sharp definition of security levels would be a document larger than the EAT specification. Thus, this definition takes the view that the security level definition possible here is a simple, modest, rough characterization.

1 - Unrestricted: An entity is categorized as unrestricted when it doesn’t meet the criteria for any of the higher levels. This
level does not indicate there is no protection at all, just that the entity doesn’t qualify for the higher levels.

2 - Restricted: Entities at this level MUST meet the criteria defined in Section 4 of FIDO Allowed Restricted Operating Environments [FIDO.AROE]. Examples include TEE’s and schemes using virtualization-based security. Security at this level is aimed at defending against large-scale network/remote attacks by having a reduced attack surface.

3 - Hardware: Entities at this level are indicating they have some countermeasures to defend against physical or electrical attacks against the entity. Security at this level is aimed at defending against attackers that physically capture the entity to attack it. Examples include TPMs and Secure Elements.

The security level claimed should be for the weakest point in the entity, not the strongest. For example, if attestation key is protected by hardware, but the rest of the attester is in a TEE, the claim must be for restricted.

This set of three is not extensible so this remains a broad interoperable description of security level.

In particular use cases, alternate claims may be defined that give finer grained information than this claim.

See also the DLOAs claim in Section 4.2.15, a claim that specifically provides information about certifications received.

```
$Claims-Set-Claims //=
  ( security-level-label => security-level-type )

security-level-type = unrestricted / restricted / hardware

unrestricted       = JC< "unrestricted", 1>
restricted         = JC< "restricted", 2>
hardware           = JC< "hardware", 3>
```

4.2.9. Secure Boot Claim (secure-boot)

The value of true indicates secure boot is enabled. Secure boot is considered enabled when the firmware and operating system, are under control of the manufacturer of the entity identified in the OEMID claim described in Section 4.2.3. Control by the manufacturer of the
firmware and the operating system may be by it being in ROM, being
cryptographically authenticated, a combination of the two or similar.

$$Claims-Set-Claims //= (secure-boot-label => bool)$$

4.2.10. Debug Status Claim (debug-status)

This applies to entity-wide or submodule-wide debug facilities of the
entity like JTAG and diagnostic hardware built into chips. It
applies to any software debug facilities related to root, operating
system or privileged software that allow system-wide memory
inspection, tracing or modification of non-system software like user
mode applications.

This characterization assumes that debug facilities can be enabled
and disabled in a dynamic way or be disabled in some permanent way
such that no enabling is possible. An example of dynamic enabling is
one where some authentication is required to enable debugging. An
example of permanent disabling is blowing a hardware fuse in a chip.
The specific type of the mechanism is not taken into account. For
example, it does not matter if authentication is by a global password
or by per-entity public keys.

As with all claims, the absence of the debug level claim means it is
not reported. A conservative interpretation might assume the enabled
state.

This claim is not extensible so as to provide a common interoperable
description of debug status. If a particular implementation
considers this claim to be inadequate, it can define its own
proprietary claim. It may consider including both this claim as a
coarse indication of debug status and its own proprietary claim as a
refined indication.

The higher levels of debug disabling requires that all debug
disabling of the levels below it be in effect. Since the lowest
level requires that all of the target’s debug be currently disabled,
all other levels require that too.

There is no inheritance of claims from a submodule to a superior
module or vice versa. There is no assumption, requirement or
guarantee that the target of a superior module encompasses the
targets of submodules. Thus, every submodule must explicitly
describe its own debug state. The receiver of an EAT MUST not assume
that debug is turned off in a submodule because there is a claim
indicating it is turned off in a superior module.
An entity may have multiple debug facilities. The use of plural in the description of the states refers to that, not to any aggregation or inheritance.

The architecture of some chips or devices may be such that a debug facility operates for the whole chip or device. If the EAT for such a chip includes submodules, then each submodule should independently report the status of the whole-chip or whole-device debug facility. This is the only way the receiver can know the debug status of the submodules since there is no inheritance.

4.2.10.1. Enabled

If any debug facility, even manufacturer hardware diagnostics, is currently enabled, then this level must be indicated.

4.2.10.2. Disabled

This level indicates all debug facilities are currently disabled. It may be possible to enable them in the future. It may also be that they were enabled in the past, but they are currently disabled.

4.2.10.3. Disabled Since Boot

This level indicates all debug facilities are currently disabled and have been so since the entity booted/started.

4.2.10.4. Disabled Permanently

This level indicates all non-manufacturer facilities are permanently disabled such that no end user or developer can enable them. Only the manufacturer indicated in the OEMID claim can enable them. This also indicates that all debug facilities are currently disabled and have been so since boot/start.

4.2.10.5. Disabled Fully and Permanently

This level indicates that all debug facilities for the entity are permanently disabled.
$$\textbf{Claims-Set-Claims} //= \{ \text{debug-status-label} => \text{debug-status-type} \}$$

debug-status-type = ds-enabled /
    disabled /
    disabled-since-boot /
    disabled-permanently /
    disabled-fully-and-permanently

ds-enabled = JC< "enabled", 0 >
disabled = JC< "disabled", 1 >
disabled-since-boot = JC< "disabled-since-boot", 2 >
disabled-permanently = JC< "disabled-permanently", 3 >
disabled-fully-and-permanently = JC< "disabled-fully-and-permanently", 4 >

4.2.11. The Location Claim (location)

The location claim gives the location of the entity from which the attestation originates. It is derived from the W3C Geolocation API [W3C.GeoLoc]. The latitude, longitude, altitude and accuracy must conform to [WGS84]. The altitude is in meters above the [WGS84] ellipsoid. The two accuracy values are positive numbers in meters. The heading is in degrees relative to true north. If the entity is stationary, the heading is NaN (floating-point not-a-number). The speed is the horizontal component of the entity velocity in meters per second.

The location may have been cached for a period of time before token creation. For example, it might have been minutes or hours or more since the last contact with a GPS satellite. Either the timestamp or age data item can be used to quantify the cached period. The timestamp data item is preferred as it a non-relative time.

The age data item can be used when the entity doesn’t know what time it is either because it doesn’t have a clock or it isn’t set. The entity MUST still have a "ticker" that can measure a time interval. The age is the interval between acquisition of the location data and token creation.

See location-related privacy considerations in Section 10.2.
Claims-Set-Claims

location-type = {
  latitude => number,
  longitude => number,
  ? altitude => number,
  ? accuracy => number,
  ? altitude-accuracy => number,
  ? heading => number,
  ? speed => number,
  ? timestamp => "time-int,
  ? age => uint
}

latitude          = JC< "latitude",          1 >

age               = JC< "age",               9 >

4.2.12. The Uptime Claim (uptime)

The "uptime" claim MUST contain a value that represents the number of
seconds that have elapsed since the entity or submod was last booted.

Claims-Set-Claims

4.2.13. The Boot Odometer Claim (odometer)

The "odometer" claim contains a value that represents the number of
times the entity or submod has been booted. Support for this claim
requires a persistent storage on the device.

Claims-Set-Claims

4.2.14. The Boot Seed Claim (boot-seed)

The Boot Seed claim MUST contain a random value created at system
boot time that will allow differentiation of reports from different
boot sessions.

This value is usually public. It is not a secret and MUST NOT be
used for any purpose that a secret seed is needed, such as seeding a
random number generator.
4.2.15. The DLOA (Digital Letter of Approval) Claim (dloas)

A DLOA (Digital Letter of Approval) [DLOA] is an XML document that describes a certification that an entity has received. Examples of certifications represented by a DLOA include those issued by Global Platform and those based on Common Criteria. The DLOA is unspecific to any particular certification type or those issued by any particular organization.

This claim is typically issued by a Verifier, not an Attester. When this claim is issued by a Verifier, it MUST be because the entity has received the certification in the DLOA.

This claim MAY contain more than one DLOA. If multiple DLOAs are present, it MUST be because the entity received all of the certifications.

DLOA XML documents are always fetched from a registrar that stores them. This claim contains several data items used to construct a URL for fetching the DLOA from the particular registrar.

This claim MUST be encoded as an array with either two or three elements. The first element MUST be the URI for the registrar. The second element MUST be a platform label indicating which platform was certified. If the DLOA applies to an application, then the third element is added which MUST be an application label. The method of constructing the registrar URI, platform label and possibly application label is specified in [DLOA].

$$Claims-Set-Claims //= (boot-seed-label => binary-data)

\[
\text{dloas-label => } [ + \text{dloa-type } ]
\]

\[
dloa-type = [
    \text{dloa_registrar: general-uri}
    \text{dloa_platform_label: text}
    \text{? dloa_application_label: text}
]
\]

4.2.16. The Software Manifests Claim (manifests)

This claim contains descriptions of software present on the entity. These manifests are installed on the entity when the software is installed or are created as part of the installation process. Installation is anything that adds software to the entity, possibly factory installation, the user installing elective applications and
so on. The defining characteristic is they are created by the software manufacturer. The purpose of these claims in an EAT is to relay them without modification to the Verifier and possibly to the Relying Party.

Some manifests may be signed by their software manufacturer before they are put into this EAT claim. When such manifests are put into this claim, the manufacturer’s signature SHOULD be included. For example, the manifest might be a CoSWID signed by the software manufacturer, in which case the full signed CoSWID should be put in this claim.

This claim allows multiple formats for the manifest. For example, the manifest may be a CBOR-format CoSWID, an XML-format SWID or other. Identification of the type of manifest is always by a CoAP Content-Format integer [RFC7252]. If there is no CoAP identifier registered for the manifest format, one should be registered, perhaps in the experimental or first-come-first-served range.

This claim MUST be an array of one or more manifests. Each manifest in the claim MUST be an array of two. The first item in the array of two MUST be an integer CoAP Content-Format identifier. The second item is MUST be the actual manifest.

In CBOR-encoded EATs the manifest, whatever format it is, MUST be placed in a byte string.

In JSON-format tokens the manifest, whatever format it is, MUST be placed in a text string. When a non-text format manifest like a CBOR-encoded CoSWID is put in a JSON-encoded token, the manifest MUST be base-64 encoded.

This claim allows for multiple manifests in one token since multiple software packages are likely to be present. The multiple manifests MAY be of different formats. In some cases EAT submodules may be used instead of the array structure in this claim for multiple manifests.

When the [CoSWID] format is used, it MUST be a payload CoSWID, not an evidence CoSWID.
Claims-Set-Claims = (manifests-label => manifests-type)

manifests-type = [+ manifest-format]

manifest-format = [content-type: uint,

$\text{manifest-body-json} /= \text{base64-url-text}

suit-directive-process-dependency = 19

4.2.17. The Software Evidence Claim (swevidence)

This claim contains descriptions, lists, evidence or measurements of
the software that exists on the entity. The defining characteristic
of this claim is that its contents are created by processes on the
entity that inventory, measure or otherwise characterize the software
on the entity. The contents of this claim do not originate from the
software manufacturer.

This claim can be a [CoSWID]. When the CoSWID format is used, it
MUST be evidence CoSWIDs, not payload CoSWIDs.

Formats other than CoSWID can be used. The identification of format
is by CoAP Content Format, the same as the manifests claim in
Section 4.2.16.
$$Claims-Set-Claims /= (  
  swevidence-label => swevidence-type 
) 

swevidence-type = [+ swevidence-format] 

swevidence-format = [  
  content-type:   uint, 
  content-format: JC< $$swevidence-body-json, 
                         $$swevidence-body-cbor > 
] 

$$swevidence-body-cbor /= bytes .cbor untagged-coswid 
$$swevidence-body-json /= base64-url-text 

4.2.18. The Measurement Results Claim (measurement-results) 

This claim is a general-purpose structure for reporting comparison of measurements to expected Reference Values. This claim provides a simple standard way to report the result of a comparison as success, failure, fail to run, ... 

It is the nature of measurement systems that they are specific to the operating system, software and hardware of the entity that is being measured. It is not possible to standardize what is measured and how it is measured across platforms, OS’s, software and hardware. The recipient must obtain the information about what was measured and what it indicates for the characterization of the security of the entity from the provider of the measurement system. What this claim provides is a standard way to report basic success or failure of the measurement. In some use cases it is valuable to know if measurements succeeded or failed in a general way even if the details of what was measured is not characterized. 

This claim MAY be generated by the Verifier and sent to the Relying Party. For example, it could be the results of the Verifier comparing the contents of the swevidence claim, {#swevidence}, to Reference Values. 

This claim MAY also be generated on the entity if the entity has the ability for one subsystem to measure and evaluate another subsystem. For example, a TEE might have the ability to measure the software of the rich OS and may have the Reference Values for the rich OS. 

Within an entity, attestation target or submodule, multiple results can be reported. For example, it may be desirable to report the
results for measurements of the file system, chip configuration, installed software, running software and so on.

Note that this claim is not for reporting the overall result of a Verifier. It is solely for reporting the result of comparison to reference values.

An individual measurement result is an array of two, an identifier of the measurement and an enumerated type that is the result. The range and values of the measurement identifier varies from one measurement scheme to another.

Each individual measurement result is part of a group that may contain many individual results. Each group has a text string that names it, typically the name of the measurement scheme or system.

The claim itself consists of one or more groups.

The values for the results enumerated type are as follows:

1 - comparison successful Indicates successful comparison to reference values.

2 - comparison fail The comparison was completed and did not compare correctly to the Reference Values.

3 - comparison not run The comparison was not run. This includes error conditions such as running out of memory.

4 - measurement absent The particular measurement was not available for comparison.
$$\text{Claims-Set-Claims} = (\text{measurement-results-label} => \[ + \text{measurement-results-group} \])$$

\text{measurement-results-group} = [\text{measurement-system}: \text{tstr}, \text{measurement-results}: [ + \text{individual-result} ] ]

\text{individual-result} = [\text{results-id}: \text{tstr} / \text{binary-data}, \text{result}: \text{result-type}, ]

\text{result-type} = \text{comparison-successful} / \text{comparison-fail} / \text{comparison-not-run} / \text{measurement-absent}

\text{comparison-successful} = \text{JC< "success", 1 >}
\text{comparison-fail} = \text{JC< "fail", 2 >}
\text{comparison-not-run} = \text{JC< "not-run", 3 >}
\text{measurement-absent} = \text{JC< "absent", 4 >}

4.2.19. Submodules (submods)

Some devices are complex, having many subsystems. A mobile phone is a good example. It may have several connectivity subsystems for communications (e.g., Wi-Fi and cellular). It may have subsystems for low-power audio and video playback. It may have multiple security-oriented subsystems like a TEE and a Secure Element.

The claims for a subsystem can be grouped together in a submodule or submod.

The submods are in a single map/object, one entry per submodule. There is only one submods map/object in a token. It is identified by its specific label. It is a peer to other claims, but it is not called a claim because it is a container for a claims set rather than an individual claim. This submods part of a token allows what might be called recursion. It allows claims sets inside of claims sets inside of claims sets...
4.2.19.1. Submodule Types

The following sections define the three types of submodules:

- A submodule Claims-Set
- A nested token, which can be any valid EAT token, CBOR or JSON
- The digest of a detached Claims-Set

$$\text{Claims-Set-Claims} \equiv (\text{submods-label} \Rightarrow \{ + \text{text} \Rightarrow \text{Submodule} \})$$

Submodule = Claims-Set / Nested-Token / Detached-Submodule-Digest

4.2.19.1.1. Submodule Claims-Set

This is a subordinate Claims-Set containing claims about the submodule.

The submodule Claims-Set is produced by the same Attester as the surrounding token. It is secured using the same mechanism as the enclosing token (e.g., it is signed by the same attestation key). It roughly corresponds to an Attester Target Environment, as described in the RATS architecture.

It may contain claims that are the same as its surrounding token or superior submodules. For example, the top-level of the token may have a UEID, a submod may have a different UEID and a further subordinate submodule may also have a UEID.

The encoding of a submodule Claims-Set MUST be the same as the encoding as the token it is part of.

This data type for this type of submodule is a map/object. It is identified when decoding by it’s type being a map/object.

4.2.19.1.2. Nested Token

This type of submodule is a fully formed complete token. It is typically produced by a separate Attester. It is typically used by a Composite Device as described in RATS Architecture. In being a submodule of the surrounding token, it is cryptographically bound to the surrounding token. If it was conveyed in parallel with the surrounding token, there would be no such binding and attackers could substitute a good attestation from another device for the attestation of an errant subsystem.
A nested token does not need to use the same encoding as the enclosing token. This is to allow Composite Devices to be built without regards to the encoding supported by their Attesters. Thus, a CBOR-encoded token like a CWT can have a JWT as a nested token submodule and vice versa.

4.2.19.1.2.1. Surrounding EAT is CBOR-Encoded

This describes the encoding and decoding of CBOR or JSON-encoded tokens nested inside a CBOR-encoded token.

If the nested token is CBOR-encoded, then it MUST be a CBOR tag and MUST be wrapped in a byte string. The tag identifies whether the nested token is a CWT, a CBOR-encoded DEB, or some other CBOR-format token defined in the future. A nested CBOR-encoded token that is not a CBOR tag is NOT allowed.

If the nested token is JSON-encoded, then the data item MUST be a text string containing JSON. The JSON is defined in CDDL by JSON-Nested-Token in the next section.

When decoding, if a byte string is encountered, it is known to be a nested CBOR-encoded token. The byte string wrapping is removed. The type of the token is determined by the CBOR tag.

When decoding, if a text string is encountered, it is known to be a JSON-encoded token. The two-item array is decoded and tells the type of the JSON-encoded token.

Nested-Token = CBOR-Nested-Token

CBOR-Nested-Token =
  JSON-Token-Inside-CBOR-Token /
  CBOR-Token-Inside-CBOR-Token

CBOR-Token-Inside-CBOR-Token = bstr $EAT-CBOR-Tagged-Token

JSON-Token-Inside-CBOR-Token = tstr

4.2.19.1.2.2. Surrounding EAT is JSON-Encoded

This describes the encoding and decoding of CBOR or JSON-encoded tokens nested inside a JSON-encoded token.

The nested token MUST be an array of two, a text string type indicator and the actual token.
The string identifying the JSON-encoded token MUST be one of the following:

"JWT": The second array item MUST be a JWT formatted according to [RFC7519]

"CBOR": The second array item must be some base64url-encoded CBOR that is a tag, typically a CWT or CBOR-encoded DEB

"DEB": The second array item MUST be a JSON-encoded Detached EAT Bundle as defined in this document.

Additional types may be defined by a standards action.

When decoding, the array of two is decoded. The first item indicates the type and encoding of the nested token. If the type string is not "CBOR", then the token is JSON-encoded and of the type indicated by the string.

If the type string is "CBOR", then the token is CBOR-encoded. The base64url encoding is removed. The CBOR-encoded data is then decoded. The type of nested token is determined by the CBOR-tag. It is an error if the CBOR is not a tag.

Nested-Token = JSON-Nested-Token

JSON-Nested-Token = [
  type : "JWT" / "CBOR" / "DEB",
]

CBOR-Token-Inside-JSON-Token = base64-url-text

4.2.19.1.3. Detached Submodule Digest

This is type of submodule equivalent to a Claims-Set submodule, except the Claims-Set is conveyed separately outside of the token.

This type of submodule consists of a digest made using a cryptographic hash of a Claims-Set. The Claims-Set is not included in the token. It is conveyed to the Verifier outside of the token. The submodule containing the digest is called a detached digest. The separately conveyed Claims-Set is called a detached claims set.

The input to the digest is exactly the byte-string wrapped encoded form of the Claims-Set for the submodule. That Claims-Set can
include other submodules including nested tokens and detached digests.

The primary use for this is to facilitate the implementation of a small and secure attester, perhaps purely in hardware. This small, secure attester implements COSE signing and only a few claims, perhaps just UEID and hardware identification. It has inputs for digests of submodules, perhaps 32-byte hardware registers. Software running on the device constructs larger claim sets, perhaps very large, encodes them and digests them. The digests are written into the small secure attesters registers. The EAT produced by the small secure attester only contains the UEID, hardware identification and digests and is thus simple enough to be implemented in hardware. Probably, every data item in it is of fixed length.

The integrity protection for the larger Claims Sets will not be as secure as those originating in hardware block, but the key material and hardware-based claims will be. It is possible for the hardware to enforce hardware access control (memory protection) on the digest registers so that some of the larger claims can be more secure. For example, one register may be writable only by the TEE, so the detached claims from the TEE will have TEE-level security.

The data type for this type of submodule MUST be an array. It contains two data items, an algorithm identifier and a byte string containing the digest.

When decoding a CBOR format token the detached digest type is distinguished from the other types by it being an array. In CBOR the none of other submodule types are arrays.

When decoding a JSON format token, a little more work is required because both the nested token and detached digest types are an array. To distinguish the nested token from the detached digest, the first element in the array is examined. If it is "JWT" or "DEB", then the submodule is a nested token. Otherwise it will contain an algorithm identifier and is a detached digest.

A DEB, described in Section 5, may be used to convey detached claims sets and the token with their detached digests. EAT, however, doesn’t require use of a DEB. Any other protocols may be used to convey detached claims sets and the token with their detached digests. Note that since detached Claims-Sets are signed, protocols conveying them must make sure they are not modified in transit.
Detached-Submodule-Digest = [
    algorithm : JC< text, int >
    digest    : binary-data
]

4.2.19.2. No Inheritance

The subordinate modules do not inherit anything from the containing token. The subordinate modules must explicitly include all of their claims. This is the case even for claims like the nonce.

This rule is in place for simplicity. It avoids complex inheritance rules that might vary from one type of claim to another.

4.2.19.3. Security Levels

The security level of the non-token subordinate modules should always be less than or equal to that of the containing modules in the case of non-token submodules. It makes no sense for a module of lesser security to be signing claims of a module of higher security. An example of this is a TEE signing claims made by the non-TEE parts (e.g. the high-level OS) of the device.

The opposite may be true for the nested tokens. They usually have their own more secure key material. An example of this is an embedded secure element.

4.2.19.4. Submodule Names

The label or name for each submodule in the submods map is a text string naming the submodule. No submodules may have the same name.

4.3. Claims Describing the Token

The claims in this section provide meta data about the token they occur in. They do not describe the entity.

They may appear in Attestation Evidence or Attestation Results. When these claims appear in Attestation Evidence, they SHOULD not be passed through the Verifier into Attestation Results.

4.3.1. Token ID Claim (cti and jti)

CWT defines the "cti" claim. JWT defines the "jti" claim. These are equivalent to each other in EAT and carry a unique token identifier as they do in JWT and CWT. They may be used to defend against re use of the token but are distinct from the nonce that is used by the Relying Party to guarantee freshness and defend against replay.
4.3.2. Timestamp claim (iat)

The "iat" claim defined in CWT and JWT is used to indicate the date-of-creation of the token, the time at which the claims are collected and the token is composed and signed.

The data for some claims may be held or cached for some period of time before the token is created. This period may be long, even days. Examples are measurements taken at boot or a geographic position fix taken the last time a satellite signal was received. There are individual timestamps associated with these claims to indicate their age is older than the "iat" timestamp.

CWT allows the use floating-point for this claim. EAT disallows the use of floating-point. An EAT token MUST NOT contain an iat claim in float-point format. Any recipient of a token with a floating-point format iat claim MUST consider it an error. A 64-bit integer representation of epoch time can represent a range of +/- 500 billion years, so the only point of a floating-point timestamp is to have precession greater than one second. This is not needed for EAT.

4.3.3. The Profile Claim (profile)

See Section 7 for the detailed description of a profile.

A profile is identified by either a URL or an OID. Typically, the URI will reference a document describing the profile. An OID is just a unique identifier for the profile. It may exist anywhere in the OID tree. There is no requirement that the named document be publicly accessible. The primary purpose of the profile claim is to uniquely identify the profile even if it is a private profile.

The OID is always absolute and never relative.

See Section 8.2.1 for OID and URI encoding.

Note that this is named "eat_profile" for JWT and is distinct from the already registered "profile" claim in the JWT claims registry.

4.3.4. The Intended Use Claim (intended-use)

EAT’s may be used in the context of several different applications. The intended-use claim provides an indication to an EAT consumer about the intended usage of the token. This claim can be used as a way for an application using EAT to internally distinguish between different ways it uses EAT.
1 - Generic: Generic attestation describes an application where the EAT consumer requires the most up-to-date security assessment of the attesting entity. It is expected that this is the most commonly-used application of EAT.

2- Registration: Entities that are registering for a new service may be expected to provide an attestation as part of the registration process. This intended-use setting indicates that the attestation is not intended for any use but registration.

3 - Provisioning: Entities may be provisioned with different values or settings by an EAT consumer. Examples include key material or device management trees. The consumer may require an EAT to assess entity security state of the entity prior to provisioning.

4 - Certificate Issuance Certification Authorities (CA’s) may require attestations prior to the issuance of certificates related to keypairs hosted at the entity. An EAT may be used as part of the certificate signing request (CSR).

5 - Proof-of-Possession: An EAT consumer may require an attestation as part of an accompanying proof-of-possession (PoP) application. More precisely, a PoP transaction is intended to provide to the recipient cryptographically-verifiable proof that the sender has possession of a key. This kind of attestation may be necessary to verify the security state of the entity storing the private key used in a PoP application.

$$\text{Claims-Set-Claims} \equiv \{ \text{intended-use-label} \rightarrow \text{intended-use-type} \}$$

intended-use-type = generic / registration / provisioning / csr / pop

generic = JC< "generic", 1 >
registration = JC< "registration", 2 >
provisioning = JC< "provisioning", 3 >
csr = JC< "csr", 4 >
pop = JC< "pop", 5 >

4.4. Including Keys

An EAT may include a cryptographic key such as a public key. The signing of the EAT binds the key to all the other claims in the token.
The purpose for inclusion of the key may vary by use case. For example, the key may be included as part of an IoT device onboarding protocol. When the FIDO protocol includes a public key in its attestation message, the key represents the binding of a user, device and Relying Party. This document describes how claims containing keys should be defined for the various use cases. It does not define specific claims for specific use cases.

Keys in CBOR format tokens SHOULD be the COSE_Key format [RFC8152] and keys in JSON format tokens SHOULD be the JSON Web Key format [RFC7517]. These two formats support many common key types. Their use avoids the need to decode other serialization formats. These two formats can be extended to support further key types through their IANA registries.

The general confirmation claim format [RFC8747], [RFC7800] may also be used. It provides key encryption. It also allows for inclusion by reference through a key ID. The confirmation claim format may employed in the definition of some new claim for a a particular use case.

When the actual confirmation claim is included in an EAT, this document associates no use case semantics other than proof of possession. Different EAT use cases may choose to associate further semantics. The key in the confirmation claim MUST be protected in the same way as the key used to sign the EAT. That is, the same, equivalent or better hardware defenses, access controls, key generation and such must be used.

5. Detached EAT Bundles

A detached EAT bundle is a structure to convey a fully-formed and signed token plus detached claims set that relate to that token. It is a top-level EAT message like a CWT or JWT. It can be occur any place that CWT or JWT messages occur. It may also be sent as a submodule.

A DEB has two main parts.

The first part is a full top-level token. This top-level token must have at least one submodule that is a detached digest. This top-level token may be either CBOR or JSON-encoded. It may be a CWT, or JWT but not a DEB. It may also be some future-defined token type. The same mechanism for distinguishing the type for nested token submodules is used here.

The second part is a map/object containing the detached Claims-Sets corresponding to the detached digests in the full token. When the
DEB is CBOR-encoded, each Claims-Set is wrapped in a byte string. When the DEB is JSON-encoded, each Claims-Set is base64url encoded. All the detached Claims-Sets MUST be encoded in the same format as the DEB. No mixing of encoding formats is allowed for the Claims-Sets in a DEB.

For CBOR-encoded DEBs, tag TBD602 can be used to identify it. The normal rules apply for use or non-use of a tag. When it is sent as a submodule, it is always sent as a tag to distinguish it from the other types of nested tokens.

The digests of the detached claims sets are associated with detached Claims-Sets by label/name. It is up to the constructor of the detached EAT bundle to ensure the names uniquely identify the detached claims sets. Since the names are used only in the detached EAT bundle, they can be very short, perhaps one byte.

DEB-Messages = DEB-Tagged-Message / DEB-Untagged-Message

DEB-Tagged-Message = #6.TBD(DEB-Untagged-Message)
DEB-Untagged-Message = Detached-EAT-Bundle

Detached-EAT-Bundle = [main-token : Nested-Token, detached-claims-sets: {+ tstr => JC<json-wrapped-claims-set, cbor-wrapped-claims-set> }]

json-wrapped-claims-set = base64-url-text
cbor-wrapped-claims-set = bstr .cbor Claims-Set

6. Endorsements and Verification Keys

The Verifier must possess the correct key when it performs the cryptographic part of an EAT verification (e.g., verifying the COSE/JOSE signature). This section describes several ways to identify the verification key. There is not one standard method.

The verification key itself may be a public key, a symmetric key or something complicated in the case of a scheme like Direct Anonymous Attestation (DAA).

RATS Architecture [RATS.Architecture] describes what is called an Endorsement. This is an input to the Verifier that is usually the
basis of the trust placed in an EAT and the Attester that generated it. It may contain the public key for verification of the signature on the EAT. It may contain Reference Values to which EAT claims are compared as part of the verification process. It may contain implied claims, those that are passed on to the Relying Party in Attestation Results.

There is not yet any standard format(s) for an Endorsement. One format that may be used for an Endorsement is an X.509 certificate. Endorsement data like Reference Values and implied claims can be carried in X.509 v3 extensions. In this use, the public key in the X.509 certificate becomes the verification key, so identification of the Endorsement is also identification of the verification key.

The verification key identification and establishment of trust in the EAT and the attester may also be by some other means than an Endorsement.

For the components (Attester, Verifier, Relying Party,...) of a particular end-end attestation system to reliably interoperate, its definition should specify how the verification key is identified. Usually, this will be in the profile document for a particular attestation system.

6.1. Identification Methods

Following is a list of possible methods of key identification. A specific attestation system may employ any one of these or one not listed here.

The following assumes Endorsements are X.509 certificates or equivalent and thus does not mention or define any identifier for Endorsements in other formats. If such an Endorsement format is created, new identifiers for them will also need to be created.

6.1.1. COSE/JWS Key ID

The COSE standard header parameter for Key ID (kid) may be used. See [RFC8152] and [RFC7515]

COSE leaves the semantics of the key ID open-ended. It could be a record locator in a database, a hash of a public key, an input to a KDF, an authority key identifier (AKI) for an X.509 certificate or other. The profile document should specify what the key ID’s semantics are.
6.1.2. JWS and COSE X.509 Header Parameters

COSE X.509 [COSE.X509.Draft] and JSON Web Signature [RFC7515] define several header parameters (x5t, x5u, ...) for referencing or carrying X.509 certificates any of which may be used.

The X.509 certificate may be an Endorsement and thus carrying additional input to the Verifier. It may be just an X.509 certificate, not an Endorsement. The same header parameters are used in both cases. It is up to the attestation system design and the Verifier to determine which.

6.1.3. CBOR Certificate COSE Header Parameters

Compressed X.509 and CBOR Native certificates are defined by CBOR Certificates [CBOR.Cert.Draft]. These are semantically compatible with X.509 and therefore can be used as an equivalent to X.509 as described above.

These are identified by their own header parameters (c5t, c5u, ...).

6.1.4. Claim-Based Key Identification

For some attestation systems, a claim may be re-used as a key identifier. For example, the UEID uniquely identifies the entity and therefore can work well as a key identifier or Endorsement identifier.

This has the advantage that key identification requires no additional bytes in the EAT and makes the EAT smaller.

This has the disadvantage that the unverified EAT must be substantially decoded to obtain the identifier since the identifier is in the COSE/JOSE payload, not in the headers.

6.2. Other Considerations

In all cases there must be some way that the verification key is itself verified or determined to be trustworthy. The key identification itself is never enough. This will always be by some out-of-band mechanism that is not described here. For example, the Verifier may be configured with a root certificate or a master key by the Verifier system administrator.

Often an X.509 certificate or an Endorsement carries more than just the verification key. For example, an X.509 certificate might have key usage constraints and an Endorsement might have Reference Values. When this is the case, the key identifier must be either a protected
header or in the payload such that it is cryptographically bound to the EAT. This is in line with the requirements in section 6 on Key Identification in JSON Web Signature [RFC7515].

7. Profiles

This EAT specification does not guarantee that implementations of it will interoperate. The variability in this specification is necessary to accommodate the widely varying use cases. An EAT profile narrows the specification for a specific use case. An ideal EAT profile will guarantee interoperability.

The profile can be named in the token using the profile claim described in Section 4.3.3.

A profile can apply to Attestation Evidence or to Attestation Results or both.

7.1. Format of a Profile Document

A profile document doesn’t have to be in any particular format. It may be simple text, something more formal or a combination.

In some cases CDDL may be created that replaces CDDL in this or other document to express some profile requirements. For example, to require the altitude data item in the location claim, CDDL can be written that replicates the location claim with the altitude no longer optional.

7.2. List of Profile Issues

The following is a list of EAT, CWT, JWS, COSE, JOSE and CBOR options that a profile should address.

7.2.1. Use of JSON, CBOR or both

The profile should indicate whether the token format should be CBOR, JSON, both or even some other encoding. If some other encoding, a specification for how the CDDL described here is serialized in that encoding is necessary.

This should be addressed for the top-level token and for any nested tokens. For example, a profile might require all nested tokens to be of the same encoding of the top level token.
7.2.2. CBOR Map and Array Encoding

The profile should indicate whether definite-length arrays/maps, indefinite-length arrays/maps or both are allowed. A good default is to allow only definite-length arrays/maps.

An alternate is to allow both definite and indefinite-length arrays/maps. The decoder should accept either. Encoders that need to fit on very small hardware or be actually implement in hardware can use indefinite-length encoding.

This applies to individual EAT claims, CWT and COSE parts of the implementation.

7.2.3. CBOR String Encoding

The profile should indicate whether definite-length strings, indefinite-length strings or both are allowed. A good default is to allow only definite-length strings. As with map and array encoding, allowing indefinite-length strings can be beneficial for some smaller implementations.

7.2.4. CBOR Preferred Serialization

The profile should indicate whether encoders must use preferred serialization. The profile should indicate whether decoders must accept non-preferred serialization.

7.2.5. COSE/JOSE Protection

COSE and JOSE have several options for signed, MACed and encrypted messages. JWT may use the JOSE NULL protection option. It is possible to implement no protection, sign only, MAC only, sign then encrypt and so on. All combinations allowed by COSE, JOSE, JWT, and CWT are allowed by EAT.

The profile should list the protections that must be supported by all decoders implementing the profile. The encoders them must implement a subset of what is listed for the decoders, perhaps only one.

Implementations may choose to sign or MAC before encryption so that the implementation layer doing the signing or MACing can be the smallest. It is often easier to make smaller implementations more secure, perhaps even implementing in solely in hardware. The key material for a signature or MAC is a private key, while for encryption it is likely to be a public key. The key for encryption requires less protection.
7.2.6. COSE/JOSE Algorithms

The profile document should list the COSE algorithms that a Verifier must implement. The Attester will select one of them. Since there is no negotiation, the Verifier should implement all algorithms listed in the profile. If detached submodules are used, the COSE algorithms allowed for their digests should also be in the profile.

7.2.7. DEB Support

A Detached EAT Bundle Section 5 is a special case message that will not often be used. A profile may prohibit its use.

7.2.8. Verification Key Identification

Section 6 describes a number of methods for identifying a verification key. The profile document should specify one of these or one that is not described. The ones described in this document are only roughly described. The profile document should go into the full detail.

7.2.9. Endorsement Identification

Similar to, or perhaps the same as Verification Key Identification, the profile may wish to specify how Endorsements are to be identified. However note that Endorsement Identification is optional, whereas key identification is not.

7.2.10. Freshness

Just about every use case will require some means of knowing the EAT is recent enough and not a replay of an old token. The profile should describe how freshness is achieved. The section on Freshness in [RATS.Architecture] describes some of the possible solutions to achieve this.

7.2.11. Required Claims

The profile can list claims whose absence results in Verification failure.

7.2.12. Prohibited Claims

The profile can list claims whose presence results in Verification failure.
7.2.13. Additional Claims

The profile may describe entirely new claims. These claims can be required or optional.

7.2.14. Refined Claim Definition

The profile may lock down optional aspects of individual claims. For example, it may require altitude in the location claim, or it may require that HW Versions always be described using EAN-13.

7.2.15. CBOR Tags

The profile should specify whether the token should be a CWT Tag or not.

When COSE protection is used, the profile should specify whether COSE tags are used or not. Note that RFC 8392 requires COSE tags be used in a CWT tag.

Often a tag is unnecessary because the surrounding or carrying protocol identifies the object as an EAT.

7.2.16. Manifests and Software Evidence Claims

The profile should specify which formats are allowed for the manifests and software evidence claims. The profile may also go on to say which parts and options of these formats are used, allowed and prohibited.

8. Encoding and Collected CDDL

An EAT is fundamentally defined using CDDL. This document specifies how to encode the CDDL in CBOR or JSON. Since CBOR can express some things that JSON can't (e.g., tags) or that are expressed differently (e.g., labels) there is some CDDL that is specific to the encoding format.

8.1. Claims-Set and CDDL for CWT and JWT

CDDL was not used to define CWT or JWT. It was not available at the time.

This document defines CDDL for both CWT and JWT. This document does not change the encoding or semantics of anything in a CWT or JWT.

A Claims-Set is the central data structure for EAT, CWT and JWT. It holds all the claims and is the structure that is secured by signing
or other means. It is not possible to define EAT, CWT, or JWT in CDDL without it. The CDDL definition of Claims-Set here is applicable to EAT, CWT and JWT.

This document specifies how to encode a Claims-Set in CBOR or JSON.

With the exception of nested tokens and some other externally defined structures (e.g., SWIDs) an entire Claims-Set must be in encoded in either CBOR or JSON, never a mixture.

CDDL for the seven claims defined by [RFC8392] and [RFC7519] is included here.

8.2. Encoding Data Types

This makes use of the types defined in [RFC8610] Appendix D, Standard Prelude.

8.2.1. Common Data Types

time-int is identical to the epoch-based time, but disallows floating-point representation.

The OID encoding from [RFC9090] is used without the tag number in CBOR-encoded tokens. In JSON tokens OIDs are a text string in the common form of "nn.nn.nn...".

Unless explicitly indicated, URIs are not the URI tag defined in [RFC8949]. They are just text strings that contain a URI.

time-int = #6.1(int)

binary-data = JC< base64-url-text, bstr>

base64-url-text = tstr .regexp "[A-Za-z0-9_=-]+"

general-oid = JC< json-oid, "oid" >

json-oid = tstr .regexp "[0-9.]+"

general-uri = JC< text, "uri" >

8.2.2. JSON Interoperability

JSON should be encoded per [RFC8610] Appendix E. In addition, the following CDDL types are encoded in JSON as follows:

- bstr - must be base64url encoded
time - must be encoded as NumericDate as described section 2 of [RFC7519].

string-or-uri - must be encoded as StringOrURI as described section 2 of [RFC7519].

uri - must be a URI [RFC3986].

oid - encoded as a string using the well established dotted-decimal notation (e.g., the text "1.2.250.1").

The CDDL generic "JC< >" is used in most places where there is a variance between CBOR and JSON. The first argument is the CDDL for JSON and the second is CDDL for CBOR.

8.2.3. Labels

Map labels, including Claims-Keys and Claim-Names, and enumerated-type values are always integers when encoding in CBOR and strings when encoding in JSON. There is an exception to this for naming submodules and detached claims sets in a DEB. These are strings in CBOR.

The CDDL in most cases gives both the integer label and the string label as it is not convenient to have conditional CDDL for such.

8.3. CBOR Interoperability

CBOR allows data items to be serialized in more than one form. If the sender uses a form that the receiver can’t decode, there will not be interoperability.

This specification gives no blanket requirements to narrow CBOR serialization for all uses of EAT. This allows individual uses to tailor serialization to the environment. It also may result in EAT implementations that don’t interoperate.

One way to guarantee interoperability is to clearly specify CBOR serialization in a profile document. See Section 7 for a list of serialization issues that should be addressed.

EAT will be commonly used where the entity generating the attestation is constrained and the receiver/Verifier of the attestation is a capacious server. Following is a set of serialization requirements that work well for that use case and are guaranteed to interoperate. Use of this serialization is recommended where possible, but not required. An EAT profile may just reference the following section rather than spell out serialization details.
8.3.1. EAT Constrained Device Serialization

- Preferred serialization described in section 4.1 of [RFC8949] is not required. The EAT decoder must accept all forms of number serialization. The EAT encoder may use any form it wishes.

- The EAT decoder must accept indefinite length arrays and maps as described in section 3.2.2 of [RFC8949]. The EAT encoder may use indefinite length arrays and maps if it wishes.

- The EAT decoder must accept indefinite length strings as described in section 3.2.3 of [RFC8949]. The EAT encoder may use indefinite length strings if it wishes.

- Sorting of maps by key is not required. The EAT decoder must not rely on sorting.

- Deterministic encoding described in Section 4.2 of [RFC8949] is not required.

- Basic validity described in section 5.3.1 of [RFC8949] must be followed. The EAT encoder must not send duplicate map keys/labels or invalid UTF-8 strings.

8.4. Collected CDDL

8.4.1. Payload CDDL

This CDDL defines all the EAT Claims that are added to the main definition of a Claim-Set in Appendix D. Claim-Set is the payload for CWT, JWT and potentially other token types. This is for both CBOR and JSON. When there is variation between CBOR and JSON, the JC<> CDDL generic defined in Appendix D.

This CDDL uses, but doesn’t define Nested-Token because its definition varies between CBOR and JSON and the JC<> generic can’t be used to define it. Nested-Token is the one place that that a CBOR token can be nested inside a JSON token and vice versa. Nested-Token is defined in the following sections.

time-int = #6.1(int)

binary-data = JC< base64-url-text, bstr>

base64-url-text = tstr .regexp "[A-Za-z0-9_-]+"

general-oid = JC< json-oid, ~oid >
json-oid = tstr .regexp \[0-9\./]+\]

9. IANA Considerations

9.1. Reuse of CBOR and JSON Web Token (CWT and JWT) Claims Registries

Claims defined for EAT are compatible with those of CWT and JWT so the CWT and JWT Claims Registries, [IANA.CWT.Claims] and [IANA.JWT.Claims], are re used. No new IANA registry is created.

All EAT claims defined in this document are placed in both registries. All new EAT claims defined subsequently should be placed in both registries.

9.2. Claim Characteristics

The following is design guidance for creating new EAT claims, particularly those to be registered with IANA.

Much of this guidance is generic and could also be considered when designing new CWT or JWT claims.

9.2.1. Interoperability and Relying Party Orientation

It is a broad goal that EATs can be processed by Relying Parties in a general way regardless of the type, manufacturer or technology of the device from which they originate. It is a goal that there be general-purpose verification implementations that can verify tokens for large numbers of use cases with special cases and configurations for different device types. This is a goal of interoperability of...
the semantics of claims themselves, not just of the signing, encoding and serialization formats.

This is a lofty goal and difficult to achieve broadly requiring careful definition of claims in a technology neutral way. Sometimes it will be difficult to design a claim that can represent the semantics of data from very different device types. However, the goal remains even when difficult.

9.2.2. Operating System and Technology Neutral

Claims should be defined such that they are not specific to an operating system. They should be applicable to multiple large high-level operating systems from different vendors. They should also be applicable to multiple small embedded operating systems from multiple vendors and everything in between.

Claims should not be defined such that they are specific to a SW environment or programming language.

Claims should not be defined such that they are specific to a chip or particular hardware. For example, they should not just be the contents of some HW status register as it is unlikely that the same HW status register with the same bits exists on a chip of a different manufacturer.

The boot and debug state claims in this document are an example of a claim that has been defined in this neutral way.

9.2.3. Security Level Neutral

Many use cases will have EATs generated by some of the most secure hardware and software that exists. Secure Elements and smart cards are examples of this. However, EAT is intended for use in low-security use cases the same as high-security use case. For example, an app on a mobile device may generate EATs on its own.

Claims should be defined and registered on the basis of whether they are useful and interoperable, not based on security level. In particular, there should be no exclusion of claims because they are just used only in low-security environments.

9.2.4. Reuse of Extant Data Formats

Where possible, claims should use already standardized data items, identifiers and formats. This takes advantage of the expertise put into creating those formats and improves interoperability.
Often extant claims will not be defined in an encoding or serialization format used by EAT. It is preferred to define a CBOR and JSON format for them so that EAT implementations do not require a plethora of encoders and decoders for serialization formats.

In some cases, it may be better to use the encoding and serialization as is. For example, signed X.509 certificates and CRLs can be carried as-is in a byte string. This retains interoperability with the extensive infrastructure for creating and processing X.509 certificates and CRLs.

9.2.5. Proprietary Claims

EAT allows the definition and use of proprietary claims.

For example, a device manufacturer may generate a token with proprietary claims intended only for verification by a service offered by that device manufacturer. This is a supported use case.

In many cases proprietary claims will be the easiest and most obvious way to proceed, however for better interoperability, use of general standardized claims is preferred.

9.3. Claims Registered by This Document

This specification adds the following values to the "JSON Web Token Claims" registry established by [RFC7519] and the "CBOR Web Token Claims Registry" established by [RFC8392]. Each entry below is an addition to both registries (except for the nonce claim which is already registered for JWT, but not registered for CWT).

The "Claim Description", "Change Controller" and "Specification Documents" are common and equivalent for the JWT and CWT registries. The "Claim Key" and "Claim Value Types(s)" are for the CWT registry only. The "Claim Name" is as defined for the CWT registry, not the JWT registry. The "JWT Claim Name" is equivalent to the "Claim Name" in the JWT registry.

9.3.1. Claims for Early Assignment

RFC Editor: in the final publication this section should be combined with the following section as it will no longer be necessary to distinguish claims with early assignment. Also, the following paragraph should be removed.

The claims in this section have been (requested for / given) early assignment according to [RFC7120]. They have been assigned values and registered before final publication of this document. While
their semantics is not expected to change in final publication, it is possible that they will. The JWT Claim Names and CWT Claim Keys are not expected to change.

In draft -06 an early allocation was described. The processing of that early allocation was never correctly completed. This early allocation assigns different numbers for the CBOR claim labels. This early allocation will presumably complete correctly.

- Claim Name: Nonce
  - Claim Description: Nonce
  - JWT Claim Name: "nonce" (already registered for JWT)
  - Claim Key: TBD (requested value 10)
  - Claim Value Type(s): byte string
  - Change Controller: IESG
  - Specification Document(s): [OpenIDConnectCore], *this document*

- Claim Name: UEID
  - Claim Description: The Universal Entity ID
  - JWT Claim Name: "ueid"
  - CWT Claim Key: TBD (requested value 256)
  - Claim Value Type(s): byte string
  - Change Controller: IESG
  - Specification Document(s): *this document*

- Claim Name: SUEIDs
  - Claim Description: Semi-permanent UEIDs
  - JWT Claim Name: "sueids"
  - CWT Claim Key: TBD (requested value 257)
  - Claim Value Type(s): map
  - Change Controller: IESG
- Specification Document(s): *this document*
- Claim Name: Hardware OEMID
- Claim Description: Hardware OEM ID
- JWT Claim Name: "oemid"
- Claim Key: TBD (requested value 258)
- Claim Value Type(s): byte string or integer
- Change Controller: IESG

- Specification Document(s): *this document*
- Claim Name: Hardware Model
- Claim Description: Model identifier for hardware
- JWT Claim Name: "hwmodel"
- Claim Key: TBD (requested value 259)
- Claim Value Type(s): byte string
- Change Controller: IESG

- Specification Document(s): *this document*
- Claim Name: Hardware Version
- Claim Description: Hardware Version Identifier
- JWT Claim Name: "hwversion"
- Claim Key: TBD (requested value 260)
- Claim Value Type(s): array
- Change Controller: IESG

- Specification Document(s): *this document*
- Claim Name: Secure Boot
- Claim Description: Indicate whether the boot was secure
o JWT Claim Name: "secboot"
 o Claim Key: 262
 o Claim Value Type(s): Boolean
 o Change Controller: IESG
 o Specification Document(s): *this document*

o Claim Name: Debug Status
 o Claim Description: Indicate status of debug facilities
 o JWT Claim Name: "dbgstat"
 o Claim Key: 263
 o Claim Value Type(s): integer or string
 o Change Controller: IESG
 o Specification Document(s): *this document*

o Claim Name: Location
 o Claim Description: The geographic location
 o JWT Claim Name: "location"
 o Claim Key: TBD (requested value 264)
 o Claim Value Type(s): map
 o Change Controller: IESG
 o Specification Document(s): *this document*

o Claim Name: Profile
 o Claim Description: Indicates the EAT profile followed
 o JWT Claim Name: "eat_profile"
 o Claim Key: TBD (requested value 265)
 o Claim Value Type(s): URI or OID
9.3.2. To be Assigned Claims

(Early assignment is NOT requested for these claims. Implementers should be aware they may change)

- **Claim Name:** Security Level
- **Claim Description:** Characterization of the security of an Attester or submodule
  - **JWT Claim Name:** "secllevel"
  - **Claim Key:** TBD
  - **Claim Value Type(s):** integer or string
  - **Change Controller:** IESG
  - **Specification Document(s):** *this document*

- **Claim Name:** Uptime
  - **Claim Description:** Uptime
  - **JWT Claim Name:** "uptime"
  - **Claim Key:** TBD
  - **Claim Value Type(s):** unsigned integer
- Change Controller: IESG
- Specification Document(s): *this document*
- Claim Name: Boot Seed
- Claim Description: Identifies a boot cycle
- JWT Claim Name: "bootseed"
- Claim Key: TBD
- Claim Value Type(s): bytes
- Change Controller: IESG
- Specification Document(s): *this document*
- Claim Name: Intended Use
- Claim Description: Indicates intended use of the EAT
- JWT Claim Name: "intuse"
- Claim Key: TBD
- Claim Value Type(s): integer or string
- Change Controller: IESG
- Specification Document(s): *this document*
- Claim Name: DLOAs
- Claim Description: Certifications received as Digital Letters of Approval
- JWT Claim Name: "dloas"
- Claim Key: TBD
- Claim Value Type(s): array
- Change Controller: IESG
- Specification Document(s): *this document*
- Claim Name: SW Name
o Claim Description: The name of the SW running in the entity
  o JWT Claim Name: "swname"
  o Claim Key: TBD
  o Claim Value Type(s): map
  o Change Controller: IESG
  o Specification Document(s): *this document*

o Claim Name: SW Version
  o Claim Description: The version of SW running in the entity
  o JWT Claim Name: "swversion"
  o Claim Key: TBD
  o Claim Value Type(s): map
  o Change Controller: IESG
  o Specification Document(s): *this document*

o Claim Name: SW Manifests
  o Claim Description: Manifests describing the SW installed on the entity
  o JWT Claim Name: "manifests"
  o Claim Key: TBD
  o Claim Value Type(s): array
  o Change Controller: IESG
  o Specification Document(s): *this document*

o Claim Name: SW Evidence
  o Claim Description: Measurements of the SW, memory configuration and such on the entity
  o JWT Claim Name: "swevidence"
9.3.3. Version Schemes Registered by this Document

IANA is requested to register a new value in the "Software Tag Version Scheme Values" established by [CoSWID].

The new value is a version scheme a 13-digit European Article Number [EAN-13]. An EAN-13 is also known as an International Article Number or most commonly as a bar code. This version scheme is the ASCII text representation of EAN-13 digits, the same ones often printed with a bar code. This version scheme must comply with the EAN allocation and assignment rules. For example, this requires the manufacturer to obtain a manufacture code from GS1.

+-------+---------------------+---------------+
| Index | Version Scheme Name | Specification |
+-------+---------------------+---------------+
| 5     | ean-13              | This document |
+-------+---------------------+---------------+

9.3.4. UEID URN Registered by this Document

IANA is requested to register the following new subtypes in the "DEV URN Subtypes" registry under "Device Identification". See [RFC9039].
9.3.5. Tag for Detached EAT Bundle

In the registry [IANA.cbor-tags], IANA is requested to allocate the following tag from the FCFS space, with the present document as the specification reference.

<table>
<thead>
<tr>
<th>Tag</th>
<th>Data Items</th>
<th>Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBD602</td>
<td>array</td>
<td>Detached EAT Bundle Section 5</td>
</tr>
</tbody>
</table>

10. Privacy Considerations

Certain EAT claims can be used to track the owner of an entity and therefore, implementations should consider providing privacy-preserving options dependent on the intended usage of the EAT. Examples would include suppression of location claims for EAT’s provided to unauthenticated consumers.

10.1. UEID and SUEID Privacy Considerations

A UEID is usually not privacy-preserving. Any set of Relying Parties that receives tokens that happen to be from a particular entity will be able to know the tokens are all from the same entity and be able to track it.

Thus, in many usage situations UEID violates governmental privacy regulation. In other usage situations a UEID will not be allowed for certain products like browsers that give privacy for the end user. It will often be the case that tokens will not have a UEID for these reasons.

An SUEID is also usually not privacy-preserving. In some cases it may have fewer privacy issues than a UEID depending on when and how and when it is generated.

There are several strategies that can be used to still be able to put UEIDs and SUEIDs in tokens:
The entity obtains explicit permission from the user of the entity to use the UEID/SUEID. This may be through a prompt. It may also be through a license agreement. For example, agreements for some online banking and brokerage services might already cover use of a UEID/SUEID.

The UEID/SUEID is used only in a particular context or particular use case. It is used only by one Relying Party.

The entity authenticates the Relying Party and generates a derived UEID/SUEID just for that particular Relying Party. For example, the Relying Party could prove their identity cryptographically to the entity, then the entity generates a UEID just for that Relying Party by hashing a proofed Relying Party ID with the main entity UEID/SUEID.

Note that some of these privacy preservation strategies result in multiple UEIDs and SUEIDs per entity. Each UEID/SUEID is used in a different context, use case or system on the entity. However, from the view of the Relying Party, there is just one UEID and it is still globally universal across manufacturers.

10.2. Location Privacy Considerations

Geographic location is most always considered personally identifiable information. Implementers should consider laws and regulations governing the transmission of location data from end user devices to servers and services. Implementers should consider using location management facilities offered by the operating system on the entity generating the attestation. For example, many mobile phones prompt the user for permission when before sending location data.

10.3. Replay Protection and Privacy

EAT offers 2 primary mechanisms for token replay protection (also sometimes known as token "freshness"): the cti/jti claim and the nonce claim. The cti/jti claim in a CWT/JWT is a field that may be optionally included in the EAT and is in general derived on the same device in which the entity is instantiated. The nonce claim is based on a value that is usually derived remotely (outside of the entity). These claims can be used to extract and convey personally-identifying information either inadvertently or by intention. For instance, an implementor may choose a cti that is equivalent to a username associated with the device (e.g., account login). If the token is inspected by a 3rd-party then this information could be used to identify the source of the token or an account associated with the token (e.g., if the account name is used to derive the nonce). In order to avoid the conveyance of privacy-related information in
either the cti/jti or nonce claims, these fields should be derived using a salt that originates from a true and reliable random number generator or any other source of randomness that would still meet the target system requirements for replay protection.

11. Security Considerations

The security considerations provided in Section 8 of [RFC8392] and Section 11 of [RFC7519] apply to EAT in its CWT and JWT form, respectively. In addition, implementors should consider the following.

11.1. Key Provisioning

Private key material can be used to sign and/or encrypt the EAT, or can be used to derive the keys used for signing and/or encryption. In some instances, the manufacturer of the entity may create the key material separately and provision the key material in the entity itself. The manufacture of any entity that is capable of producing an EAT should take care to ensure that any private key material be suitably protected prior to provisioning the key material in the entity itself. This can require creation of key material in an enclave (see [RFC4949] for definition of "enclave"), secure transmission of the key material from the enclave to the entity using an appropriate protocol, and persistence of the private key material in some form of secure storage to which (preferably) only the entity has access.

11.1.1. Transmission of Key Material

Regarding transmission of key material from the enclave to the entity, the key material may pass through one or more intermediaries. Therefore some form of protection ("key wrapping") may be necessary. The transmission itself may be performed electronically, but can also be done by human courier. In the latter case, there should be minimal to no exposure of the key material to the human (e.g. encrypted portable memory). Moreover, the human should transport the key material directly from the secure enclave where it was created to a destination secure enclave where it can be provisioned.

11.2. Transport Security

As stated in Section 8 of [RFC8392], "The security of the CWT relies upon on the protections offered by COSE". Similar considerations apply to EAT when sent as a CWT. However, EAT introduces the concept of a nonce to protect against replay. Since an EAT may be created by an entity that may not support the same type of transport security as the consumer of the EAT, intermediaries may be required to bridge...
communications between the entity and consumer. As a result, it is
RECOMMENDED that both the consumer create a nonce, and the entity
leverage the nonce along with COSE mechanisms for encryption and/or
signing to create the EAT.

Similar considerations apply to the use of EAT as a JWT. Although
the security of a JWT leverages the JSON Web Encryption (JWE) and
JSON Web Signature (JWS) specifications, it is still recommended to
make use of the EAT nonce.

11.3. Multiple EAT Consumers

In many cases, more than one EAT consumer may be required to fully
verify the entity attestation. Examples include individual consumers
for nested EATs, or consumers for individual claims with an EAT.
When multiple consumers are required for verification of an EAT, it
is important to minimize information exposure to each consumer. In
addition, the communication between multiple consumers should be
secure.

For instance, consider the example of an encrypted and signed EAT
with multiple claims. A consumer may receive the EAT (denoted as the
"receiving consumer"), decrypt its payload, verify its signature, but
then pass specific subsets of claims to other consumers for
evaluation ("downstream consumers"). Since any COSE encryption will
be removed by the receiving consumer, the communication of claim
subsets to any downstream consumer should leverage a secure protocol
(e.g. one that uses transport-layer security, i.e. TLS).

However, assume the EAT of the previous example is hierarchical and
each claim subset for a downstream consumer is created in the form of
a nested EAT. Then transport security between the receiving and
downstream consumers is not strictly required. Nevertheless,
downstream consumers of a nested EAT should provide a nonce unique to
the EAT they are consuming.

Appendix A. Examples

Most examples are shown as just a Claims-Set that would be a payload for a CWT, JWT, DEB or future token types. It is shown this way because the payload is all the claims, the most interesting part and showing full tokens makes it harder to show the claims.

Some examples of full tokens are also given.

WARNING: These examples use tag and label numbers not yet assigned by IANA.

A.1. Payload Examples

A.1.1. Simple TEE Attestation

This is a simple attestation of a TEE that includes a manifest that is a payload CoSWID to describe the TEE’s software.
/ This is an EAT payload that describes a simple TEE. /
{
  / nonce / 10: h'948f8860d13a463e',
  / security-level / 261: 2, / restricted /
  / secure-boot / 262: true,
  / debug-status / 263: 2, / disabled-since-boot /
  / manifests / 273: [
    121, / CoAP Content ID. A /
    / made up one until one /
    / is assigned for CoSWID /
    / This is byte-string wrapped /
    / payload CoSWID. It gives the TEE /
    / software name, the version and /
    / the name of the file it is in. /
    / (0: "3a24",
    / 12: 1, /
    /  1: "Acme TEE OS",
    / 13: "3.1.4",
    /  2: [{31: "Acme TEE OS", 33: 1}, /
    /    {31: "Acme TEE OS", 33: 2}], /
    /  6: {
    /  17: {
    /  24: "acme_tee_3.exe"
    / }
    / }
    / h' a60064336132340c01016b
41636d6520544545204f53182101a2181f6b41636d6520544545
204f53182101a2181f6b41636d6520544545
4545204f5318210206a111a118186e61
636d655f7465655f332e57865'
    ]
  ]
}
A payload CoSWID created by the SW vendor. All this really does is name the TEE SW, its version and lists the one file that makes up the TEE.

```json
1398229316({
  / Unique CoSWID ID / 0: "3a24",
  / tag-version / 12: 1,
  / software-name / 1: "Acme TEE OS",
  / software-version / 13: "3.1.4",
  / entity / 2: [
    / entity-name / 31: "Acme TEE OS",
    / role / 33: 1 / tag-creator /
  ],
  / entity-name / 31: "Acme TEE OS",
  / role / 33: 2 / software-creator /
},
/ payload /
  6: {
    / ...file / 17: {
      / ...fs-name / 24: "acme_tee_3.exe"
    }
  }
})
```

A.1.2. Submodules for Board and Device
This example shows use of submodules to give information about the chip, board and overall device. The main attestation is associated with the chip with the CPU and running the main OS. It is what has the keys and produces the token.

The board is made by a different vendor than the chip. Perhaps it is some generic IoT board.

The device is some specific appliance that is made by a different vendor than either the chip or the board.

Here the board and device submodules aren’t the typical target environments as described by the RATS architecture document, but they are a valid use of submodules.

```json
{
  "nonce": "h'\text{\texttt{948f8860d13a463e8e'}}",
  "UEID": "h'\text{\texttt{0198f50a4ff6c05861c8860d13a638ea'}}",

                / Hash of board module name /,
        },
        A submodule to hold claims about the overall device /
        "device" : {
            HW OEM ID : 258: 61234, / PEN Format OEM ID /
            HW Model ID : 259: h'ee80f5a66c1fb9742999a8fdab930893'
                / Hash of board module name /,
        }
    }
}
```
A.1.6. EAT Produced by Attestation Hardware Block

/ This is an example of a token produced by a HW block /
/ purpose-built for attestation. Only the nonce claim changes /
/ from one attestation to the next as the rest either come /
/ directly from the hardware or from one-time-programmable memory /
/ (e.g. a fuse). 47 bytes encoded in CBOR (8 byte nonce, 16 byte /
/ UEID). /

{  
  nonce / 10: h'948f8860d13a463e',  
  UEID / 256: h'0198f50a4ff6c05861c8860d13a638ea',  
  OEMID / 258: 64242, / Private Enterprise Number /  
  security-level / 261: 3, / hardware level security /  
  secure-boot / 262: true,  
  debug-status / 263: 3, / disabled-permanently /  
  HW version / 260: [ "3.1", 1 ] / Type is multipartnumeric /  
}

A.1.7. Key / Key Store Attestation

/ This is an attestation of a public key and the key store /
/ implementation that protects and manages it. The key store /
/ implementation is in a security-oriented execution /
/ environment separate from the high-level OS, for example a /
/ TEE. The key store is the Attester. /

/ There is some attestation of the high-level OS, just version /
/ and boot & debug status. It is a Claims-Set submodule because/  
/ it has lower security level than the key store. The key /
/ store's implementation has access to info about the HLOS, so /
/ it is able to include it. /

/ A key and an indication of the user authentication given to /
/ allow access to the key is given. The labels for these are /
/ in the private space since this is just a hypothetical /
/ example, not part of a standard protocol. /

/ This is similar to Android Key Attestation. /

{

A.1.9. Attestation Results in JSON format

This is a JSON-format payload that might be the output of a Verifier that evaluated the IoT Attestation example immediately above.

This particular Verifier knows enough about the TEE Attester to be able to pass claims like security level directly through to the Relying Party. The Verifier also knows the Reference Values for the measured SW components and is able to check them. It informs the Relying Party that they were correct in the swresults claim.

"Trustus Verifications" is the name of the services that verifies the SW component measurements.

    AB233787' / signature / ] ) )
A.2.2. Detached EAT Bundle

In this DEB main token is produced by a HW attestation block. The detached Claims-Set is produced by a TEE and is largely identical to the Simple TEE examples above. The TEE digests its Claims-Set and feeds that digest to the HW block.

In a better example the attestation produced by the HW block would be a CWT and thus signed and secured by the HW block. Since the signature covers the digest from the TEE that Claims-Set is also secured.

The DEB itself can be assembled by untrusted SW.
/ This is a detached EAT bundle (DEB) tag. / 
/ Note that 602, the tag identifying a DEB is not yet registered with IANA /

]
```

Appendix B. UEID Design Rationale
B.1. Collision Probability

This calculation is to determine the probability of a collision of UEIDs given the total possible entity population and the number of entities in a particular entity management database.

Three different sized databases are considered. The number of devices per person roughly models non-personal devices such as traffic lights, devices in stores they shop in, facilities they work in and so on, even considering individual light bulbs. A device may have individually attested subsystems, for example parts of a car or a mobile phone. It is assumed that the largest database will have at most 10% of the world’s population of devices. Note that databases that handle more than a trillion records exist today.

The trillion-record database size models an easy-to-imagine reality over the next decades. The quadrillion-record database is roughly at the limit of what is imaginable and should probably be accommodated. The 100 quadrillion database is highly speculative perhaps involving nanorobots for every person, livestock animal and domesticated bird. It is included to round out the analysis.

Note that the items counted here certainly do not have IP address and are not individually connected to the network. They may be connected to internal buses, via serial links, Bluetooth and so on. This is not the same problem as sizing IP addresses.

<table>
<thead>
<tr>
<th>People</th>
<th>Devices / Person</th>
<th>Subsystems / Device</th>
<th>Database Portion</th>
<th>Database Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 billion</td>
<td>100</td>
<td>10</td>
<td>10%</td>
<td>trillion (10^12)</td>
</tr>
<tr>
<td>10 billion</td>
<td>100,000</td>
<td>10</td>
<td>10%</td>
<td>quadrillion (10^15)</td>
</tr>
<tr>
<td>100 billion</td>
<td>1,000,000</td>
<td>10</td>
<td>10%</td>
<td>quadrillion (10^17)</td>
</tr>
</tbody>
</table>

This is conceptually similar to the Birthday Problem where \( m \) is the number of possible birthdays, always 365, and \( k \) is the number of people. It is also conceptually similar to the Birthday Attack where collisions of the output of hash functions are considered.

The proper formula for the collision calculation is
\[ p = 1 - e^{-k^2/(2n)} \]

\[ p \quad \text{Collision Probability} \]
\[ n \quad \text{Total possible population} \]
\[ k \quad \text{Actual population} \]

However, for the very large values involved here, this formula requires floating point precision higher than commonly available in calculators and SW so this simple approximation is used. See [BirthdayAttack].

\[ p = k^2 / 2n \]

For this calculation:

\[ p \quad \text{Collision Probability} \]
\[ n \quad \text{Total population based on number of bits in UEID} \]
\[ k \quad \text{Population in a database} \]

<table>
<thead>
<tr>
<th>Database Size</th>
<th>128-bit UEID</th>
<th>192-bit UEID</th>
<th>256-bit UEID</th>
</tr>
</thead>
<tbody>
<tr>
<td>trillion (10^12)</td>
<td>2 * 10^-15</td>
<td>8 * 10^-35</td>
<td>5 * 10^-55</td>
</tr>
<tr>
<td>quadrillion (10^15)</td>
<td>2 * 10^-09</td>
<td>8 * 10^-29</td>
<td>5 * 10^-49</td>
</tr>
<tr>
<td>100 quadrillion</td>
<td>2 * 10^-05</td>
<td>8 * 10^-25</td>
<td>5 * 10^-45</td>
</tr>
</tbody>
</table>

Next, to calculate the probability of a collision occurring in one year’s operation of a database, it is assumed that the database size is in a steady state and that 10% of the database changes per year. For example, a trillion record database would have 100 billion states per year. Each of those states has the above calculated probability of a collision.

This assumption is a worst-case since it assumes that each state of the database is completely independent from the previous state. In reality this is unlikely as state changes will be the addition or deletion of a few records.

The following tables gives the time interval until there is a probability of a collision based on there being one tenth the number of states per year as the number of records in the database.
\[
t = \frac{1}{\left(\frac{k}{10}\right) \cdot p}
\]

t \hspace{1em} \text{Time until a collision} \\
p \hspace{1em} \text{Collision probability for UEID size} \\
k \hspace{1em} \text{Database size}

<table>
<thead>
<tr>
<th>Database Size</th>
<th>128-bit UEID</th>
<th>192-bit UEID</th>
<th>256-bit UEID</th>
</tr>
</thead>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Clearly, 128 bits is enough for the near future thus the requirement that UEIDs be a minimum of 128 bits.

There is no requirement for 256 bits today as quadrillion-record databases are not expected in the near future and because this time-to-collision calculation is a very worst case. A future update of the standard may increase the requirement to 256 bits, so there is a requirement that implementations be able to receive 256-bit UEIDs.

B.2. No Use of UUID

A UEID is not a UUID [RFC4122] by conscious choice for the following reasons.

UUIDs are limited to 128 bits which may not be enough for some future use cases.

Today, cryptographic-quality random numbers are available from common CPUs and hardware. This hardware was introduced between 2010 and 2015. Operating systems and cryptographic libraries give access to this hardware. Consequently, there is little need for implementations to construct such random values from multiple sources on their own.

Version 4 UUIDs do allow for use of such cryptographic-quality random numbers, but do so by mapping into the overall UUID structure of time and clock values. This structure is of no value here yet adds complexity. It also slightly reduces the number of actual bits with entropy.

UUIDs seem to have been designed for scenarios where the implementor does not have full control over the environment and uniqueness has to be constructed from identifiers at hand. UEID takes the view that
hardware, software and/or manufacturing process directly implement UEID in a simple and direct way. It takes the view that cryptographic quality random number generators are readily available as they are implemented in commonly used CPU hardware.

Appendix C. EAT Relation to IEEE.802.1AR Secure Device Identity (DevID)

This section describes several distinct ways in which an IEEE IDevID [IEEE.802.1AR] relates to EAT, particularly to UEID and SUEID.

[IEEE.802.1AR] orients around the definition of an implementation called a "DevID Module." It describes how IDevIDs and LDevIDs are stored, protected and accessed using a DevID Module. A particular level of defense against attack that should be achieved to be a DevID is defined. The intent is that IDevIDs and LDevIDs are used with an open set of network protocols for authentication and such. In these protocols the DevID secret is used to sign a nonce or similar to proof the association of the DevID certificates with the device.

By contrast, EAT defines network protocol for proving trustworthiness to a Relying Party, the very thing that is not defined in [IEEE.802.1AR]. Nor does it give details on how keys, data and such are stored protected and accessed. EAT is intended to work with a variety of different on-device implementations ranging from minimal protection of assets to the highest levels of asset protection. It does not define any particular level of defense against attack, instead providing a set of security considerations.

EAT and DevID can be viewed as complimentary when used together or as competing to provide a device identity service.

C.1. DevID Used With EAT

As just described, EAT defines a network protocol and [IEEE.802.1AR] doesn’t. Vice versa, EAT doesn’t define an device implementation and DevID does.

Hence, EAT can be the network protocol that a DevID is used with. The DevID secret becomes the attestation key used to sign EATs. The DevID and its certificate chain become the Endorsement sent to the Verifier.

In this case the EAT and the DevID are likely to both provide a device identifier (e.g. a serial number). In the EAT it is the UEID (or SUEID). In the DevID (used as an endorsement), it is a device serial number included in the subject field of the DevID certificate. It is probably a good idea in this use for them to be the same serial number or for the UEID to be a hash of the DevID serial number.
C.2. How EAT Provides an Equivalent Secure Device Identity

The UEID, SUEID and other claims like OEM ID are equivalent to the secure device identity put into the subject field of a DevID certificate. These EAT claims can represent all the same fields and values that can be put in a DevID certificate subject. EAT explicitly and carefully defines a variety of useful claims.

EAT secures the conveyance of these claims by having them signed on the device by the attestation key when the EAT is generated. EAT also signs the nonce that gives freshness at this time. Since these claims are signed for every EAT generated, they can include things that vary over time like GPS location.

DevID secures the device identity fields by having them signed by the manufacturer of the device sign them into a certificate. That certificate is created once during the manufacturing of the device and never changes so the fields cannot change.

So in one case the signing of the identity happens on the device and the other in a manufacturing facility, but in both cases the signing of the nonce that proves the binding to the actual device happens on the device.

While EAT does not specify how the signing keys, signature process and storage of the identity values should be secured against attack, an EAT implementation may have equal defenses against attack. One reason EAT uses CBOR is because it is simple enough that a basic EAT implementation can be constructed entirely in hardware. This allows EAT to be implemented with the strongest defenses possible.

C.3. An X.509 Format EAT

It is possible to define a way to encode EAT claims in an X.509 certificate. For example, the EAT claims might be mapped to X.509 v3 extensions. It is even possible to stuff a whole CBOR-encoded unsigned EAT token into a X.509 certificate.

If that X.509 certificate is an IDevID or LDevID, this becomes another way to use EAT and DevID together.

Note that the DevID must still be used with an authentication protocol that has a nonce or equivalent. The EAT here is not being used as the protocol to interact with the rely party.
C.4. Device Identifier Permanence

In terms of permanence, an IDevID is similar to a UEID in that they do not change over the life of the device. They cease to exist only when the device is destroyed.

An SUEID is similar to an LDevID. They change on device life-cycle events.

[IEEE.802.1AR] describes much of this permanence as resistant to attacks that seek to change the ID. IDevID permanence can be described this way because [IEEE.802.1AR] is oriented around the definition of an implementation with a particular level of defense against attack.

EAT is not defined around a particular implementation and must work on a range of devices that have a range of defenses against attack. EAT thus can’t be defined permanence in terms of defense against attack. EAT’s definition of permanence is in terms of operations and device lifecycle.

Appendix D. CDDL for CWT and JWT

[RFC8392] was published before CDDL was available and thus is specified in prose, not CDDL. Following is CDDL specifying CWT as it is needed to complete this specification. This CDDL also covers the Claims-Set for JWT.

This however is NOT a normative or standard definition of CWT or JWT in CDDL. The prose in CWT and JWT remain the normative definition.
Claims-Set = {
  * $$Claims-Set-Claims
    * Claim-Label .feature "extended-claims-label" => any
}
Claim-Label = int / text
string-or-uri = text

$$Claims-Set-Claims //= ( iss-claim-label => string-or-uri )
$$Claims-Set-Claims //= ( sub-claim-label => string-or-uri )
$$Claims-Set-Claims //= ( aud-claim-label => string-or-uri )
$$Claims-Set-Claims //= ( exp-claim-label => time )
$$Claims-Set-Claims //= ( nbf-claim-label => time )
$$Claims-Set-Claims //= ( iat-claim-label => time )
$$Claims-Set-Claims //= ( cti-claim-label => bytes )

iss-claim-label = JC"iss", 1
sub-claim-label = JC"sub", 2
aud-claim-label = JC"aud", 3
exp-claim-label = JC"exp", 4
nbf-claim-label = JC"nbf", 5
iat-claim-label = JC"iat", 6
cti-claim-label = CBOR-ONLY<7> ; jti in JWT: different name and text

JSON-ONLY<J> = J .feature "json"
CBOR-ONLY<C> = C .feature "cbor"

; Be sure to have cddl 0.8.29 or higher for this to work
JC<J,C> = JSON-ONLY<J> / CBOR-ONLY<C>

; A JWT message is either a JWS or JWE in compact serialization form
; with the payload a Claims-Set. Compact serialization is the
; protected headers, payload and signature, each b64url encoded and
; separated by a ".". This CDDL simply matches top-level syntax of of
; a JWS or JWE since it is not possible to do more in CDDL.
JWT-Message = text .regexp "[A-Za-z0-9_=-]+.\.[A-Za-z0-9_=-]+.\.[A-Za-z0-9_=-]+"
CWT-Messages = CWT-Tagged-Message / CWT-Untagged-Message

; The payload of the COSE_Message is always a Claims-Set

; The contents of a CWT Tag must always be a COSE tag
CWT-Tagged-Message = #6.61(COSE_Tagged_Message)

; An untagged CWT may be a COSE tag or not
CWT-Untagged-Message = COSE_Messages

Appendix E. Changes from Previous Drafts

The following is a list of known changes from the previous drafts. This list is non-authoritative. It is meant to help reviewers see the significant differences.

E.1. From draft-rats-eat-01
  o Added UEID design rationale appendix

E.2. From draft-mandyam-rats-eat-00
  This is a fairly large change in the orientation of the document, but no new claims have been added.
  o Separate information and data model using CDDL.
  o Say an EAT is a CWT or JWT
  o Use a map to structure the boot_state and location claims

E.3. From draft-ietf-rats-eat-01
  o Clarifications and corrections for OEMID claim
  o Minor spelling and other fixes
  o Add the nonce claim, clarify jti claim

E.4. From draft-ietf-rats-eat-02
  o Roll all EUIs back into one UEID type
  o UEIDs can be one of three lengths, 128, 192 and 256.
o Added appendix justifying UEID design and size.

o Submods part now includes nested eat tokens so they can be named and there can be more than one of them

o Lots of fixes to the CDDL

o Added security considerations

E.5. From draft-ietf-rats-eat-03

o Split boot_state into secure-boot and debug-disable claims

o Debug disable is an enumerated type rather than Booleans

E.6. From draft-ietf-rats-eat-04

o Change IMEI-based UEIDs to be encoded as a 14-byte string

o CDDL cleaned up some more

o CDDL allows for JWTs and UCCSs

o CWT format submodules are byte string wrapped

o Allows for JWT nested in CWT and vice versa

o Allows UCCS (unsigned CWTs) and JWT unsecured tokens

o Clarify tag usage when nesting tokens

o Add section on key inclusion

o Add hardware version claims

o Collected CDDL is now filled in. Other CDDL corrections.

o Rename debug-disable to debug-status; clarify that it is not extensible

o Security level claim is not extensible

o Improve specification of location claim and added a location privacy section

o Add intended use claim
E.7. From draft-ietf-rats-eat-05
   o CDDL format issues resolved
   o Corrected reference to Location Privacy section

E.8. From draft-ietf-rats-eat-06
   o Added boot-seed claim
   o Rework CBOR interoperability section
   o Added profiles claim and section

E.9. From draft-ietf-rats-eat-07
   o Filled in IANA and other sections for possible preassignment of
     Claim Keys for well understood claims

E.10. From draft-ietf-rats-eat-08
   o Change profile claim to be either a URL or an OID rather than a
     test string

E.11. From draft-ietf-rats-eat-09
   o Add SUEIDs
   o Add appendix comparing IDevID to EAT
   o Added section on use for Evidence and Attestation Results
   o Fill in the key ID and endorsements identification section
   o Remove origination claim as it is replaced by key IDs and
     endorsements
   o Added manifests and software evidence claims
   o Add string labels non-claim labels for use with JSON (e.g. labels
     for members of location claim)
   o EAN-13 HW versions are no longer a separate claim. Now they are
     folded in as a CoSWID version scheme.
E.12. From draft-ietf-rats-eat-10

- Hardware version is made into an array of two rather than two claims.
- Corrections and wording improvements for security levels claim.
- Add swresults claim.
- Add dloas claim - Digital Letter of Approvals, a list of certifications.
- CDDL for each claim no longer in a separate sub section.
- Consistent use of terminology from RATS architecture document.
- Consistent use of terminology from CWT and JWT documents.
- Remove operating model and procedures; refer to CWT, JWT and RATS architecture instead.
- Some reorganization of Section 1.
- Moved a few references, including RATS Architecture, to informative.
- Add detached submodule digests and detached eat bundles (DEBs).
- New simpler and more universal scheme for identifying the encoding of a nested token.
- Made clear that CBOR and JSON are only mixed when nesting a token in another token.
- Clearly separate CDDL for JSON and CBOR-specific data items.
- Define UJCS (unsigned JWTs).
- Add CDDL for a general Claims-Set used by UCCS, UJCS, CWT, JWT and EAT.
- Top level CDDL for CWT correctly refers to COSE.
- OEM ID is specifically for HW, not for SW.
- HW OEM ID can now be a PEN.
- HW OEM ID can now be a 128-bit random number.
E.13. From draft-ietf-rats-eat-11

- Expand the examples section
- Add software and version claims as easy / JSON alternative to CoSWID

E.14. From draft-ietf-rats-eat-12

- Make use of the JC<> generic to express CDDL for both JSON and CBOR
- Reorganize claims into 4 sections, particularly claims about the entity and about the token
- Nonce wording - say nonce is required and other improvements
Clarify relationship of claims in evidence to results when forwarding

Clarify manufacturer switching UEID types

Add new section on the top-level token type that has CBOR-specific and JSON-specific CDDL since the top-level can’t be handled with JC<>

Remove definition of UCCS and UJCS, replacing it with a CDDL socket and mention of future token types

Split the examples into payload and top level tokens since UCCS can’t be used for examples any more (It was nice because you could see the payload claims in it easily, where you can’t with CWT)

DEB tag number is TBD rather than hard coded

Add appendix with non-normative CDDL for a Claims-Set, CWT and JWT

(Large reorganization of the document build and example verification makefile)

Use CoAP content format ID to distinguish manifest and evidence formats instead of CBOR tag

Added more examples, both CBOR and JSON

All CDDL is validating against all examples

Unassigned IANA requests are clearly TBD in the document (and have real values as is necessary in the example validation process)

Improve security-level claim

swresults claim is now measurement results claim

substantial redesign of measurement results claim

Abstract

This memo defines how to subscribe to YANG Event Streams for Remote Attestation Procedures (RATS). In RATS, Conceptional Messages, are defined. Analogously, the YANG module defined in this memo augments the YANG module for TPM-based Challenge-Response based Remote Attestation (CHARRA) to allow for subscription to remote attestation Evidence. Additionally, this memo provides the methods and means to define additional Event Streams for other Conceptual Message as illustrated in the RATS Architecture, e.g. Attestation Results, Endorsements, or Event Logs.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 8 September 2022.

1. Introduction

[I-D.ietf-rats-tpm-based-network-device-attest] and
[I-D.ietf-rats-yang-tpm-charra] define the operational prerequisites
and a YANG Model for the acquisition of Evidence and other
Conceptional Messages from a TPM-based network device. However,
there are limitations inherent in the challenge-response based
conceptual interaction model (CHARRA
[I-D.ietf-rats-reference-interaction-models]) upon which these
documents are based. One of these limitation is that it is up to a
Verifier to request signed Evidence as provided by
[I-D.ietf-rats-yang-tpm-charra], from a separate Attester which
contains a TPM. The result is that the interval between the
occurrence of a security-relevant change event, and the event’s
visibility within the interested RATS entity, such as a Verifier or a
Relying Party, can be unacceptably long. It is common to convey
Conceptual Messages ad-hoc or periodically via requests. As new
technologies emerge, some of these solutions require Conceptual
Messages to be conveyed from one RATS entity to another without the
need of continuous polling. Subscription to YANG Notifications
[RFC8639] provides a set of standardized tools to facilitate these
emerging requirements. This memo specifies a YANG augment to
subscribe to YANG modeled remote attestation Evidence as defined in
[I-D.ietf-rats-yang-tpm-charra]. Additionally, this memo provides
the means to define further Event Streams to convey Conceptual
Messages other than Evidence, such as Attestation Results,
Endorsements, or Event Logs.

In essence, the limitation of poll-based interactions results in two
adverse effects:

1. Conceptual Messages are not streamed to an interested consumer of
information, e.g., Verifiers or Relying Parties, as soon as they
are generated.

2. If they were to be streamed, Conceptual Messages are not
appraisable for their freshness in every scenario. This becomes
more important with Conceptual Messages that have a strong
dependency on freshness, such as Evidence and corresponding
Attestation Results.
This specification addresses the first adverse effect by enabling a consumer of Conceptual Messages (the subscriber) to request a continuous stream of new or updated Conceptual Messages via an [RFC8639] subscription to an <attestation> Event Stream. This new Event Stream is defined in this document and exists upon the producer of Conceptual Messages (the publisher). In the case of a Verifier’s subscription to an Attester’s Evidence, the Attester will continuously stream a requested set of freshly generated Evidence to the subscribing Verifier.

The second adverse effect results from the use of nonces in the challenge-response interaction model [I-D.ietf-rats-reference-interaction-models] realized in [I-D.ietf-rats-yang-tpm-charra]. In [I-D.ietf-rats-yang-tpm-charra], an Attester must wait for a new nonce from a Verifier before it generates a new TPM Quote. To address delays resulting from such a wait, this specification enables freshness to be asserted asynchronously via the streaming attestation interaction model [I-D.ietf-rats-reference-interaction-models]. To convey a RATS Conceptual Message, an initial nonce is provided during the subscription to an Event Stream.

There are several options to refresh a nonce provided by the initial subscription or its freshness characteristics. All of these methods are out-of-band of an established subscription to YANG Notifications. Two complementary methods are taken into account by this memo:

1. a central provider supplies new fresh nonces, e.g. via a Handle Provider that distributes Epoch IDs to all entities in a domain as described in [I-D.ietf-rats-architecture] and as facilitated by the Uni-Directional Remote Attestation described in [I-D.ietf-rats-reference-interaction-models] or

2. the freshness characteristics of a received nonce are updated by -- potentially periodic or ad-hoc -- out-of-band TPM Quote requests as facilitated by [I-D.ietf-rats-yang-tpm-charra].

Both approaches to update the freshness characteristics of the Conceptual Messages conveyed via subscription to YANG Notification that are taken into account by this memo assume that clock drift between involved entities can occur. In consequence, in some usage scenarios the timing considerations for freshness [I-D.ietf-rats-architecture] might have to be updated in some regular interval. Analogously, there are can be additional methods that are not describe by but nevertheless supported by this memo.
This memo enables to remove the two adverse effects described by using the YANG augment specified. The YANG augment supports, for example, a RATS Verifier to maintain a continuous appraisal procedure of verifiably fresh Attester Evidence without relying on continuous polling.

2. Terminology

The following terms are imported from [I-D.ietf-rats-architecture]: Attester, Conceptual Message, Evidence, Relying Party, and Verifier. Also imported are the time definitions time(VG), time(NS), time(EG), time(RG), and time(RA) from that document’s Appendix A. The following terms are imported from [RFC8639]: Event Stream, Subscription, Event Stream Filter, Dynamic Subscription.

2.1. Requirements Notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 RFC2119 [RFC8174] when, and only when, they appear in all capitals, as shown here.

3. Operational Model

[I-D.ietf-rats-tpm-based-network-device-attest] describes the conveyance of TPM-based Evidence from a Verifier to an Attester using the CHARRA interaction model [I-D.ietf-rats-reference-interaction-models]. The operational model and corresponding sequence diagram described in this section is based on [I-D.ietf-rats-yang-tpm-charra]. The basis for interoperability required for additional types of Event Streams is covered in Section 6. The following sub-section focuses on subscription to YANG Notifications to the <attestation> Event Stream.

3.1. Sequence Diagram

Figure 1 below is a sequence diagram which updates Figure 5 of [I-D.ietf-rats-tpm-based-network-device-attest]. This sequence diagram replaces the [I-D.ietf-rats-tpm-based-network-device-attest] TPM-specific challenge-response interaction model with a [RFC8639] Dynamic Subscription to an <attestation> Event Stream. The contents of the <attestation> Event Stream are defined below within Section 4.
Figure 1: YANG Subscription Model for Remote Attestation

* time(VG,RG,RA) are identical to the corresponding time definitions from [I-D.ietf-rats-tpm-based-network-device-attest].

* time(VG’,RG’,RA’) are subsequent instances of the corresponding times from Figure 5 in [I-D.ietf-rats-tpm-based-network-device-attest].
* time(NS) - the subscriber generates a nonce and makes an [RFC8639] <establish-subscription> request based on a nonce. This request also includes the augmentations defined in this document’s YANG model. Key subscription RPC parameters include:

- the nonce,

- a set of PCRs of interest which the wants to appraise, and

- an optional filter which can reduce the logged events on the <attestation> stream pushed to the Verifier.

* time(EG) - an initial response of Evidence is returned to the Verifier. This includes:

- a replay of filtered log entries which have extended into a PCR of interest since boot are sent in the <pcr-extend> notification, and

- a signed TPM quote that contains at least the PCRs from the <establish-subscription> RPC are included in a <tpm12-attestation> or <tpm20-attestation>). This quote must have included the nonce provided at time(NS).

* time(VG’,EG’) - this occurs when a PCR is extended subsequent to time(EG). Immediately after the extension, the following information needs to be pushed to the Verifier:

- any values extended into a PCR of interest,

- a signed TPM Quote showing the result the PCR extension, and

- and a handle (see Section 6. in [I-D.ietf-rats-reference-interaction-models], which is either the initially received nonce or a more recently received Epoch ID (see Section 10.3. in [I-D.ietf-rats-architecture] that contains a new nonce or equivalent qualified data.

One way to acquire a new time synchronisation that allows for the reuse of the initially received nonce as a fresh handle is elaborated on in the follow section Section 3.2.

3.2. Continuously Verifying Freshness

As there is no new Verifier nonce provided at time(EG’), it is important to validate the freshness of TPM Quotes which are delivered at that time. The method of doing this verification will vary based on the capabilities of the TPM cryptoprocessor used.
3.2.1. TPM 1.2 Quote

The [RFC8639] notification format includes the <eventTime> object. This can be used to determine the amount of time subsequent to the initial subscription each notification was sent. However this time is not part of the signed results which are returned from the Quote, and therefore is not trustworthy as objects returned in the Quote. Therefore a Verifier MUST periodically issue a new nonce, and receive this nonce within a TPM quote response in order to ensure the freshness of the results. This can be done using the <tpml2-challenge-response-attestation> RPC from [I-D.ietf-rats-yang-tpm-charra].

3.2.2. TPM 2 Quote

When the Attester includes a TPM2 compliant cryptoprocessor, internal time-related counters are included within the signed TPM Quote. By including a initial nonce in the [RFC8639] subscription request, fresh values for these counters are pushed as part of the first TPM Quote returned to the Verifier. And then as shown by [I-D.birkholz-rats-tuda], subsequent TPM Quotes delivered to the Verifier can be appraised for freshness based on the predictable incrementing of these time-related counters.

The relevant internal time-related counters defined within [TPM2.0] can be seen within <tpms-clock-info>. These counters include the <clock>, <reset-counter>, and <restart-counter> objects. The rules for appraising these objects are as follows:

* If the <clock> has incremented for no more than the same duration as both the <eventTime> and the Verifier’s internal time since the initial time(EG) and any previous time(EG’), then the TPM Quote may be considered fresh. Note that [TPM2.0] allows for +/- 15% clock drift. However many chips significantly improve on this maximum drift. If available, chip specific maximum drifts SHOULD be considered during the appraisal process.

* If the <reset-counter>, <restart-counter> has incremented. The existing subscription MUST be terminated, and a new <establish-subscription> SHOULD be generated.

* If a TPM Quote on any subscribed PCR has not been pushed to the Verifier for a duration of an Attester defined heartbeat interval, then a new TPM Quote notification should be sent to the Verifier. This may often be the case, as certain PCRs might be infrequently updated.
4. Remote Attestation Event Stream

The <attestation> Event Stream is an [RFC8639] compliant Event Stream which is defined within this section and within the YANG Module of [I-D.ietf-rats-yang-tpm-charra]. This Event Stream contains YANG notifications which carry Evidence to assist a Verifier in appraising the Trustworthiness Level of an Attester. Data Nodes within Section 4.6 allow the configuration of this Event Stream’s contents on an Attester.

This <attestation> Event Stream may only be exposed on Attesters supporting [I-D.ietf-rats-tpm-based-network-device-attest]. As with [I-D.ietf-rats-tpm-based-network-device-attest], it is up to the Verifier to understand which types of cryptoprocessors and keys are acceptable.

4.1. Subscription to the <attestation> Event Stream

To establish a subscription to an Attester in a way which provides provably fresh Evidence, initial randomness must be provided to the Attester. This is done via the augmentation of a <nonce-value> into [RFC8639] the <establish-subscription> RPC. Additionally, a Verifier must ask for PCRs of interest from a platform.

    augment /sn:establish-subscription/sn:input:
      +---w nonce-value    binary
      +---w pcr-index*    tpm:pcr

The result of the subscription will be that passing of the following information:

1. <tpm12-attestation> and <tpm20-attestation> notifications which include the provided <nonce-value>. These attestation notifications MUST at least include all the <pcr-indicies> requested in the RPC.
2. a series of `<pcr-extend>` notifications which reference the
requested PCRs on all TPM based cryptoprocessors on the Attester.

3. `<tpm12-attestation>` and `<tpm20-attestation>` notifications
generated within a few seconds of the `<pcr-extend>` notifications.
These attestation notifications MUST at least include any PCRs
extended.

If the Verifier does not want to see the logged extend operations for
all PCRs available from an Attester, an Event Stream Filter should be
applied. This filter will remove Evidence from any PCRs which are
not interesting to the Verifier.

4.2. Replaying a history of previous TPM extend operations

Unless it is relying on Known Good Values, a Verifier will need to
acquire a history of PCR extensions since the Attester has been
booted. This history may be requested from the Attester as part of
the `<establish-subscription>` RPC. This request is accomplished by
placing a very old `<replay-start-time>` within the original RPC
request. As the very old `<replay-start-time>` will pre-date the time
of Attester boot, a `<replay-start-time-revision>` will be returned in
the `<establish-subscription>` RPC response, indicating when the
Attester booted. Immediately following the response (and before the
notifications above) one or more `<pcr-extend>` notifications which
document all extend operations which have occurred for the requested
PCRs since boot will be sent. Many extend operations to a single PCR
index on a single TPM SHOULD be included within a single
notification.

Note that if a Verifier has a partial history of extensions, the
`<replay-start-time>` can be adjusted so that known extensions are not
forwarded.

The end of this history replay will be indicated with the [RFC8639]
`<replay-completed>` notification. For more on this sequence, see
Section 2.4.2.1 of [RFC8639].

After the `<replay-complete>` notification is provided, a TPM Quote
will be requested and the result passed to the Verifier via a
`<tpm12-attestation>` and `<tpm20-attestation>` notification. If there
have been any additional extend operations which have changed a
subscribed PCR value in this quote, these MUST be pushed to the
Verifier before the `<tpm12-attestation>` and `<tpm20-attestation>
notification.
At this point the Verifier has sufficient Evidence appraise the reported extend operations for each PCR, as well compare the expected value of the PCR value against that signed by the TPM.

4.2.1. TPM2 Heartbeat

For TPM2, make sure that every requested PCR is sent within an `<tpm20-attestation>` no less frequently than once per heartbeat interval. This MAY be done with a single `<tpm20-attestation>` notification that includes all requested PCRs every heartbeat interval. This MAY be done with several `<tpm20-attestation>` notifications at different times during that heartbeat interval.

4.3. YANG notifications placed on the `<attestation>` Event Stream

4.3.1. pcr-extend

This notification documents when a subscribed PCR is extended within a single TPM cryptoprocessor. It SHOULD be emmitted no less than the `<marshalling-period>` after an the PCR is first extended. (The reason for the marshalling is that it is quite possible that multiple extensions to the same PCR have been made in quick succession, and these should be reflected in the same notification.) This notification MUST be emmitted prior to a `<tpm12-attestation>` or `<tpm20-attestation>` notification which has included and signed the results of any specific PCR extension. If pcr extending events occur during the generation of the `<tpm12-attestation>` or `<tpm20-attestation>` notification, the marshalling period MUST be extended so that a new `<pcr-extend>` is not sent until the corresponding notifications have been sent.

              +---ro filedata-hash-algorithm? string
              +---ro template-hash-algorithm? string
              +---ro template-hash?       binary
              +---ro pcr-index?           pcr
              +---ro signature?          binary
Each `<pcr-extend>` MUST include one or more values being extended into
the PCR. These are passed within the `<extended-with>` object. For
each extension, details of the event SHOULD be provided within the
`<event-details>` object. The format of any included `<event-details>`
is identified by the `<event-type>`.

This document includes two YANG structures which may be inserted into the `<event-details>`.
These two structures are: `<ima-event-log>` and `<bios-event-log>`.
Implementations wanting to provide additional documentation of a type
of PCR extension may choose to define additional YANG structures
which can be placed into `<event-details>`.

### 4.3.2. tpm12-attestation

This notification contains an instance of a TPM1.2 style signed
cryptoprocessor measurement. It is supplemented by Attester
information which is not signed. This notification is generated and
emitted from an Attester when at least one PCR identified within the
subscribed `<pcr-indices>` has changed from the previous
`<tpm12-attestation>` notification. This notification MUST NOT include
the results of any PCR extensions not previously reported by a `<pcr-
extend>`.

This notification SHOULD be emitted as soon as a TPM Quote
can extract the latest PCR hashed values. This notification MUST be
emitted prior to a subsequent `<pcr-extend>`.

```
+---n tpm12-attestation {taa:TPM12}?
  +---ro certificate-name       tpm:certificate-name-ref
  +---ro up-time?               uint32
  +---ro TPM_QUOTE2?            binary
  +---ro TPM12-hash-algo?       identityref
  +---ro unsigned-pcr-values* 
  +---ro pcr-index* tpm:pcr
  +---ro pcr-value* binary
```

All YANG objects above are defined within
[I-D.ietf-rats-yang-tpm-charra]. The `<tpm12-attestation>` is not
replayable.

### 4.3.3. tpm20-attestation

This notification contains an instance of TPM2 style signed
cryptoprocessor measurements. It is supplemented by Attester
information which is not signed. This notification is generated at
two points in time:

* every time at least one PCR has changed from a previous
  tpm20-attestation. In this case, the notification SHOULD be
  emitted within 10 seconds of the corresponding `<pcr-extend>` being
  sent:
* after a locally configurable minimum heartbeat period since a previous tpm20-attestation was sent.

```yaml
---n tpm20-attestation {taa:TPM20}?
  +---ro certificate-name tpm:certificate-name-ref
  +---ro TPMS_QUOTE_INFO binary
  +---ro quote-signature? binary
  +---ro up-time? uint32
  +---ro unsigned-pcr-values* []
    +---ro TPM20-hash-algo? identityref
    +---ro pcr-values* [pcr-index]
      +---ro pcr-index pcr
      +---ro pcr-value? binary
```

All YANG objects above are defined within [I-D.ietf-rats-yang-tpm-charra]. The <tpm20-attestation> is not replayable.

4.4. Filtering Evidence at the Attester

It can be useful _not_ to receive all Evidence related to a PCR. An example of this is when a Verifier maintains known good values of a PCR. In this case, it is not necessary to send each extend operation.

To accomplish this reduction, when an RFC8639 <establish-subscription> RPC is sent, a <stream-filter> as per RFC8639, Section 2.2 can be set to discard a <pcr-extend> notification when the <pcr-index-changed> is uninteresting to the verifier.

4.5. Replaying previous PCR Extend events

To verify the value of a PCR, a Verifier must either know that the value is a known good value [KGV] or be able to reconstruct the hash value by viewing all the PCR-Extends since the Attester rebooted. Wherever a hash reconstruction might be needed, the <attestation> Event Stream MUST support the RFC8639 <replay> feature. Through the <replay> feature, it is possible for a Verifier to retrieve and sequentially hash all of the PCR extending events since an Attester booted. And thus, the Verifier has access to all the evidence needed to verify a PCR’s current value.
4.6. Configuring the <attestation> Event Stream

Figure 2 is a tree diagram which exposes the operator configurable elements of the <attestation> Event Stream. This allows an Attester to select what information should be available on the stream. A fetch operation also allows an external device such as a Verifier to understand the current configuration of stream.

Almost all YANG objects below are defined via reference from [I-D.ietf-rats-yang-tpm-charra]. There is one object which is new with this model however. <tpm2-heartbeat> defines the maximum amount of time which should pass before a subscriber to the Event Stream should get a <tpm20-attestation> notification from devices which contain a TPM2.

```
augment /tpm:rats-support-structures:
  +--rw tras:marshalling-period?  uint8
  +--rw tras:tpm12-subscribed-signature-scheme?
      |   -> ../tpm:attester-supported-algos/tpm12-asymmetric-signing
      |      {taa:TPM12}?
  +--rw tras:tpm20-subscribed-signature-scheme?
      |   -> ../tpm:attester-supported-algos/tpm20-asymmetric-signing
      |      {taa:TPM20}?
  +--rw tras:tpm20-subscription-heartbeat?  uint16
      {taa:TPM20}?

augment /tpm:rats-support-structures/tpm:tpms:
  +--rw tras:subscription-aik?        tpm:certificate-name-ref
  +--rw (tras:subscribable)?
      +--:(tras:tpm12-stream) {taa:tpm12}?
      |   +--rw tras:tpm12-hash-algo?   identityref
      |   +--rw tras:tpm12-pcr-index*   tpm:pcr
      +--:(tras:tpm20-stream) {taa:tpm20}?
      |   +--rw tras:tpm20-hash-algo?   identityref
      |   +--rw tras:tpm20-pcr-index*   tpm:pcr
```

<CODE ENDS>

6. Event Streams for Conceptual Messages

Analogous to the [RFC8639] compliant <attestation> Event Stream for the conveyance of remote attestation Evidence as defined in Section Section 4, additional Event Streams can be defined for this YANG augment. Additional Event Streams require separate YANG augment specifications that provide the Event Stream definition and optionally a content format definition either via subscriptions to YANG datastores or dedicated YANG Notifications. It is possible to use either YANG subscription methods to other YANG modules for RATS Conceptual Messages or to define Event Streams for other none-YANG-modeled data. In the context of RATS Conceptual Messages, both options MUST be a specified via YANG augments to this specification.

7. Security Considerations

To be written.

8. IANA Considerations

Abstract

This document describes interaction models for remote attestation procedures (RATS). Three conveying mechanisms -- Challenge/Response, Uni-Directional, and Streaming Remote Attestation -- are illustrated and defined. Analogously, a general overview about the information elements typically used by corresponding conveyance protocols are highlighted.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 30 July 2022.

1. Introduction

Remote ATtestation procedures (RATS, [I-D.ietf-rats-architecture]) are workflows composed of roles and interactions, in which Verifiers create Attestation Results about the trustworthiness of an Attester’s system component characteristics. The Verifier’s assessment in the form of Attestation Results is created based on Attestation Policies and Evidence -- trustable and tamper-evident Claims Sets about an Attester’s system component characteristics -- generated by an Attester. The roles _Attester_ and _Verifier_, as well as the Conceptual Messages _Evidence_ and _Attestation Results_ are concepts defined by the RATS Architecture [I-D.ietf-rats-architecture]. This document defines interaction models that can be used in specific RATS-related solution documents. The primary focus of this document is the conveyance of attestation Evidence. The reference models defined can also be applied to the conveyance of other Conceptual Messages in RATS. Specific goals of this document are to:

1.) prevent inconsistencies in descriptions of interaction models in other documents (due to text cloning and evolution over time), and to
2.) enable to highlight an exact delta/divergence between the core set of characteristics captured here in this document and variants of these interaction models used in other specifications or solutions.

In summary, this document enables the specification and design of trustworthy and privacy preserving conveyance methods for attestation Evidence from an Attester to a Verifier. While the conveyance of other Conceptual Messages is out-of-scope the methods described can also be applied to the conveyance of, for example, Endorsements or Attestation Results.

2. Terminology

This document uses the following set of terms, roles, and concepts as defined in [I-D.ietf-rats-architecture]: Attester, Verifier, Relying Party, Conceptual Message, Evidence, Endorsement, Attestation Result, Appraisal Policy, Attesting Environment, Target Environment.

A PKIX Certificate is an X.509v3 format certificate as specified by [RFC5280].

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.
2.1. Disambiguation

The term "Remote Attestation" is a common expression and often associated or connoted with certain properties. The term "Remote" in this context does not necessarily refer to a remote entity in the scope of network topologies or the Internet. It rather refers to decoupled systems or entities that exchange the payload of the Conceptual Message type called Evidence [I-D.ietf-rats-architecture]. This conveyance can also be "Local", if the Verifier role is part of the same entity as the Attester role, e.g., separate system components of the same Composite Device (a single RATS entity). Even if an entity takes on two or more different roles, the functions they provide typically reside in isolated environments that are components of the same entity. Examples of such isolated environments include: a Trusted Execution Environment (TEE), Baseboard Management Controllers (BMCs), as well as other physical or logical protected/isolated/shielded Computing Environments (e.g. embedded Secure Elements (eSE) or Trusted Platform Modules (TPM)). Readers of this document should be familiar with the concept of Layered Attestation as described in Section 3.1 Two Types of Environments of an Attester in [I-D.ietf-rats-architecture] and the definition of Attestation as described in [I-D.ietf-rats-tpm-based-network-device-attest].

3. Scope and Intent

This document focuses on generic interaction models between Attesters and Verifiers in order to convey Evidence. Complementary procedures, functions, or services that are required for a complete semantic binding of the concepts defined in [I-D.ietf-rats-architecture] are out-of-scope of this document. Examples include: identity establishment, key distribution and enrollment, time synchronization, as well as certificate revocation.

Furthermore, any processes and duties that go beyond carrying out remote attestation procedures are out-of-scope.

For instance, using the results of a remote attestation procedure that are created by the Verifier, e.g., how to triggering remediation actions or recovery processes, as well as such remediation actions and recovery processes themselves, are also out-of-scope.
The interaction models illustrated in this document are intended to provide a stable basis and reference for other solutions documents inside or outside the IETF. Solution documents of any kind can reference the interaction models in order to avoid text clones and to avoid the danger of subtle discrepancies. Analogously, deviations from the generic model descriptions in this document can be illustrated in solutions documents to highlight distinct contributions.

4. Essential Requirements

In order to ensure appropriate conveyance of Evidence, there exist essential requirements which MUST be fulfilled:

Integrity: Information provided by an Attester MUST be integral. This may be achieved by means of a digital signature over Attestation Evidence. The signature may be symmetric, such as an HMAC, or asymmetric, such as ECDSA.

Authentication: The information provided by the Attester MUST be authentic. For that purpose, the Attester should authenticate itself to the Verifier. This may be an implicit authentication by means of a digital signature over the Attestation Evidence, which does not require additional protocol steps, or may be achieved by using a confidential channel by means of encryption.

4.1. Endorsement of Attesting Environments

Via its Attesting Environments, an Attester only generates Evidence about its Target Environments. After being appraised to be trustworthy, a Target Environment may become a new Attesting Environment in charge of generating Evidence for further Target Environments. [I-D.ietf-rats-architecture] explains this as Layered Attestation. Layered Attestation has to start with an initial Attesting Environment. In essence, there cannot be turtles all the way down [turtles]. At this rock bottom of Layered Attestation, the Attesting Environments are always called Roots of Trust (RoT). An Attester cannot generate Evidence about its own RoTs by design. As a consequence, a Verifier requires trustable statements about this subset of Attesting Environments from a different source than the Attester itself. The corresponding trustable statements are called Endorsements and originate from external, trustable entities that take on the role of an Endorser (e.g., supply chain entities).
5. Normative Prerequisites

In order to ensure an appropriate conveyance of Evidence via interaction models in general, the following set of prerequisites MUST be in place to support the implementation of interaction models:

Authentication Secret: An Authentication Secret MUST be available exclusively to an Attesting Environment of an Attester.

The Attester MUST protect Claims with that Authentication Secret, thereby proving the authenticity of the Claims included in Evidence. The Authentication Secret MUST be established before RATS can take place.

Attester Identity: A statement about a distinguishable Attester made by an Endorser.

The provenance of Evidence with respect to a distinguishable Attesting Environment MUST be correct and unambiguous.

An Attester Identity MAY be an Authentication Secret which is available exclusively to one of the Attesting Environments of an Attester. It MAY be a unique identity, MAY be included in a zero-knowledge proof (ZKP), MAY be part of a group signature, or it MAY be a randomized DAA credential [DAA].

Attestation Evidence Authenticity: Attestation Evidence MUST be authentic.

In order to provide proofs of authenticity, Attestation Evidence SHOULD be cryptographically associated with an identity document (e.g., a PKIX certificate or trusted key material, or a randomized DAA credential [DAA]), or SHOULD include a correct, unambiguous and stable reference to an accessible identity document.

Evidence Freshness: Evidence MUST include an indicator about its freshness that can be understood by a Verifier. Analogously, interaction models MUST support the conveyance of proofs of freshness in a way that is useful to Verifiers and their appraisal procedures.

Evidence Protection: Evidence MUST be a set of well-formatted and well-protected Claims that an Attester can create and convey to a Verifier in a tamper-evident manner.
6. Generic Information Elements

This section defines the information elements that are vital to all kinds interaction models. Varying from solution to solution, generic information elements can be either included in the scope of protocol messages (instantiating Conceptual Messages) or can be included in additional protocol parameters or payload. Ultimately, the following information elements are required by any kind of scalable remote attestation procedure using one or more of the interaction models provided.

Authentication Secret IDs (`authSecIDs`): _mandatory_

A statement representing an identifier list that MUST be associated with corresponding Authentication Secrets used to protect Claims included in Evidence.

Each distinguishable Attesting Environment has access to a protected capability that provides an Authentication Secret associated with that Attesting Environment. Consequently, an Authentication Secret ID can also identify an Attesting Environment.

Handle (`handle`): _mandatory_

A statement that is intended to uniquely distinguish received Evidence and/or determine the freshness of Evidence.

A Verifier can also use a Handle as an indicator for authenticity or attestation provenance, as only Attesters and Verifiers that are intended to exchange Evidence should have knowledge of the corresponding Handles. Examples include Nonces or signed timestamps.

Claims (`claims`): _mandatory_

Claims are assertions that represent characteristics of an Attester’s Target Environment.

Claims are part of a Conceptual Message and are, for example, used to appraise the integrity of Attesters via Verifiers. The other information elements in this section can be expressed as Claims in any type of Conceptual Messages.

Event Logs (`eventLogs`): _optional_

Event Logs accompany Claims by providing event trails of security-
critical events in a system. The primary purpose of Event Logs is to support Claim reproducibility by providing information on how Claims originated.

Reference Values (‘refValues’) _mandatory_

Reference Values as defined in [I-D.ietf-rats-architecture]. This specific type of Claims is used to appraise Claims incorporated in Evidence. For example, Reference Values MAY be Reference Integrity Measurements (RIM) or assertions that are implicitly trusted because they are signed by a trusted authority (see Endorsements in [I-D.ietf-rats-architecture]). Reference Values typically represent (trusted) Claim sets about an Attester’s intended platform operational state.

Claim Selection (‘claimSelection’): _optional_

A (sub-)set of Claims which can be created by an Attester.

Claim Selections act as filters to specify the exact set of Claims to be included in Evidence. In a remote attestation process, a Verifier sends a Claim Selection, among other elements, to an Attester. An Attester MAY decide whether or not to provide all requested Claims from a Claim Selection to the Verifier.

Collected Claims (‘collectedClaims’): _mandatory_

Collected Claims represent a (sub-)set of Claims created by an Attester.

Collected Claims are gathered based on the Claims selected in the Claim Selection. If a Verifier does not provide a Claim Selection, then all available Claims on the Attester are part of the Collected Claims.

Evidence (‘evidence’): _mandatory_

A set of Claims that consists of a list of Authentication Secret IDs that each identifies an Authentication Secret in a single Attesting Environment, the Attester Identity, Claims, and a Handle. Attestation Evidence MUST cryptographically bind all of these information elements. Evidence MUST be protected via an Authentication Secret. The Authentication Secret MUST be trusted by the Verifier as authoritative.

Attestation Result (‘attestationResult’): _mandatory_

An Attestation Result is produced by the Verifier as the output of
the appraisal of Evidence. Attestation Results include condensed assertions about integrity or other characteristics of the corresponding Attester that are processible by Relying Parties.

7. Interaction Models

The following subsections introduce and illustrate the interaction models:

1. Challenge/Response Remote Attestation
2. Uni-Directional Remote Attestation
3. Streaming Remote Attestation

Each section starts with a sequence diagram illustrating the interactions between Attester and Verifier. While the presented interaction models focus on the conveyance of Evidence, the intention of this document is in support of future work that applies the presented models to the conveyance of other Conceptual Messages, namely Attestation Results, Endorsements, Reference Values, or Appraisal Policies.

All interaction models have a strong focus on the use of a handle to incorporate a type of proof of freshness and to prevent replay attacks. The way these handles are processed is the most prominent difference between the three interaction models.

7.1. Challenge/Response Remote Attestation
The Attester boots up and thereby produces claims about its boot state and its operational state. Event Logs accompany the produced claims by providing an event trail of security-critical events in a system. Claims are produced by all attesting Environments of an Attester system.

The Challenge/Response remote attestation procedure is initiated by the Verifier by sending a remote attestation request to the Attester. A request includes a Handle, a list of Authentication Secret IDs, and a Claim Selection.

In the Challenge/Response model, the handle is composed of qualifying data in the form of a practically infeasible to guess nonce, such as a cryptographically strong random number. The Verifier-generated nonce is intended to guarantee Evidence freshness and to prevent replay attacks.

The list of Authentication Secret IDs selects the attestation keys with which the Attester is requested to sign the Attestation Evidence. Each selected key is uniquely associated with an Attesting Environment of the Attester. As a result, a single Authentication Secret ID identifies a single Attesting Environment. Correspondingly, a particular set of Evidence originating from a particular Attesting Environment in a composite device can be requested via multiple Authentication Secret IDs. Methods to acquire Authentication Secret IDs or mappings between Attesting Environments to Authentication Secret IDs are out-of-scope of this document.
The Attester collects Claims based on the Claim Selection. With the Claim Selection the Verifier defines the set of Claims it requires. Correspondingly, collected Claims can be a subset of the produced Claims. This could be all available Claims, depending on the Claim Selection. If the Claim Selection is omitted, then by default all Claims that are known and available on the Attester MUST be used to create corresponding Evidence. For example, when performing a boot integrity evaluation, a Verifier may only be requesting a particular subset of claims about the Attester, such as Evidence about BIOS/UEFI and firmware that the Attester booted up, and not include information about all currently running software.

With the Handle, the Authentication Secret IDs, and the collected Claims, the Attester produces signed Evidence. That is, it digitally signs the Handle and the collected Claims with a cryptographic secret identified by the Authentication Secret ID. This is done once per Attesting Environment which is identified by the particular Authentication Secret ID. The Attester communicates the signed Evidence as well as all accompanying Event Logs back to the Verifier.

While it is crucial that Claims, the Handle, and the Attester Identity information (i.e., the Authentication Secret) MUST be cryptographically bound to the signature of Evidence, they MAY be presented obfuscated, encrypted, or cryptographically blinded. For further reference see section Section 10.

As soon as the Verifier receives the Evidence and the Event Logs, it appraises the Evidence. For this purpose, it validates the signature, the Attester Identity, and the Handle, and then appraises the Claims. Appraisal procedures are application-specific and can be conducted via comparison of the Claims with corresponding Reference Values, such as Reference Integrity Measurements. The final output of the Verifier are Attestation Results. Attestation Results constitute new Claim Sets about the properties and characteristics of an Attester, which enables Relying Parties, for example, to assess an Attester’s trustworthiness.

7.1.1. Models and example sequences of Challenge/Response Remote Attestation

According to the RATS Architecture, two reference models for Challenge/Response Attestation have been proposed. This section highlights the information flows between the Attester, Verifier and Relying Party undergoing Remote Attestation Procedure, using these models.

1. Passport Model
The passport model is so named because of its resemblance to how nations issue passports to their citizens. In this model, the attestation sequence is a two step procedure. In the first step, an Attester conveys Evidence to a Verifier which compares the Evidence against its appraisal policy. The Verifier then gives back an Attestation Result to the Attester, which simply caches it. In the second step, the Attester presents the Attestation Result (and possibly additional Claims/evidence) to a Relying Party, which then compares this information against its own appraisal policy to establish the trustworthiness of the Attester.

```
| Attester | R. P. | Verifier |

generateClaims(attestingEnvironment) => claims, eventLogs

requestAttestation(handle, authSecIDs, claimSelection) => collectedClaims

generateEvidence(handle, authSecIDs, collectedClaims) => evidence

evidence, eventLogs --> appraiseEvidence(evidence, eventLogs, refValues)
attestationResults <- attestationResults(evidence, results)
```
1. BackGround Check Model

The background-check model is so named because of the resemblance of how employers and volunteer organizations perform background checks. In this model, the attestation sequence is initiated by a Relying Party. The Attester conveys Evidence to the Relying Party, which does not process its payload, but realys the message and optionally check its signature against a policed trust anchor store. Upon receiving the evidence the Relying Party initiates a session with the Verifier. Once session is established, it forwards the received Evidence to the Verifier. The Verifier, appraises the received Evidence according to its appraisal policy for Evidence and returns a
corresponding Attestation Result to the Relying Party. The Relying Party then checks the Attestation Result against its own appraisal policy to conclude attestation.

```
<table>
<thead>
<tr>
<th>Attester</th>
<th>Verifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>R. P.</td>
<td>----------</td>
</tr>
</tbody>
</table>
```

```
| generateClaims(attestingEnvironment) => claims, eventLogs |
| requestAttestation(handle, authSecIDs, claimSelection) |
| collectClaims(claims, claimSelection) => collectedClaims |
| generateEvidence(handle, authSecIDs, collectedClaims) => evidence |
| evidence, eventLogs ------------------------------------> |
| appraiseEvidence() |
| results <--------------- |
| appraiseResults(evidence, results) |
```

7.2. Uni-Directional Remote Attestation
Uni-Directional Remote Attestation procedures can be initiated both by the Attester and by the Verifier. Initiation by the Attester can result in unsolicited pushes of Evidence to the Verifier. Initiation by the Verifier always results in solicited pushes to the Verifier.
The Uni-Directional model uses the same information elements as the Challenge/Response model. In the sequence diagram above, the Attester initiates the conveyance of Evidence (comparable with a RESTful POST operation or the emission of a beacon). While a request of Evidence from the Verifier would result in a sequence diagram more similar to the Challenge/Response model (comparable with a RESTful GET operation). The specific manner how Handles are created and used always remains as the distinguishing quality of this model.

In the Uni-Directional model, handles are composed of cryptographically signed trusted timestamps as shown in [I-D.birkholz-rats-tuda], potentially including other qualifying data. The Handles are created by an external 3rd entity -- the Handle Distributor -- which includes a trustworthy source of time, and takes on the role of a Time Stamping Authority (TSA, as initially defined in [RFC3161]). Timestamps created from local clocks (absolute clocks using a global timescale, as well as relative clocks, such as tick-counters) of Attesters and Verifiers MUST be cryptographically bound to fresh Handles received from the Handle Distributor. This binding provides a proof of synchronization that MUST be included in all produced Evidence. Correspondingly, conveyed Evidence in this model provides a proof that it was fresh at a certain point in time.

While periodically pushing Evidence to the Verifier, the Attester only needs to generate and convey evidence generated from Claim values that have changed and new Event Logs entries since the previous conveyance. These updates reflecting the differences are called "delta" in the sequence diagram above.

Effectively, the Uni-Directional model allows for a series of Evidence to be pushed to multiple Verifiers simultaneously. Methods to detect excessive time drift that would mandate a fresh Handle to be received by the Handle Distributor as well as timing of Handle distribution are out-of-scope of this document.

### 7.3. Streaming Remote Attestation
Streaming Remote Attestation procedures require the setup of subscription state. Setting up subscription state between a Verifier and an Attester is conducted via a subscribe operation. The subscribe operation is used to convey required Handles for producing Evidence. Effectively, this allows for a series of Evidence to be pushed to a Verifier, similar to the Uni-Directional model. While a Handle Distributor is not required in this model, it is also limited
to bi-lateral subscription relationships in which each Verifier has to create and provide its individual Handle. Handles provided by a specific subscribing Verifier MUST be used in Evidence generation for that specific Verifier. The Streaming model uses the same information elements as the Challenge/Response and the Uni-Directional model. Methods to detect excessive time drift that would mandate a refreshed Handle to be conveyed via another subscribe operation are out-of-scope of this document.

8. Additional Application-Specific Requirements

Depending on the use cases covered, there can be additional requirements. An exemplary subset is illustrated in this section.

8.1. Confidentiality

Confidentiality of exchanged attestation information may be desirable. This requirement usually is present when communication takes place over insecure channels, such as the public Internet. In such cases, TLS may be used as a suitable communication protocol which provides confidentiality protection. In private networks, such as carrier management networks, it must be evaluated whether or not the transport medium is considered confidential.

8.2. Mutual Authentication

In particular use cases, mutual authentication may be desirable in such a way that a Verifier also needs to prove its identity to the Attester, instead of only the Attester proving its identity to the Verifier.

8.3. Hardware-Enforcement/Support

Depending on given usage scenarios, hardware support for secure storage of cryptographic keys, crypto accelerators, as well as protected or isolated execution environments can be mandatory requirements. Well-known technologies in support of these requirements are roots of trusts, such as Hardware Security Modules (HSM), Physically Unclonable Functions (PUFs), Shielded Secrets, or Trusted Executions Environments (TEEs).

9. Implementation Status

Note to RFC Editor: Please remove this section as well as references to [BCP205] before AUTH48.
This section records the status of known implementations of the protocol defined by this specification at the time of posting of this Internet-Draft, and is based on a proposal described in [BCP205]. The description of implementations in this section is intended to assist the IETF in its decision processes in progressing drafts to RFCs. Please note that the listing of any individual implementation here does not imply endorsement by the IETF. Furthermore, no effort has been spent to verify the information presented here that was supplied by IETF contributors. This is not intended as, and must not be construed to be, a catalog of available implementations or their features. Readers are advised to note that other implementations may exist.

According to [BCP205], "this will allow reviewers and working groups to assign due consideration to documents that have the benefit of running code, which may serve as evidence of valuable experimentation and feedback that have made the implemented protocols more mature. It is up to the individual working groups to use this information as they see fit".

9.1. Implementer

The open-source implementation was initiated and is maintained by the Fraunhofer Institute for Secure Information Technology - SIT.

9.2. Implementation Name

The open-source implementation is named "CHAllenge-Response based Remote Attestation" or in short: CHARRA.

9.3. Implementation URL

The open-source implementation project resource can be located via: https://github.com/Fraunhofer-SIT/charra

9.4. Maturity

The code’s level of maturity is considered to be "prototype".

9.5. Coverage and Version Compatibility

The current version (‘1bcb469’) implements a challenge/response interaction model and is aligned with the exemplary specification of the CoAP FETCH bodies defined in Section Appendix A of this document.

Birkholz, et al. Expires 30 July 2022
9.6. License

The CHARRA project and all corresponding code and data maintained on GitHub are provided under the BSD 3-Clause "New" or "Revised" license.

9.7. Implementation Dependencies

The implementation requires the use of the official Trusted Computing Group (TCG) open-source Trusted Software Stack (TSS) for the Trusted Platform Module (TPM) 2.0. The corresponding code and data is also maintained on GitHub and the project resources can be located via: https://github.com/tpm2-software/tpm2-tss/

9.8. Contact

Michael Eckel (michael.eckel@sit.fraunhofer.de)

10. Security and Privacy Considerations

In a remote attestation procedure the Verifier or the Attester MAY want to cryptographically blind several attributes. For instance, information can be part of the signature after applying a one-way function (e. g. a hash function).

There is also a possibility to scramble the Nonce or Attester Identity with other information that is known to both the Verifier and Attester. A prominent example is the IP address of the Attester that usually is known by the Attester itself as well as the Verifier. This extra information can be used to scramble the Nonce in order to counter certain types of relay attacks.

Appendix A. CDDL Specification for a simple CoAP Challenge/Response Interaction

The following CDDL specification is an exemplary proof-of-concept to illustrate a potential implementation of the Challenge/Response Interaction Model. The transfer protocol used is CoAP using the FETCH operation. The actual resource operated on can be empty. Both the Challenge Message and the Response Message are exchanged via the FETCH operation and corresponding FETCH Request and FETCH Response body.

In this example, evidence is created via the root-of-trust for reporting primitive operation "quote" that is provided by a TPM 2.0.
RAIM-Bodies = CoAP-FETCH-Body / CoAP-FETCH-Response-Body

CoAP-FETCH-Body = [ hello: bool, ; if true, the AK-Cert is conveyed
   nonce: bytes,
   pcr-selection: [ + [ tcg-hash-alg-id: uint .size 2, ; TPM2
      _ALG_ID
         [ + pcr: uint .size 1 ],
      ],
   ],
]

CoAP-FETCH-Response-Body = [ attestations-evidence: TPMS_ATTEST-quote,
   tpm-native-signature: bytes,
   ? ak-cert: bytes, ; attestation key certificate
]

TPMS_ATTEST-quote = [ qualifiedSigner: uint .size 2, ;TPM2B_NAME
   TPMS_CLOCK_INFO,
   firmwareVersion: uint .size 8
   quote-responses: [ * [ pcr: uint .size 1,
      + [ pcr-value: bytes,
         ? hash-alg-id: uint .size 2,
      ],
      ],
      ? pcr-digest: bytes,
   ],

TPMS_CLOCK_INFO = [ clock: uint .size 8,
   resetCounter: uint .size 4,
   restartCounter: uint .size 4,
   save: bool,
]

TPM-based Network Device Remote Integrity Verification

draft-ietf-rats-tpm-based-network-device-attest-14

Abstract

This document describes a workflow for remote attestation of the integrity of firmware and software installed on network devices that contain Trusted Platform Modules [TPM1.2], [TPM2.0], as defined by the Trusted Computing Group (TCG), or equivalent hardware implementations that include the protected capabilities, as provided by TPMs.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 23 September 2022.

1. Introduction

There are many aspects to consider in fielding a trusted computing device, from operating systems to applications. Mechanisms to prove that a device installed at a customer’s site is authentic (i.e., not counterfeit) and has been configured with authorized software, all as part of a trusted supply chain, are just a few of the many aspects which need to be considered concurrently to have confidence that a device is truly trustworthy.

A generic architecture for remote attestation has been defined in [I-D.ietf-rats-architecture]. Additionally, use cases for remotely attesting networking devices are discussed within Section 6 of [I-D.richardson-rats-usecases]. However, these documents do not provide sufficient guidance for network equipment vendors and operators to design, build, and deploy interoperable devices.

The intent of this document is to provide such guidance. It does this by outlining the Remote Integrity Verification (RIV) problem, and then identifies elements that are necessary to get the complete, scalable attestation procedure working with commercial networking products such as routers, switches and firewalls. An underlying assumption will be the availability within the device of a Trusted Platform Module [TPM1.2], [TPM2.0] compatible cryptoprocessor to enable the trustworthy remote assessment of the device’s software and hardware.

1.1. Requirements notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

1.2. Terminology

A number of terms are reused from [I-D.ietf-rats-architecture]. These include: Appraisal Policy for Evidence, Attestation Result, Attester, Evidence, Reference Value, Relying Party, Verifier, and Verifier Owner.
Additionally, this document defines the following term:

Attestation: the process of generating, conveying and appraising claims, backed by evidence, about device trustworthiness characteristics, including supply chain trust, identity, device provenance, software configuration, device composition, compliance to test suites, functional and assurance evaluations, etc.

The goal of attestation is simply to assure an administrator or auditor that the device configuration and software that was launched when the device was last started is authentic and untampered-with. The determination of software authenticity is not prescribed in this document, but it’s typically taken to mean a software image generated by an authority trusted by the administrator, such as the device manufacturer.

Within the Trusted Computing Group (TCG) context, the scope of attestation is typically narrowed to describe the process by which an independent Verifier can obtain cryptographic proof as to the identity of the device in question, and evidence of the integrity of software loaded on that device when it started up, and then verify that what’s there matches the intended configuration. For network equipment, a Verifier capability can be embedded in a Network Management Station (NMS), a posture collection server, or other network analytics tool (such as a software asset management solution, or a threat detection and mitigation tool, etc.). While informally referred to as attestation, this document focuses on a specific subset of attestation tasks, defined here as Remote Integrity Verification (RIV). RIV in this document takes a network-equipment-centric perspective that includes a set of protocols and procedures for determining whether a particular device was launched with authentic software, starting from Roots of Trust. While there are many ways to accomplish attestation, RIV sets out a specific set of protocols and tools that work in environments commonly found in network equipment. RIV does not cover other device characteristics that could be attested (e.g., geographic location, connectivity; see [I-D.richardson-rats-ucases]), although it does provide evidence of a secure infrastructure to increase the level of trust in other device characteristics attested by other means (e.g., by Entity Attestation Tokens [I-D.ietf-rats-eat]).

In line with [I-D.ietf-rats-architecture] definitions, this document uses the term Endorser to refer to the role that signs identity and attestation certificates used by the Attester, while Reference Values are signed by a Reference Value Provider. Typically, the manufacturer of a network device would be accepted as both the Endorser and Reference Value Provider, although the choice is ultimately up to the Verifier Owner.
1.3. Document Organization

The remainder of this document is organized into several sections:

* The remainder of this section covers goals and requirements, plus a top-level description of RIV.

* The Solution Overview section outlines how Remote Integrity Verification works.

* The Standards Components section links components of RIV to normative standards.

* Privacy and Security shows how specific features of RIV contribute to the trustworthiness of the Attestation Result.

* Supporting material is in an appendix at the end.

1.4. Goals

Network operators benefit from a trustworthy attestation mechanism that provides assurance that their network comprises authentic equipment, and has loaded software free of known vulnerabilities and unauthorized tampering. In line with the overall goal of assuring integrity, attestation can be used to assist in asset management, vulnerability and compliance assessment, plus configuration management.

The RIV attestation workflow outlined in this document is intended to meet the following high-level goals:

* Provable Device Identity - This specification requires that an Attester (i.e., the attesting device) includes a cryptographic identifier unique to each device. Effectively this means that the device’s TPM must be so provisioned during the manufacturing cycle.

* Software Inventory - A key goal is to identify the software release(s) installed on the Attester, and to provide evidence that the software stored within hasn’t been altered without authorization.

* Verifiability - Verification of software and configuration of the device shows that the software that the administrator authorized for use was actually launched.
In addition, RIV is designed to operate either in a centralized environment, such as with a central authority that manages and configures a number of network devices, or 'peer-to-peer', where network devices independently verify one another to establish a trust relationship. (See Section 3.3 below)

1.5. Description of Remote Integrity Verification (RIV)

Attestation requires two interlocking mechanisms between the Attester network device and the Verifier:

* Device Identity, the mechanism providing trusted identity, can reassure network managers that the specific devices they ordered from authorized manufacturers for attachment to their network are those that were installed, and that they continue to be present in their network. As part of the mechanism for Device Identity, cryptographic proof of the identity of the manufacturer is also provided.

* Software Measurement is the mechanism that reports the state of mutable software components on the device, and can assure administrators that they have known, authentic software configured to run in their network.

Using these two interlocking mechanisms, RIV is a component in a chain of procedures that can assure a network operator that the equipment in their network can be reliably identified, and that authentic software of a known version is installed on each device. Equipment in the network includes devices that make up the network itself, such as routers, switches and firewalls.

Software used to boot a device can be identified by a chain of measurements, anchored at the start by a Root of Trust for Measurement (see Section 9.2), each measuring the next stage and recording the result in tamper-resistant storage, normally ending when the system software is fully loaded. A measurement signifies the identity, integrity and version of each software component registered with an Attester's TPM [TPM1.2], [TPM2.0], so that a subsequent verification stage can determine if the software installed is authentic, up-to-date, and free of tampering.

RIV includes several major processes, split between the Attester and Verifier:

1. Generation of Evidence is the process whereby an Attester generates cryptographic proof (Evidence) of claims about device properties. In particular, the device identity and its software configuration are both of critical importance.
2. Device Identification refers to the mechanism assuring the Relying Party (ultimately, a network administrator) of the identity of devices that make up their network, and that their manufacturers are known.

3. Conveyance of Evidence reliably transports the collected Evidence from Attester to a Verifier to allow a management station to perform a meaningful appraisal in Step 4. The transport is typically carried out via a management network. While not required for reliable attestation, an encrypted channel may be used to provide integrity, authenticity, or confidentiality once attestation is complete. It should be noted that critical attestation evidence from the TPM is signed by a key known only to TPM, and is not dependent on encryption carried out as part of a reliable transport.

4. Finally, Appraisal of Evidence occurs. This is the process of verifying the Evidence received by a Verifier from the Attester, and using an Appraisal Policy to develop an Attestation Result, used to inform decision-making. In practice, this means comparing the Attester’s measurements reported as Evidence with the device configuration expected by the Verifier. Subsequently, the Appraisal Policy for Evidence might match Evidence found against Reference Values (aka Golden Measurements), which represent the intended configured state of the connected device.

All implementations supporting this RIV specification require the support of the following three technologies:

1. Identity: Device identity in RIV is based on IEEE 802.1AR Device Identity (DevID) [IEEE-802-1AR], coupled with careful supply-chain management by the manufacturer. The Initial DevID (IDevID) certificate contains a statement by the manufacturer that establishes the identity of the device as it left the factory. Some applications with a more-complex post-manufacture supply chain (e.g., Value Added Resellers), or with different privacy concerns, may want to use alternative mechanisms for platform authentication (for example, TCG Platform Certificates [Platform-Certificates], or post-manufacture installation of Local Device ID (LDevID)).

2. Platform Attestation provides evidence of configuration of software elements present in the device. This form of attestation can be implemented with TPM Platform Configuration Registers (PCRs), Quote and Log mechanisms, which provide cryptographically authenticated evidence to report what software was started on the device through the boot cycle. Successful attestation requires an unbroken chain from a boot-time root of
trust through all layers of software needed to bring the device to an operational state, in which each stage computes the hash of components of the next stage, then updates the attestation log and the TPM. The TPM can then report the hashes of all the measured hashes as signed evidence called a Quote (see Section 9.1 for an overview of TPM operation, or [TPM1.2] and [TPM2.0] for many more details).

3. Signed Reference Values (aka Reference Integrity Measurements) must be conveyed from the Reference Value Provider (the entity accepted as the software authority, often the manufacturer of the network device) to the Verifier.

1.6. Solution Requirements

Remote Integrity Verification must address the "Lying Endpoint" problem, in which malicious software on an endpoint may subvert the intended function, and also prevent the endpoint from reporting its compromised status. (See Section 5 for further Security Considerations.)

RIV attestation is designed to be simple to deploy at scale. RIV should work "out of the box" as far as possible, that is, with the fewest possible provisioning steps or configuration databases needed at the end-user’s site. Network equipment is often required to "self-configure", to reliably reach out without manual intervention to prove its identity and operating posture, then download its own configuration, a process which precludes pre-installation configuration. See [RFC8572] for an example of Secure Zero Touch Provisioning.

1.7. Scope

The need for assurance of software integrity, addressed by Remote Attestation, is a very general problem that could apply to most network-connected computing devices. However, this document includes several assumptions that limit the scope to network equipment (e.g., routers, switches and firewalls):

* This solution is for use in non-privacy-preserving applications (for example, networking, Industrial IoT), avoiding the need for a Privacy Certificate Authority (also called an Attestation CA) for attestation keys [AK-Enrollment] or TCG Platform Certificates [Platform-Certificates].

* This document assumes network protocols that are common in network equipment such as YANG [RFC7950] and NETCONF [RFC6241], but not generally used in other applications.
The approach outlined in this document mandates the use of a TPM [TPM1.2], [TPM2.0], or a compatible cryptoprocessor.

1.7.1. Out of Scope

* Run-Time Attestation: The Linux Integrity Measurement Architecture [IMA] attests each process launched after a device is started (and is in scope for RIV in general), but continuous run-time attestation of Linux or other multi-threaded operating system processes after the OS has started considerably expands the scope of the problem. Many researchers are working on that problem, but this document defers the problem of continuous, in-memory run-time attestation.

* Multi-Vendor Embedded Systems: Additional coordination would be needed for devices that themselves comprise hardware and software from multiple vendors, integrated by the end user. Although out of scope for this document, these issues are accommodated in [I-D.ietf-rats-architecture].

* Processor Sleep Modes: Network equipment typically does not "sleep", so sleep and hibernate modes are not considered. Although out of scope for RIV in this document, Trusted Computing Group specifications do encompass sleep and hibernate states, which could be incorporated into remote attestation for network equipment in the future, given a compelling need.

* Virtualization and Containerization: In a non-virtualized system, the host OS is responsible for measuring each User Space file or process throughout the operational lifetime of the system. For virtualized systems, the host OS must verify the hypervisor, but then the hypervisor must manage its own chain of trust through the virtual machine. Virtualization and containerization technologies are increasingly used in network equipment, but are not considered in this document.

2. Solution Overview

2.1. RIV Software Configuration Attestation using TPM

RIV Attestation is a process which can be used to determine the identity of software running on a specifically-identified device. The Remote Attestation steps of Section 1.5 are broken into two phases, shown in Figure 1:

* During system startup, or boot phase, each distinct software object is "measured" by the Attester. The object’s identity, hash (i.e., cryptographic digest) and version information are recorded
in a log. Hashes are also extended into the TPM (see Section 9.1 for more on 'extending hashes'), in a way that can be used to validate the log entries. The measurement process generally follows the layered chain-of-trust model used in Measured Boot, where each stage of the system measures the next one, and extends its measurement into the TPM, before launching it. See [I-D.ietf-rats-architecture], section "Layered Attestation Environments," for an architectural definition of this model.

* Once the device is running and has operational network connectivity, verification can take place. A separate Verifier, running in its own trusted environment, will interrogate the network device to retrieve the logs and a copy of the digests collected by hashing each software object, signed by an attestation private key secured by, but never released by, the TPM. The YANG model described in [I-D.ietf-rats-yang-tpm-charra] facilitates this operation.

The result is that the Verifier can verify the device’s identity by checking the subject[RFC5280] and signature of the certificate containing the TPM’s attestation public key, and can validate the software that was launched by verifying the correctness of the logs by comparing with the signed digests from the TPM, and comparing digests in the log with Reference Values.

It should be noted that attestation and identity are inextricably linked; signed Evidence that a particular version of software was loaded is of little value without cryptographic proof of the identity of the Attester producing the Evidence.
In the Boot phase, measurements are "extended", or hashed, into the TPM as processes start, with the result that the TPM ends up containing hashes of all the measured hashes. Later, once the system is operational, during the Verification phase, signed digests are retrieved from the TPM for off-box analysis.

2.1.1. What Does RIV Attest?

TPM attestation is focused on Platform Configuration Registers (PCRs), but those registers are only vehicles for certifying accompanying Evidence, conveyed in log entries. It is the hashes in log entries that are extended into PCRs, where the final PCR values can be retrieved in the form of a structure called a Quote, signed by an Attestation key known only to the TPM. The use of multiple PCRs serves only to provide some independence between different classes of object, so that one class of objects can be updated without changing the extended hash for other classes. Although PCRs can be used for any purpose, this section outlines the objects within the scope of this document which may be extended into the TPM.

In general, assignment of measurements to PCRs is a policy choice made by the device manufacturer, selected to independently attest three classes of object:
* Code, (i.e., instructions) to be executed by a CPU.

* Configuration - Many devices offer numerous options controlled by non-volatile configuration variables which can impact the device’s security posture. These settings may have vendor defaults, but often can be changed by administrators, who may want to verify via attestation that the operational state of the settings match their intended state.

* Credentials - Administrators may wish to verify via attestation that public keys and credentials outside the Root of Trust have not been subject to unauthorized tampering. (By definition, keys protecting the root of trust can’t be verified independently.)

The TCG PC Client Platform Firmware Profile Specification [PC-Client-BIOS-TPM-2.0] gives considerable detail on what is to be measured during the boot phase of platform startup using a UEFI BIOS (www.uefi.org), but the goal is simply to measure every bit of code executed in the process of starting the device, along with any configuration information related to security posture, leaving no gap for unmeasured code to remain undetected, potentially subverting the chain.

For devices using a UEFI BIOS, [PC-Client-BIOS-TPM-2.0] and [PC-Client-EFI-TPM-1.2] give detailed normative requirements for PCR usage. For other platform architectures, where TCG normative requirements currently do not exist, the table in Figure 2 gives non-normative guidance for PCR assignment that generalizes the specific details of [PC-Client-BIOS-TPM-2.0].

By convention, most PCRs are assigned in pairs, which the even-numbered PCR used to measure executable code, and the odd-numbered PCR used to measure whatever data and configuration are associated with that code. It is important to note that each PCR may contain results from dozens (or even thousands) of individual measurements.

2.1.2. Notes on PCR Allocations

It is important to recognize that PCR[0] is critical. The first measurement into PCR[0] is taken by the Root of Trust for Measurement, code which, by definition, cannot be verified by measurement. This measurement establishes the chain of trust for all subsequent measurements. If the PCR[0] measurement cannot be trusted, the validity of the entire chain is put into question.

Distinctions Between PCR[0], PCR[2], PCR[4] and PCR[8] are summarized below:

* PCR[0] typically represents a consistent view of rarely-changed Host Platform boot components, allowing Attestation policies to be defined using the less changeable components of the transitive trust chain. This PCR typically provides a consistent view of the platform regardless of user selected options.
* PCR[2] is intended to represent a "user configurable" environment where the user has the ability to alter the components that are measured into PCR[2]. This is typically done by adding adapter cards, etc., into user-accessible PCI or other slots. In UEFI systems these devices may be configured by Option ROMs measured into PCR[2] and executed by the UEFI BIOS.

* PCR[4] is intended to represent the software that manages the transition between the platform's Pre-Operating System start and the state of a system with the Operating System present. This PCR, along with PCR[5], identifies the initial operating system loader (e.g., GRUB for Linux).

* PCR[8] is used by the OS loader (e.g. GRUB) to record measurements of the various components of the operating system.

Although the TCG PC Client document specifies the use of the first eight PCRs very carefully to ensure interoperability among multiple UEFI BIOS vendors, it should be noted that embedded software vendors may have considerably more flexibility. Verifiers typically need to know which log entries are consequential and which are not (possibly controlled by local policies) but the Verifier may not need to know what each log entry means or why it was assigned to a particular PCR. Designers must recognize that some PCRs may cover log entries that a particular Verifier considers critical and other log entries that are not considered important, so differing PCR values may not on their own constitute a check for authenticity. For example, in a UEFI system, some administrators may consider booting an image from a removable drive, something recorded in a PCR, to be a security violation, while others might consider that operation an authorized recovery procedure.

Designers may allocate particular events to specific PCRs in order to achieve a particular objective with local attestation, (e.g., allowing a procedure to execute, or releasing a particular decryption key, only if a given PCR is in a given state). It may also be important to designers to consider whether streaming notification of PCR updates is required (see [I-D.birkholz-rats-network-device-subscription]). Specific log entries can only be validated if the Verifier receives every log entry affecting the relevant PCR, so (for example) a designer might want to separate rare, high-value events such as configuration changes, from high-volume, routine measurements such as IMA [IMA] logs.
2.2. RIV Keying

RIV attestation relies on two credentials:

* An identity key pair and matching certificate is required to certify the identity of the Attester itself. RIV specifies the use of an IEEE 802.1AR Device Identity (DevID) [IEEE-802-1AR], signed by the device manufacturer, containing the device serial number. This requirement goes slightly beyond 802.1AR; see Section 2.4 for notes.

* An Attestation key pair and matching certificate is required to sign the Quote generated by the TPM to report evidence of software configuration.

In a TPM application, both the Attestation private key and the DevID private key MUST be protected by the TPM. Depending on other TPM configuration procedures, the two keys are likely to be different; some of the considerations are outlined in TCG "TPM 2.0 Keys for Device Identity and Attestation" [Platform-DevID-TPM-2.0].

The TCG TPM 2.0 Keys document [Platform-DevID-TPM-2.0] specifies further conventions for these keys:

* When separate Identity and Attestation keys are used, the Attestation Key (AK) and its X.509 certificate should parallel the DevID, with the same unique device identification as the DevID certificate (that is, the same subject and subjectAltName (if present), even though the key pairs are different). This allows a quote from the device, signed by an AK, to be linked directly to the device that provided it, by examining the corresponding AK certificate. If the subject in the AK certificate doesn’t match the corresponding DevID certificate, or they’re signed by differing authorities the Verifier may signal the detection of an Asokan-style person-in-the-middle attack (see Section 5.2).

* Network devices that are expected to use secure zero touch provisioning as specified in [RFC8572] MUST be shipped by the manufacturer with pre-provisioned keys (Initial DevID and Initial AK, called IDevID and IAK). IDevID and IAK certificates MUST both be signed by the Endorser (typically the device manufacturer). Inclusion of an IDevID and IAK by a vendor does not preclude a mechanism whereby an administrator can define Local Identity and Attestation Keys (LDevID and LAK) if desired.
2.3. RIV Information Flow

RIV workflow for network equipment is organized around a simple use case where a network operator wishes to verify the integrity of software installed in specific, fielded devices. A normative taxonomy of terms is given in [I-D.ietf-rats-architecture], but as a reminder, this use case implies several roles and objects:

1. The Attester, the device which the network operator wants to examine.

2. A Verifier (which might be a network management station) somewhere separate from the Device that will retrieve the signed evidence and measurement logs, and analyze them to pass judgment on the security posture of the device.

3. A Relying Party, which can act on Attestation Results. Interaction between the Relying Party and the Verifier is considered out of scope for RIV.

4. Signed Reference Integrity Manifests (RIMs), containing Reference Values, can either be created by the device manufacturer and shipped along with the device as part of its software image, or alternatively, could be obtained several other ways (direct to the Verifier from the manufacturer, from a third party, from the owner’s observation of what’s thought to be a "known good system", etc.). Retrieving RIMs from the device itself allows attestation to be done in systems that may not have access to the public internet, or by other devices that are not management stations per se (e.g., a peer device; see Section 3.1.3). If Reference Values are obtained from multiple sources, the Verifier may need to evaluate the relative level of trust to be placed in each source in case of a discrepancy.

These components are illustrated in Figure 3.
Figure 3: RIV Reference Configuration for Network Equipment

* In Step 0, The Reference Value Provider (the device manufacturer or other authority) makes one or more Reference Integrity Manifests (RIMs), corresponding to the software image expected to be found on the device, signed by the Reference Value Provider, available to the Verifier (see Section 3.1.3 for "in-band" and "out of band" ways to make this happen).

* In Step 1, the Verifier (Network Management Station), on behalf of a Relying Party, requests Identity, Measurement Values, and possibly RIMs, from the Attester.

* In Step 2, the Attester responds to the request by providing a DevID, quotes (measured values, signed by the Attester), and optionally RIMs.

Use of the following standards components allows for interoperability:

1. TPM Keys MUST be configured according to [Platform-DevID-TPM-2.0], or [Platform-ID-TPM-1.2].

2. For devices using UEFI and Linux, measurements of firmware and bootable modules MUST be taken according to TCG PC Client [PC-Client-EFI-TPM-1.2] or [PC-Client-BIOS-TPM-2.0], and Linux IMA [IMA].

3. Device Identity MUST be managed as specified in IEEE 802.1AR Device Identity certificates [IEEE-802-1AR], with keys protected by TPMs.

4. Attestation logs from Linux-based systems MUST be formatted according to the Canonical Event Log format [Canonical-Event-Log]. UEFI-based systems MUST use the TCG UEFI BIOS event log [PC-Client-EFI-TPM-1.2] for TPM1.2 systems, and TCG PC Client Platform Firmware Profile [PC-Client-BIOS-TPM-2.0] for TPM2.0.

5. Quotes MUST be retrieved from the TPM according to TCG TAP Information Model [TAP] and the CHARRA YANG model [I-D.ietf-rats-yang-tpm-charra]. While the TAP IM gives a protocol-independent description of the data elements involved, it’s important to note that quotes from the TPM are signed inside the TPM, and MUST be retrieved in a way that does not invalidate the signature, to preserve the trust model. The [I-D.ietf-rats-yang-tpm-charra] is used for this purpose. (See Section 5 Security Considerations).
6. Reference Values MUST be encoded as defined in the TCG RIM document [RIM], typically using SWID [SWID], [NIST-IR-8060] or CoSWID tags [I-D.ietf-sacm-coswid].

2.4. RIV Simplifying Assumptions

This document makes the following simplifying assumptions to reduce complexity:

* The product to be attested MUST be shipped by the equipment vendor with both an IEEE 802.1AR Device Identity and an Initial Attestation Key (IAK), with certificates in place. The IAK certificate must contain the same identity information as the DevID (specifically, the same subject and subjectAltName (if used), signed by the manufacturer). The IAK is a type of key that can be used to sign a TPM Quote, but not other objects (i.e., it's marked as a TCG "Restricted" key; this convention is described in "TPM 2.0 Keys for Device Identity and Attestation" [Platform-DevID-TPM-2.0]). For network equipment, which is generally non-privacy-sensitive, shipping a device with both an IDevID and an IAK already provisioned substantially simplifies initial startup.

* IEEE 802.1AR does not require a product serial number as part of the subject, but RIV-compliant devices MUST include their serial numbers in the DevID/IAK certificates to simplify tracking logistics for network equipment users. All other optional 802.1AR fields remain optional in RIV.

It should be noted that 802.1AR use of X.509 certificate fields is not identical to those described in [RFC6125] for representation of application service identity.

* The product MUST be equipped with a Root of Trust for Measurement (RTM), Root of Trust for Storage and Root of Trust for Reporting (as defined in [SP800-155]) which together are capable of conforming to TCG Trusted Attestation Protocol Information Model [TAP].

* The authorized software supplier MUST make available Reference Values in the form of signed SWID or CoSWID tags.

2.4.1. Reference Integrity Manifests (RIMs)

[I-D.ietf-rats-yang-tpm-charra] focuses on collecting and transmitting evidence in the form of PCR measurements and attestation logs. But the critical part of the process is enabling the Verifier to decide whether the measurements are "the right ones" or not.
While it must be up to network administrators to decide what they want on their networks, the software supplier should supply the Reference Values, in signed Reference Integrity Manifests, that may be used by a Verifier to determine if evidence shows known good, known bad or unknown software configurations.

In general, there are two kinds of reference measurements:

1. Measurements of early system startup (e.g., BIOS, boot loader, OS kernel) are essentially single-threaded, and executed exactly once, in a known sequence, before any results could be reported. In this case, while the method for computing the hash and extending relevant PCRs may be complicated, the net result is that the software (more likely, firmware) vendor will have one known good PCR value that "should" be present in the relevant PCRs after the box has booted. In this case, the signed reference measurement could simply list the expected hashes for the given version. However, a RIM that contains the intermediate hashes can be useful in debugging cases where the expected final hash is not the one reported.

2. Measurements taken later in operation of the system, once an OS has started (for example, Linux IMA [IMA]), may be more complex, with unpredictable "final" PCR values. In this case, the Verifier must have enough information to reconstruct the expected PCR values from logs and signed reference measurements from a trusted authority.

In both cases, the expected values can be expressed as signed SWID or CoSWID tags, but the SWID structure in the second case is somewhat more complex, as reconstruction of the extended hash in a PCR may involve thousands of files and other objects.

TCG has published an information model defining elements of Reference Integrity Manifests under the title TCG Reference Integrity Manifest Information Model [RIM]. This information model outlines how SWID tags should be structured to allow attestation, and defines "bundles" of SWID tags that may be needed to describe a complete software release. The RIM contains metadata relating to the software release it belongs to, plus hashes for each individual file or other object that could be attested.

Many network equipment vendors use a UEFI BIOS to launch their network operating system. These vendors may want to also use the TCG PC Client Reference Integrity Measurement specification [PC-Client-RIM], which focuses specifically on a SWID-compatible format suitable for expressing measurement values expected from a UEFI BIOS.
2.4.2. Attestation Logs

Quotes from a TPM can provide evidence of the state of a device up to the time the evidence was recorded, but to make sense of the quote in cases where several events are extended into one PCR an event log that identifies which software modules contributed which values to the quote during startup must also be provided. When required, the log MUST contain enough information to demonstrate its integrity by allowing exact reconstruction of the digest conveyed in the signed quote (that is, calculating the hash of all the hashes in the log should produce the same values as contained in the PCRs; if they don’t match, the log may have been tampered with. See Section 9.1).

There are multiple event log formats which may be supported as viable formats of Evidence between the Attester and Verifier, but to simplify interoperability, RIV focuses on just three:

* TCG UEFI BIOS event log for TPM 2.0 (TCG PC Client Platform Firmware Profile) [PC-Client-BIOS-TPM-2.0]

* TCG UEFI BIOS event log for TPM 1.2 (TCG EFI Platform Specification for TPM Family 1.1 or 1.2, Section 7) [PC-Client-EFI-TPM-1.2]

* TCG Canonical Event Log [Canonical-Event-Log]

3. Standards Components

3.1. Prerequisites for RIV

The Reference Interaction Model for Challenge-Response-based Remote Attestation ([I-D.birkholz-rats-reference-interaction-model]) is based on the standard roles defined in [I-D.ietf-rats-architecture]. However, additional prerequisites have been established to allow for interoperable RIV use case implementations. These prerequisites are intended to provide sufficient context information so that the Verifier can acquire and evaluate measurements collected by the Attester.

3.1.1. Unique Device Identity

A secure Device Identity (DevID) in the form of an IEEE 802.1AR DevID certificate [IEEE-802-1AR] must be provisioned in the Attester’s TPMs.
3.1.2. Keys

The Attestation Key (AK) and certificate must also be provisioned on the Attester according to [Platform-DevID-TPM-2.0], or [Platform-ID-TPM-1.2].

It MUST be possible for the Verifier to determine that the Attester’s Attestation keys are resident in the same TPM as its DevID keys (see Section 2.2 and Section 5 Security Considerations).

3.1.3. Appraisal Policy for Evidence

As noted in Section 2.3, the Verifier may obtain Reference Values from several sources. In addition, administrators may make authorized, site-specific changes (e.g. keys in key databases) that could impact attestation results. As such, there could be conflicts, omissions or ambiguities between some Reference Values and collected Evidence.

The Verifier MUST have an Appraisal Policy for Evidence to evaluate the significance of any discrepancies between different reference sources, or between reference values and evidence from logs and quotes. While there must be an Appraisal Policy, this document does not specify the format or mechanism to convey the intended policy, nor does RIV specify mechanisms by which the results of applying the policy are communicated to the Relying Party.

3.2. Reference Model for Challenge-Response

Once the prerequisites for RIV are met, a Verifier is able to acquire Evidence from an Attester. The following diagram illustrates a RIV information flow between a Verifier and an Attester, derived from Section 7.1 of [I-D.birkholz-rats-reference-interaction-model]. In this diagram, each event with its input and output parameters is shown as "Event(input-params) => (outputs)". Event times shown correspond to the time types described within Appendix A of [I-D.ietf-rats-architecture]:

* Step 1 (time(VG)): One or more Attesting Network Device PCRs are extended with measurements. RIV provides no direct link between the time at which the event takes place and the time that it's attested, although streaming attestation as in [I-D.birkholz-rats-network-device-subscription] could.

* Step 2 (time(NS)): The Verifier generates a unique random nonce ("number used once"), and makes a request for one or more PCRs from an Attester. For interoperability, this must be accomplished as specified in the YANG Data Model for Challenge-Response-based Remote Attestation Procedures using TPMs [I-D.ietf-rats-yang-tpm-charra]. TPM1.2 and TPM2.0 both allow nonces as large as the operative digest size (i.e., 20 or 32 bytes; see [TPM1.2] Part 2, Section 5.5 and [TPM2.0] Part 2, Section 10.4.4).

* Step 3 (time(EG)): On the Attester, measured values are retrieved from the Attester’s TPM. This requested PCR evidence, along with the Verifier’s nonce, called a Quote, is signed by the Attestation Key (AK) associated with the DevID. Quotes are retrieved according to CHARRA YANG model [I-D.ietf-rats-yang-tpm-charra].
At the same time, the Attester collects log evidence showing the values have been extended into that PCR. Section 9.1 gives more detail on how this works, including references to the structure and contents of quotes in TPM documents.

* Step 4: Collected Evidence is passed from the Attester to the Verifier

* Step 5 (time(RG,RA)): The Verifier reviews the Evidence and takes action as needed. As the interaction between Relying Party and Verifier is out of scope for RIV, this can be described as one step.

- If the signature covering TPM Evidence is not correct, the device SHOULD NOT be trusted.

- If the nonce in the response doesn’t match the Verifier’s nonce, the response may be a replay, and device SHOULD NOT be trusted.

- If the signed PCR values do not match the set of log entries which have extended a particular PCR, the device SHOULD NOT be trusted.

- If the log entries that the Verifier considers important do not match known good values, the device SHOULD NOT be trusted. We note that the process of collecting and analyzing the log can be omitted if the value in the relevant PCR is already a known-good value.

- If the set of log entries are not seen as acceptable by the Appraisal Policy for Evidence, the device SHOULD NOT be trusted.

- If time(RG)-time(NS) is greater than the Appraisal Policy for Evidence’s threshold for assessing freshness, the Evidence is considered stale and SHOULD NOT be trusted.

3.2.1. Transport and Encoding

Network Management systems may retrieve signed PCR based Evidence using NETCONF or RESTCONF with [I-D.ietf-rats-yang-tpm-charra]. In either case, implementatations must do so using a secure tunnel.

Log Evidence MUST be retrieved via log interfaces specified in [I-D.ietf-rats-yang-tpm-charra].
3.3. Centralized vs Peer-to-Peer

Figure 4 above assumes that the Verifier is trusted, while the Attester is not. In a Peer-to-Peer application such as two routers negotiating a trust relationship, the two peers can each ask the other to prove software integrity. In this application, the information flow is the same, but each side plays a role both as an Attester and a Verifier. Each device issues a challenge, and each device responds to the other’s challenge, as shown in Figure 5. Peer-to-peer challenges, particularly if used to establish a trust relationship between routers, require devices to carry their own signed reference measurements (RIMs). Devices may also have to carry Appraisal Policy for Evidence for each possible peer device so that each device has everything needed for remote attestation, without having to resort to a central authority.

Figure 5: Peer-to-Peer Attestation Information Flow
In this application, each device may need to be equipped with signed RIMs to act as an Attester, and also an Appraisal Policy for Evidence and a selection of trusted X.509 root certificates, to allow the device to act as a Verifier. An existing link layer protocol such as 802.1X [IEEE-802.1X] or 802.1AE [IEEE-802.1AE], with Evidence being enclosed over a variant of EAP [RFC3748] or LLDP [LLDP] are suitable methods for such an exchange. Details of peer-to-peer operation are out of scope for this document.

4. Privacy Considerations

Network equipment, such as routers, switches and firewalls, has a key role to play in guarding the privacy of individuals using the network. Network equipment generally adheres to several rules to protect privacy:

* Packets passing through the device must not be sent to unauthorized destinations. For example:

  - Routers often act as Policy Enforcement Points, where individual subscribers may be checked for authorization to access a network. Subscriber login information must not be released to unauthorized parties.

  - Network equipment is often called upon to block access to protected resources from unauthorized users.

* Routing information, such as the identity of a router’s peers, must not be leaked to unauthorized neighbors.

* If configured, encryption and decryption of traffic must be carried out reliably, while protecting keys and credentials.

Functions that protect privacy are implemented as part of each layer of hardware and software that makes up the networking device. In light of these requirements for protecting the privacy of users of the network, the network equipment must identify itself, and its boot configuration and measured device state (for example, PCR values), to the equipment’s administrator, so there’s no uncertainty as to what function each device and configuration is configured to carry out. Attestation is a component that allows the administrator to ensure that the network provides individual and peer privacy guarantees, even though the device itself may not have a right to keep its identity secret.

See [NetEq] for more context on privacy in networking devices.
While attestation information from network devices is not likely to contain privacy-sensitive content regarding network users, administrators may want to keep attestation records confidential to avoid disclosing versions of software loaded on the device, information which could facilitate attacks against known vulnerabilities.

5. Security Considerations

Specifications such as [RFC8446] (TLS) and [RFC7950] (YANG) contain considerable advice on keeping network-connected systems secure. This section outlines specific risks and mitigations related to attestation.

Attestation Evidence obtained by the RIV procedure is subject to a number of attacks:

* Keys may be compromised.

* A counterfeit device may attempt to impersonate (spoof) a known authentic device.

* Person-in-the-middle attacks may be used by a compromised device to attempt to deliver responses that originate in an authentic device.

* Replay attacks may be attempted by a compromised device.

5.1. Keys Used in RIV

Trustworthiness of RIV attestation depends strongly on the validity of keys used for identity and attestation reports. RIV takes full advantage of TPM capabilities to ensure that evidence can be trusted.

Two sets of key-pairs are relevant to RIV attestation:

* A DevID key-pair is used to certify the identity of the device in which the TPM is installed.

* An Attestation Key-pair (AK) key is used to certify attestation Evidence (called ‘quotes’ in TCG documents), used to provide evidence for integrity of the software on the device.

TPM practices usually require that these keys be different, as a way of ensuring that a general-purpose signing key cannot be used to spoof an attestation quote.
In each case, the private half of the key is known only to the TPM, and cannot be retrieved externally, even by a trusted party. To ensure that’s the case, specification-compliant private/public key-pairs are generated inside the TPM, where they are never exposed, and cannot be extracted (See [Platform-DevID-TPM-2.0]).

Keeping keys safe is a critical enabler of trustworthiness, but it’s just part of attestation security; knowing which keys are bound to the device in question is just as important in an environment where private keys are never exposed.

While there are many ways to manage keys in a TPM (see [Platform-DevID-TPM-2.0]), RIV includes support for "zero touch" provisioning (also known as zero-touch onboarding) of fielded devices (e.g., Secure ZTP, [RFC8572]), where keys which have predictable trust properties are provisioned by the device vendor.

Device identity in RIV is based on IEEE 802.1AR Device Identity (DevID). This specification provides several elements:

* A DevID requires a unique key pair for each device, accompanied by an X.509 certificate,

* The private portion of the DevID key is to be stored in the device, in a manner that provides confidentiality (Section 6.2.5 [IEEE-802-1AR])

The X.509 certificate contains several components:

* The public part of the unique DevID key assigned to that device allows a challenge of identity.

* An identifying string that’s unique to the manufacturer of the device. This is normally the serial number of the unit, which might also be printed on a label on the device.

* The certificate must be signed by a key traceable to the manufacturer’s root key.

With these elements, the device’s manufacturer and serial number can be identified by analyzing the DevID certificate plus the chain of intermediate certificates leading back to the manufacturer’s root certificate. As is conventional in TLS or SSH connections, a random nonce must be signed by the device in response to a challenge, proving possession of its DevID private key.
RIV uses the DevID to validate a TLS or SSH connection to the device as the attestation session begins. Security of this process derives from TLS or SSH security, with the DevID, containing a device serial number, providing proof that the session terminates on the intended device. See [RFC8446], [RFC4253].

Evidence of software integrity is delivered in the form of a quote signed by the TPM itself, accompanied by an IAK certificate containing the same identity information as the DevID. Because the contents of the quote are signed inside the TPM, any external modification (including reformatting to a different data format) after measurements have been taken will be detected as tampering. An unbroken chain of trust is essential to ensuring that blocks of code that are taking measurements have been verified before execution (see Figure 1).

Requiring measurements of the operating software to be signed by a key known only to the TPM also removes the need to trust the device’s operating software (beyond the first measurement in the RTM; see below); any changes to the quote, generated and signed by the TPM itself, made by malicious device software, or in the path back to the Verifier, will invalidate the signature on the quote.

A critical feature of the YANG model described in [I-D.ietf-rats-yang-tpm-charra] is the ability to carry TPM data structures in their TCG-defined format, without requiring any changes to the structures as they were signed and delivered by the TPM. While alternate methods of conveying TPM quotes could compress out redundant information, or add another layer of signing using external keys, the implementation MUST preserve the TPM signing, so that tampering anywhere in the path between the TPM itself and the Verifier can be detected.

5.2. Prevention of Spoofing and Person-in-the-Middle Attacks

Prevention of spoofing attacks against attestation systems is also important. There are several cases to consider:

* The entire device could be spoofed. If the Verifier goes to appraise a specific Attester, it might be redirected to a different Attester.

* A compromised device could have a valid DevID, but substitute a quote from a known-good device, instead of returning its own, as described in [RFC6813].

* A device with a compromised OS could return a fabricated quote providing spoofed attestation Evidence.
Use of the 802.1AR Device Identity (DevID) in the TPM provides protection against the case of a spoofed device, by ensuring that the Verifier’s TLS or SSH session is in fact terminating on the right device.

Protection against spoofed quotes from a device with valid identity is a bit more complex. An identity key must be available to sign any kind of nonce or hash offered by the Verifier, and consequently, could be used to sign a fabricated quote. To block a spoofed Attestation Result, the quote generated inside the TPM must be signed by a key that’s different from the DevID, called an Attestation Key (AK).

Given separate Attestation and DevID keys, the binding between the AK and the same device must also be proven to prevent a person-in-the-middle attack (e.g., the ‘Asokan Attack’ [RFC6813]).

This is accomplished in RIV through use of an AK certificate with the same elements as the DevID (same manufacturer’s serial number, signed by the same manufacturer’s key), but containing the device’s unique AK public key instead of the DevID public key. This binding between DevID and AK certificates is critical to reliable attestation.

The TCG document TPM 2.0 Keys for Device Identity and Attestation [Platform-DevID-TPM-2.0] specifies OIDs for Attestation Certificates that allow the CA to mark a key as specifically known to be an Attestation key.

These two key-pairs and certificates are used together:

* The DevID is used to validate a TLS connection terminating on the device with a known serial number.

* The AK is used to sign attestation quotes, providing proof that the attestation evidence comes from the same device.

5.3. Replay Attacks

Replay attacks, where results of a previous attestation are submitted in response to subsequent requests, are usually prevented by inclusion of a random nonce in the request to the TPM for a quote. Each request from the Verifier includes a new random number (a nonce). The resulting quote signed by the TPM contains the same nonce, allowing the Verifier to determine freshness, (i.e., that the resulting quote was generated in response to the Verifier’s specific request). Time-Based Uni-directional Attestation [I-D.birkholz-rats-tuda] provides an alternate mechanism to verify freshness without requiring a request/response cycle.
5.4. Owner-Signed Keys

Although device manufacturers must pre-provision devices with easily verified DevID and AK certificates if zero-touch provisioning such as described in [RFC8572] is to be supported, use of those credentials is not mandatory. IEEE 802.1AR incorporates the idea of an Initial Device ID (IDevID), provisioned by the manufacturer, and a Local Device ID (LDevID) provisioned by the owner of the device. RIV and [Platform-DevID-TPM-2.0] extends that concept by defining an Initial Attestation Key (IAK) and Local Attestation Key (LAK) with the same properties.

Device owners can use any method to provision the Local credentials.

* TCG document [Platform-DevID-TPM-2.0] shows how the initial Attestation keys can be used to certify LDevID and LAK keys. Use of the LDevID and LAK allows the device owner to use a uniform identity structure across device types from multiple manufacturers (in the same way that an "Asset Tag" is used by many enterprises to identify devices they own). TCG document [Provisioning-TPM-2.0] also contains guidance on provisioning Local identity keys in TPM 2.0. Owners should follow the same practice of binding Local DevID and Local AK as the manufacturer would for IDevID and IAK. See Section Section 2.2.

* Device owners, however, can use any other mechanism they want to assure themselves that local identity certificates are inserted into the intended device, including physical inspection and programming in a secure location, if they prefer to avoid placing trust in the manufacturer-provided keys.

Clearly, local keys can’t be used for secure Zero Touch provisioning; installation of the local keys can only be done by some process that runs before the device is installed for network operation, or using procedures such as those outlined in Bootstrapping Remote Secure Key Infrastructure (BRSKI) [RFC8995].

On the other end of the device life cycle, provision should be made to wipe local keys when a device is decommissioned, to indicate that the device is no longer owned by the enterprise. The manufacturer’s Initial identity keys must be preserved, as they contain no information that’s not already printed on the device’s serial number plate.

5.5. Other Factors for Trustworthy Operation

In addition to trustworthy provisioning of keys, RIV depends on a number of other factors for trustworthy operation.
Secure identity depends on mechanisms to prevent per-device secret keys from being compromised. The TPM provides this capability as a Root of Trust for Storage.

Attestation depends on an unbroken chain of measurements, starting from the very first measurement. See Section 9.1 for background on TPM practices.

That first measurement is made by code called the Root of Trust for Measurement, typically done by trusted firmware stored in boot flash. Mechanisms for maintaining the trustworthiness of the RTM are out of scope for RIV, but could include immutable firmware, signed updates, or a vendor-specific hardware verification technique. See Section 9.2 for background on roots of trust.

The device owner SHOULD provide some level of physical defense for the device. If a TPM that has already been programmed with an authentic DevID is stolen and inserted into a counterfeit device, attestation of that counterfeit device may become indistinguishable from an authentic device.

RIV also depends on reliable Reference Values, as expressed by the RIM [RIM]. The definition of trust procedures for RIMs is out of scope for RIV, and the device owner is free to use any policy to validate a set of reference measurements. It should also be noted that, while RIV can provide a reliable indication that a known software package is in use by the device, and that the package has not been tampered, it is the device owner’s responsibility to determine that it’s the correct package for the application.

RIMs may be conveyed out-of-band or in-band, as part of the attestation process (see Section 3.1.3). But for network devices, where software is usually shipped as a self-contained package, RIMs signed by the manufacturer and delivered in-band may be more convenient for the device owner.

The validity of RIV attestation results is also influenced by procedures used to create Reference Values:

* While the RIM itself is signed, supply-chains SHOULD be carefully scrutinized to ensure that the values are not subject to unexpected manipulation prior to signing. Insider-attacks against code bases and build chains are particularly hard to spot.

* Designers SHOULD guard against hash collision attacks. Reference Integrity Manifests often give hashes for large objects of indeterminate size; if one of the measured objects can be replaced with an implant engineered to produce the same hash, RIV will be
unable to detect the substitution. TPM1.2 uses SHA-1 hashes only, which have been shown to be susceptible to collision attack. TPM2.0 will produce quotes with SHA-256, which so far has resisted such attacks. Consequently, RIV implementations SHOULD use TPM2.0.

6. IANA Considerations

This document has no IANA actions.

7. Conclusion

TCG technologies can play an important part in the implementation of Remote Integrity Verification. Standards for many of the components needed for implementation of RIV already exist:

* Platform identity can be based on IEEE 802.1AR Device Identity, coupled with careful supply-chain management by the manufacturer.

* Complex supply chains can be certified using TCG Platform Certificates [Platform-Certificates].

* The TCG TAP mechanism coupled with [I-D.ietf-rats-yang-tpm-charra] can be used to retrieve attestation evidence.

* Reference Values must be conveyed from the software authority (e.g., the manufacturer) in Reference Integrity Manifests, to the system in which verification will take place. IETF and TCG SWID and CoSWID work ([I-D.ietf-sacm-coswid], [RIM]) forms the basis for this function.

9. Appendix

9.1. Using a TPM for Attestation

The Trusted Platform Module and surrounding ecosystem provide three interlocking capabilities to enable secure collection of evidence from a remote device, Platform Configuration Registers (PCRs), a Quote mechanism, and a standardized Event Log.
Each TPM has at least eight and at most twenty-four PCRs (depending on the profile and vendor choices), each one large enough to hold one hash value (SHA-1, SHA-256, and other hash algorithms can be used, depending on TPM version). PCRs can’t be accessed directly from outside the chip, but the TPM interface provides a way to "extend" a new security measurement hash into any PCR, a process by which the existing value in the PCR is hashed with the new security measurement hash, and the result placed back into the same PCR. The result is a composite fingerprint comprising the hash of all the security measurements extended into each PCR since the system was reset.

Every time a PCR is extended, an entry should be added to the corresponding Event Log. Logs contain the security measurement hash plus informative fields offering hints as to which event generated the security measurement. The Event Log itself is protected against accidental manipulation, but it is implicitly tamper-evident - any verification process can read the security measurement hash from the log events, compute the composite value and compare that to what ended up in the PCR. If there’s no discrepancy, the logs do provide an accurate view of what was placed into the PCR.

Note that the composite hash-of-hashes recorded in PCRs is order-dependent, resulting in different PCR values for different ordering of the same set of events (e.g. Event A followed by Event B yields a different PCR value than B followed by A). For single-threaded code, where both the events and their order are fixed, a Verifier may validate a single PCR value, and use the log only to diagnose a mismatch from Reference Values. However, operating system code is usually non-deterministic, meaning that there may never be a single "known good" PCR value. In this case, the Verifier may have to verify that the log is correct, and then analyze each item in the log to determine if it represents an authorized event.

In a conventional TPM Attestation environment, the first measurement must be made and extended into the TPM by trusted device code (called the Root of Trust for Measurement, RTM). That first measurement should cover the segment of code that is run immediately after the RTM, which then measures the next code segment before running it, and so on, forming an unbroken chain of trust. See [TCGRoT] for more on Mutable vs Immutable roots of trust.

The TPM provides another mechanism called a Quote that can read the current value of the PCRs and package them, along with the Verifier’s nonce, into a TPM-specific data structure signed by an Attestation private key, known only to the TPM.
As noted above in Section 5 Security Considerations, it’s important to note that the Quote data structure is signed inside the TPM. The trust model is preserved by retrieving the Quote in a way that does not invalidate the signature, as specified in [I-D.ietf-rats-yang-tpm-charra]. The structure of the command and response for a quote, including its signature, as generated by the TPM, can be seen in [TPM1.2] Part 3, Section 16.5, and [TPM2.0] Section 18.4.2.

The Verifier uses the Quote and Log together. The Quote contains the composite hash of the complete sequence of security measurement hashes, signed by the TPM’s private Attestation Key. The Log contains a record of each measurement extended into the TPM’s PCRs. By computing the composite hash of all the measurements, the Verifier can verify the integrity of the Event Log, even though the Event Log itself is not signed. Each hash in the validated Event Log can then be compared to corresponding expected values in the set of Reference Values to validate overall system integrity.

A summary of information exchanged in obtaining quotes from TPM1.2 and TPM2.0 can be found in [TAP], Section 4. Detailed information about PCRs and Quote data structures can be found in [TPM1.2], [TPM2.0]. Recommended log formats include [PC-Client-BIOS-TPM-2.0], and [Canonical-Event-Log].

9.2. Root of Trust for Measurement

The measurements needed for attestation require that the device being attested is equipped with a Root of Trust for Measurement, that is, some trustworthy mechanism that can compute the first measurement in the chain of trust required to attest that each stage of system startup is verified, a Root of Trust for Storage (i.e., the TPM PCRs) to record the results, and a Root of Trust for Reporting to report the results.

While there are many complex aspects of Roots of Trust ([TCGroot], [SP800-155], [SP800-193]), two aspects that are important in the case of attestation are:

* The first measurement computed by the Root of Trust for Measurement, and stored in the TPM’s Root of Trust for Storage, must be assumed to be correct.

* There must not be a way to reset the Root of Trust for Storage without re-entering the Root of Trust for Measurement code.
The first measurement must be computed by code that is implicitly trusted; if that first measurement can be subverted, none of the remaining measurements can be trusted. (See [SP800-155])

It’s important to note that the trustworthiness of the RTM code cannot be assured by the TPM or TPM supplier - code or procedures external to the TPM must guarantee the security of the RTM.

9.3. Layering Model for Network Equipment Attester and Verifier

Retrieval of identity and attestation state uses one protocol stack, while retrieval of Reference Values uses a different set of protocols. Figure 5 shows the components involved.
Figure 6: RIV Protocol Stacks

IETF documents are captured in boxes surrounded by asterisks. TCG documents are shown in boxes surrounded by dots.
9.4. Implementation Notes

Figure 7 summarizes many of the actions needed to complete an Attestation system, with links to relevant documents. While documents are controlled by several standards organizations, the implied actions required for implementation are all the responsibility of the manufacturer of the device, unless otherwise noted.

As noted, SWID tags can be generated many ways, but one possible tool is [SWID-Gen]

| o Attestation depends on a secure root of trust for measurement outside the TPM, as well as roots for storage and reporting inside the TPM. 
  o Refer to TCG Root of Trust for Measurement. 
  o NIST SP 800-193 also provides guidelines on Roots of Trust | |
| Provision the TPM as described in [Platform-DevID-TPM-2.0] TCG documents. | TCG Platform Certificate |
| Put a DevID or Platform Cert in the TPM | TCG TPM DevID TCG Platform Certificate IEEE 802.1AR |
| o Install an Initial Attestation Key at the same time so that Attestation can work out of the box 
  o Equipment suppliers and owners may want to implement Local Device ID as well as Initial Device ID | |
| Connect the TPM to the TLS stack | Vendor TLS stack (This action is configuring TLS to use the DevID as its client certificate) |
| o Use the DevID in the TPM to authenticate TAP connections, identifying the device | |
| Make CoSWID tags for BIOS/Loader/Kernel objects | IETF CoSWID ISO/IEC 19770-2 NIST IR 8060 |
| o Add reference measurements into SWID tags 
  o Manufacturer should sign the SWID tags | |
The TCG RIM-IM identifies further procedures to create signed RIM documents that provide the necessary reference information.

Package the SWID tags with a vendor software release
- A tag-generator plugin such as [SWID-Gen] can be used

Use PC Client measurement definitions to define the use of PCRs (although Windows OS is rare on Networking Equipment, UEFI BIOS is not)

Use TAP to retrieve measurements
- Map to YANG
- Use Canonical Log Format

Posture Collection Server (as described in IETF SACMs ECP) should request the attestation and analyze the result.

The Management application might be broken down to several more components:
- A Posture Manager Server which collects reports and stores them in a database
- One or more Analyzers that can look at the results and figure out what it means.

A CBOR Tag for Unprotected CWT Claims Sets
draft-ietf-rats-uccs-02

Abstract

CBOR Web Token (CWT, RFC 8392) Claims Sets sometimes do not need the protection afforded by wrapping them into COSE, as is required for a true CWT. This specification defines a CBOR tag for such unprotected CWT Claims Sets (UCCS) and discusses conditions for its proper use.

// The present version (-01) has a few editorial improvements over // -00 and attempts to address points from Thomas Fossati’s // 2021-03-16 review, for further discussion at IETF 111.

About This Document

This note is to be removed before publishing as an RFC.

Status information for this document may be found at https://datatracker.ietf.org/doc/draft-ietf-rats-uccs/.

Discussion of this document takes place on the Remote ATtestation ProcedureS (rats) Working Group mailing list (mailto:rats@ietf.org), which is archived at https://mailarchive.ietf.org/arch/browse/rats/.

Source for this draft and an issue tracker can be found at https://github.com/ietf-rats-wg/draft-ietf-rats-uccs.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.
1. Introduction

A CBOR Web Token (CWT) as specified by [RFC8392] is always wrapped in a CBOR Object Signing and Encryption (COSE, [RFC8152]) envelope. COSE provides -- amongst other things -- the end-to-end data origin authentication and integrity protection employed by RFC 8392 and optional encryption for CWTs. Under the right circumstances (Section 3), though, a signature providing proof for authenticity and integrity can be provided through the transfer protocol and thus omitted from the information in a CWT without compromising the intended goal of authenticity and integrity. In other words, if communicating parties have a pre-existing security association they can reuse it to provide authenticity and integrity for their messages, enabling the basic principle of using resources parsimoniously. Specifically, if a mutually Secured Channel is established between two remote peers, and if that Secure Channel provides the required properties (as discussed below), it is possible to omit the protection provided by COSE, creating a use case for unprotected CWT Claims Sets. Similarly, if there is one-way authentication, the party that did not authenticate may be in a position to send authentication information through this channel that allows the already authenticated party to authenticate the other party.

This specification allocates a CBOR tag to mark Unprotected CWT Claims Sets (UCCS) as such and discusses conditions for its proper use in the scope of Remote ATtestation procedureS (RATS) and the conveyance of Evidence from an Attester to a Verifier.

This specification does not change [RFC8392]: A true CWT does not make use of the tag allocated here; the UCCS tag is an alternative to using COSE protection and a CWT tag. Consequently, within the well-defined scope of a secured channel, it can be acceptable and economic to use the contents of a CWT without its COSE container and tag it with a UCCS CBOR tag for further processing within that scope -- or to use the contents of a UCCS CBOR tag for building a CWT to be signed by some entity that can vouch for those contents.

1.1. Terminology

The term Claim is used as in [RFC7519].

The terms Claim Key, Claim Value, and CWT Claims Set are used as in [RFC8392].

The terms Attester, Attesting Environment and Verifier are used as in [I-D.ietf-rats-architecture].
UCCS: Unprotected CWT Claims Set(s); CBOR map(s) of Claims as defined by the CWT Claims Registry that are composed of pairs of Claim Keys and Claim Values.

Secure Channel: A protected communication channel between two peers that can ensure the same qualities associated for UCCS conveyance as CWT conveyance without any additional protection.

All terms referenced or defined in this section are capitalized in the remainder of this document.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

2. Example Use Cases

Use cases involving the conveyance of Claims, in particular, remote attestation procedures (RATS, see [I-D.ietf-rats-architecture]) require a standardized data definition and encoding format that can be transferred and transported using different communication channels. As these are Claims, [RFC8392] is a suitable format. However, the way these Claims are secured depends on the deployment, the security capabilities of the device, as well as their software stack. For example, a Claim may be securely stored and conveyed using a device’s Trusted Execution Environment (TEE, see [I-D.ietf-teep-architecture]) or especially in some resource constrained environments, the same process that provides the secure communication transport is also the delegate to compose the Claim to be conveyed. Whether it is a transfer or transport, a Secure Channel is presumed to be used for conveying such UCCS. The following sections further describe the RATS usage scenario and corresponding requirements for UCCS deployment.

3. Characteristics of a Secure Channel

A Secure Channel for the conveyance of UCCS needs to provide the security properties that would otherwise be provided by COSE for a CWT. In this regard, UCCS is similar in security considerations to JWTs [RFC8725] using the algorithm "none". RFC 8725 states:

| [...] if a JWT is cryptographically protected end-to-end by a transport layer, such as TLS using cryptographically current algorithms, there may be no need to apply another layer of cryptographic protections to the JWT. In such cases, the use of the "none" algorithm can be perfectly acceptable. |
The security considerations discussed, e.g., in Sections 2.1, 3.1, and 3.2 of [RFC8725] apply in an analogous way to the use of UCCS as elaborated on in this document.

Secure Channels are often set up in a handshake protocol that mutually derives a session key, where the handshake protocol establishes the (identity and thus) authenticity of one or both ends of the communication. The session key can then be used to provide confidentiality and integrity of the transfer of information inside the Secure Channel. A well-known example of a such a Secure Channel setup protocol is the TLS [RFC8446] handshake; the TLS record protocol can then be used for secure conveyance.

As UCCS were initially created for use in Remote ATtestation procedureS (RATS) Secure Channels, the following subsection provides a discussion of their use in these channels. Where other environments are intended to be used to convey UCCS, similar considerations need to be documented before UCCS can be used.

3.1. UCCS and Remote ATtestation procedureS (RATS)

For the purposes of this section, the Verifier is the receiver of the UCCS and the Attester is the provider of the UCCS.

Secure Channels can be transient in nature. For the purposes of this specification, the mechanisms used to establish a Secure Channel are out of scope.

As a minimum requirement in the scope of RATS Claims, the Verifier MUST authenticate the Attester as part of the establishment of the Secure Channel. Furthermore, the channel MUST provide integrity of the communication from the Attester to the Verifier. If confidentiality is also required, the receiving side needs to be authenticated as well; this can be achieved if the Verifier and the Attester mutually authenticate when establishing the Secure Channel.

The extent to which a Secure Channel can provide assurances that UCCS originate from a trustworthy attesting environment depends on the characteristics of both the cryptographic mechanisms used to establish the channel and the characteristics of the attesting environment itself.

A Secure Channel established or maintained using weak cryptography may not provide the assurance required by a relying party of the authenticity and integrity of the UCCS.
Ultimately, it is up to the Verifier’s policy to determine whether to accept a UCCS from the Attester and to the type of Secure Channel it must negotiate. While the security considerations of the cryptographic algorithms used are similar to COSE, the considerations of the secure channel should also adhere to the policy configured at each of the Attester and the Verifier. However, the policy controls and definitions are out of scope for this document.

Where the security assurance required of an attesting environment by a relying party requires it, the attesting environment may be implemented using techniques designed to provide enhanced protection from an attacker wishing to tamper with or forge UCCS. A possible approach might be to implement the attesting environment in a hardened environment such as a TEE [I-D.ietf-teep-architecture] or a TPM [TPM2].

When UCCS emerge from the Secure Channel and into the Verifier, the security properties of the Secure Channel no longer apply and UCCS have the same properties as any other unprotected data in the Verifier environment. If the Verifier subsequently forwards UCCS, they are treated as though they originated within the Verifier.

As with EATs nested in other EATs (Section 3.20.1.2 of [I-D.ietf-rats-eat]), the Secure Channel does not endorse fully formed CWTs transferred through it. Effectively, the COSE envelope of a CWT shields the CWT Claims Set from the endorsement of the Secure Channel. (Note that EAT might add a nested UCCS Claim, and this statement does not apply to UCCS nested into UCCS, only to fully formed CWTs)

3.2. Privacy Preserving Channels

A Secure Channel which preserves the privacy of the Attester may provide security properties equivalent to COSE, but only inside the life-span of the session established. In general, a Verifier cannot correlate UCCS received in different sessions from the same attesting environment based on the cryptographic mechanisms used when a privacy preserving Secure Channel is employed.
In the case of a Remote Attestation, the attester must consider whether any UCCS it returns over a privacy preserving Secure Channel compromises the privacy in unacceptable ways. As an example, the use of the EAT UEID [I-D.ietf-rats-eat] Claim in UCCS over a privacy preserving Secure Channel allows a verifier to correlate UCCS from a single attesting environment across many Secure Channel sessions. This may be acceptable in some use-cases (e.g. if the attesting environment is a physical sensor in a factory) and unacceptable in others (e.g. if the attesting environment is a device belonging to a child).

4. IANA Considerations

In the registry [IANA.cbor-tags], IANA is requested to allocate the tag in Table 1 from the FCFS space, with the present document as the specification reference.

<table>
<thead>
<tr>
<th>Tag</th>
<th>Data Item</th>
<th>Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>TBD601</td>
<td>map</td>
<td>Unprotected CWT Claims Set [RFCthis]</td>
</tr>
</tbody>
</table>

Table 1: Values for Tags

5. Security Considerations

The security considerations of [RFC8949] apply. The security considerations of [RFC8392] need to be applied analogously, replacing the role of COSE with that of the Secured Channel.

Section 3 discusses security considerations for Secure Channels, in which UCCS might be used. This document provides the CBOR tag definition for UCCS and a discussion on security consideration for the use of UCCS in Remote Attestation procedures (RATS). Uses of UCCS outside the scope of RATS are not covered by this document. The UCCS specification - and the use of the UCCS CBOR tag, correspondingly - is not intended for use in a scope where a scope-specific security consideration discussion has not been conducted, vetted and approved for that use.

5.1. General Considerations

Implementations of Secure Channels are often separate from the application logic that has security requirements on them. Similar security considerations to those described in [I-D.ietf-cose-rfc8152bis-struct] for obtaining the required levels of assurance include:
Implementations need to provide sufficient protection for private or secret key material used to establish or protect the Secure Channel.

Using a key for more than one algorithm can leak information about the key and is not recommended.

An algorithm used to establish or protect the Secure Channel may have limits on the number of times that a key can be used without leaking information about the key.

The Verifier needs to ensure that the management of key material used to establish or protect the Secure Channel is acceptable. This may include factors such as:

- Ensuring that any permissions associated with key ownership are respected in the establishment of the Secure Channel.
- Cryptographic algorithms are used appropriately.
- Key material is used in accordance with any usage restrictions such as freshness or algorithm restrictions.
- Ensuring that appropriate protections are in place to address potential traffic analysis attacks.

5.2. AES-CBC_MAC

- A given key should only be used for messages of fixed or known length.
- Different keys should be used for authentication and encryption operations.
- A mechanism to ensure that IV cannot be modified is required.

Section 3.2.1 of [I-D.ietf-cose-rfc8152bis-algs] contains a detailed explanation of these considerations.

5.3. AES-GCM

- The key and nonce pair are unique for every encrypted message.
- The maximum number of messages to be encrypted for a given key is not exceeded.

Section 4.1.1 of [I-D.ietf-cose-rfc8152bis-algs] contains a detailed explanation of these considerations.
5.4. AES-CCM

* The key and nonce pair are unique for every encrypted message.
* The maximum number of messages to be encrypted for a given block cipher is not exceeded.
* The number of messages both successfully and unsuccessfully decrypted is used to determine when rekeying is required.

Section 4.2.1 of [I-D.ietf-cose-rfc8152bis-algs] contains a detailed explanation of these considerations.

5.5. ChaCha20 and Poly1305

* The nonce is unique for every encrypted message.
* The number of messages both successfully and unsuccessfully decrypted is used to determine when rekeying is required.

Section 4.3.1 of [I-D.ietf-cose-rfc8152bis-algs] contains a detailed explanation of these considerations.

Appendix A. CDDL

[RFC8392] does not define CDDL for CWT Claims sets.

This specification proposes using the definitions in Figure 1 for the claims set defined in [RFC8392]. Note that these definitions have been built such that they also can describe [RFC7519] claims sets by disabling feature "cbor" and enabling feature "json", but this flexibility is not the subject of the present specification.
Claims-Set = {
  * $$Claims-Set-Claims
    * Claim-Label .feature "extended-claims-label" => any
}  
Claim-Label = int / text
string-or-uri = text

$$Claims-Set-Claims //= ( iss-claim-label => string-or-uri )
$$Claims-Set-Claims //= ( sub-claim-label => string-or-uri )
$$Claims-Set-Claims //= ( aud-claim-label => string-or-uri )
$$Claims-Set-Claims //= ( exp-claim-label => ˜time )
$$Claims-Set-Claims //= ( nbf-claim-label => ˜time )
$$Claims-Set-Claims //= ( iat-claim-label => ˜time )
$$Claims-Set-Claims //= ( cti-claim-label => bytes )

iss-claim-label = JC<"iss", 1>
sub-claim-label = JC<"sub", 2>
aud-claim-label = JC<"aud", 3>
exp-claim-label = JC<"exp", 4>
nbf-claim-label = JC<"nbf", 5>
iat-claim-label = JC<"iat", 6>
cti-claim-label = CBOR-ONLY<7> ; jti in JWT: different name and text

JSON-ONLY<J> = J .feature "json"
CBOR-ONLY<C> = C .feature "cbor"
JC<J,C> = JSON-ONLY<J> / CBOR-ONLY<C>

Figure 1: CDDL definition for Claims-Set

Specifications that define additional claims should also supply additions to the $$Claims-Set-Claims socket, e.g.:
$$Claims-Set-Claims //= (8: CWT-cnf) ; cnf
CWT-cnf = {
  (1: CWT-COSE-Key) //
  (2: CWT-Encrypted_COSE_Key) //
  (3: CWT-kid)
}

CWT-COSE-Key = COSE_Key
CWT-Encrypted_COSE_Key = COSE_Encrypt / COSE_Encrypt0
CWT-kid = bytes

$$Claims-Set-Claims //= (9: CWT-scope) ; scope
; TO DO: understand what this means:
; scope The scope of an access token as defined in RFC6749.
; scope 9 byte string or text string [IESG] [RFC8693, Section 4.2]
CWT-scope = bytes / text

; [RFC8693]
$$Claims-Set-Claims //= (38: CWT-ace-profile) ; ace_profile
CWT-ace-profile = $CWT-ACE-Profiles /
  int . feature "ace_profile-extend"
; fill in from IANA registry
; https://www.iana.org/assignments/ace/ace.xhtml#ace-profiles :
$CWT-ACE-Profiles /= 1 ; coap_dtls

$$Claims-Set-Claims //= (39: CWT-cnonce) ; cnonce
CWT-cnonce = bytes

$$Claims-Set-Claims //= (40: CWT-exi) ; exi
CWT-exi = uint ; in seconds (5.10.3)

;;; insert CDDL from 9052-to-be to complete these CDDL definitions.

Appendix B. Example

The example CWT Claims Set from Appendix A.1 of RFC8392 can be
turned into an UCCS by enclosing it with a tag number TBD601:
<TBD601>(
  {
    /iss/1: "coap://as.example.com",
    /sub/2: "erikw",
    /aud/3: "coap://light.example.com",
    /exp/4: 1444064944,
    /nbf/5: 1443944944,
    /iat/6: 1443944944,
    /cti/7: h’0b71’
  }
)

A YANG Data Model for Challenge-Response-based Remote Attestation
Procedures using TPMs
draft-ietf-rats-yang-tpm-charra-21

Abstract

This document defines YANG RPCs and a few configuration nodes required to retrieve attestation evidence about integrity measurements from a device, following the operational context defined in TPM-based Network Device Remote Integrity Verification. Complementary measurement logs are also provided by the YANG RPCs, originating from one or more roots of trust for measurement (RTMs). The module defined requires at least one TPM 1.2 or TPM 2.0 as well as a corresponding TPM Software Stack (TSS), or equivalent hardware implementations that include the protected capabilities as provided by TPMs as well as a corresponding software stack, included in the device components of the composite device the YANG server is running on.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.
1. Introduction

This document is based on the general terminology defined in [I-D.ietf-rats-architecture] and uses the operational context defined in [I-D.ietf-rats-tpm-based-network-device-attest] as well as the interaction model and information elements defined in [I-D.ietf-rats-reference-interaction-models]. The currently supported hardware security modules (HSMs) are the Trusted Platform Modules (TPMs) [TPM1.2] and [TPM2.0] as specified by the Trusted Computing Group (TCG). One TPM, or multiple TPMs in the case of a
Composite Device, are required in order to use the YANG module defined in this document. Each TPM is used as a root of trust for storage (RTS) in order to store system security measurement Evidence. And each TPM is used as a root of trust for reporting (RTR) in order to retrieve attestation Evidence. This is done by using a YANG RPC to request a quote which exposes a rolling hash of the security measurements held internally within the TPM.

Specific terms imported from [I-D.ietf-rats-architecture] and used in this document include: Attester, Composite Device, Evidence.

Specific terms imported from [TPM2.0-Key] and used in this document include: Endorsement Key (EK), Initial Attestation Key (IAK), Attestation Identity Key (AIK), Local Attestation Key (LAK).

1.1. Requirements notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

2. The YANG Module for Basic Remote Attestation Procedures

One or more TPMs MUST be embedded in a Composite Device that provides attestation evidence via the YANG module defined in this document. The ietf-tpm-remote-attestation YANG module enables a composite device to take on the role of an Attester, in accordance with the Remote Attestation Procedures (RATS) architecture [I-D.ietf-rats-architecture], and the corresponding challenge-response interaction model defined in the [I-D.ietf-rats-reference-interaction-models] document. A fresh nonce with an appropriate amount of entropy [NIST-915121] MUST be supplied by the YANG client in order to enable a proof-of-freshness with respect to the attestation Evidence provided by the Attester running the YANG datastore. Further, this nonce is used to prevent replay attacks. The method for communicating the relationship of each individual TPM to specific measured component within the Composite Device is out of the scope of this document.

2.1. YANG Modules

In this section the several YANG modules are defined.
2.1.1. ‘ietf-tpm-remote-attestation’

This YANG module imports modules from [RFC6991] with prefix ‘yang’, [RFC8348] with prefix ‘hw’, [I-D.ietf-netconf-keystore] with prefix ‘ks’, and ‘ietf-tpg-algs.yang’ Section 2.1.2.3 with prefix ‘taa’. Additionally, references are made to [RFC8032], [RFC8017], [RFC6933], [TPM1.2-Commands], [TPM2.0-Arch], [TPM2.0-Structures], [TPM2.0-Key], [TPM1.2-Structures], [bios-log], [BIOS-Log-Event-Type], as well as Appendix A and Appendix B.

2.1.1.1. Features

This module supports the following features:

* ‘mtpm’: Indicates that multiple TPMs on the device can support remote attestation. For example, this feature could be used in cases where multiple line cards are present, each with its own TPM.

* ‘bios’: Indicates that the device supports the retrieval of BIOS/UEFI event logs. [bios-log]

* ‘ima’: Indicates that the device supports the retrieval of event logs from the Linux Integrity Measurement Architecture (IMA, see Appendix A).

* ‘neteqqip_boot’: Indicates that the device supports the retrieval of neteqqip boot event logs. See Appendix A and Appendix B.

2.1.1.2. Identities

This module supports the following types of attestation event logs: ‘bios’, ‘ima’, and ‘neteqqip_boot’.

2.1.1.3. Remote Procedure Calls (RPCs)

In the following, RPCs for both TPM 1.2 and TPM 2.0 attestation procedures are defined.

2.1.1.3.1. ‘tpm12-challenge-response-attestation’

This RPC allows a Verifier to request signed TPM PCRs (TPM Quote operation) from a TPM 1.2 compliant cryptoprocessor. Where the feature ‘mtpm’ is active, and one or more ‘certificate-name’ is not provided, all TPM 1.2 compliant cryptoprocessors will respond. A YANG tree diagram of this RPC is as follows:
2.1.1.3.2. ‘tpm20-challenge-response-attestation’

This RPC allows a Verifier to request signed TPM PCRs (_TPM Quote_ operation) from a TPM 2.0 compliant cryptoprocessor. Where the feature ‘mtpm’ is active, and one or more ‘certificate-name’ is not provided, all TPM 2.0 compliant cryptoprocessors will respond. A YANG tree diagram of this RPC is as follows:

An example of an RPC challenge requesting PCRs 0-7 from a SHA-256 bank could look like the following:
<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <tpm20-challenge-response-attestation>
    <certificate-name>
      (identifier of a TPM signature key with which the Verifier is supposed to sign the attestation data)
    </certificate-name>
    <nonce>
      0xe041307208d9f78f5b1bbecd19e2d152ad49de2fc5a7d8dbf769f6b8ffdeab9
    </nonce>
    <tpm20-pcr-selection>
      <tpm20-hash-algo
        xmlns="urn:ietf:params:xml:ns:yang:ietf-tcg-algs">
        TPM_ALG_SHA256
      </tpm20-hash-algo>
      <pcr-index>0</pcr-index>
      <pcr-index>1</pcr-index>
      <pcr-index>2</pcr-index>
      <pcr-index>3</pcr-index>
      <pcr-index>4</pcr-index>
      <pcr-index>5</pcr-index>
      <pcr-index>6</pcr-index>
      <pcr-index>7</pcr-index>
    </tpm20-pcr-selection>
  </tpm20-challenge-response-attestation>
</rpc>

A successful response could be formatted as follows:

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <tpm20-attestation-response
    xmlns="urn:ietf:params:xml:ns:yang:ietf-tpm-remote-attestation">
    <certificate-name
      xmlns="urn:ietf:params:xml:ns:yang:ietf-keystore">
      (instance of Certificate name in the Keystore)
    </certificate-name>
    <attestation-data>
      (raw attestation data, i.e. the TPM quote; this includes a composite digest of requested PCRs, the nonce, and TPM 2.0 time information.)
    </attestation-data>
    <quote-signature>
      (signature over attestation-data using the TPM key identified by sig-key-id)
    </quote-signature>
  </tpm20-attestation-response>
</rpc-reply>
2.1.1.4. ’log-retrieval’

This RPC allows a Verifier to acquire the evidence which was extended into specific TPM PCRs. A YANG tree diagram of this RPC is as follows:

```
+---x log-retrieval
   +---w input
      |   +---w log-type identityref
      |   +---w log-selector* []
      |       +---w name* string
      |       +---w (index-type)?
      |           +--:(last-entry)
      |               |   +---w last-entry-value? binary
      |               +--:(index)
      |                   +---w last-index-number? uint64
      |                   +--:(timestamp)
      |                       +---w timestamp? yang:date-and-time
      +---w log-entry-quantity? uint16
   +--ro output
      +---ro system-event-logs
      +---ro node-data* []
      |   +---ro name? string
      |   +---ro up-time? uint32
      +---ro log-result
      |   +---:(attested_event_log_type)
      |       +--:(bios) (bios)?
      |           +---ro bios-event-logs
      |               +---ro bios-event-entry* [event-number]
      |                   +---ro event-number uint32
      |                   +---ro event-type? uint32
      |                   +---ro pcr-index? pcr
      |                   +---ro digest-list* []
      |                       +---ro hash-algo? identityref
      |                       +---ro digest* binary
      |               +---ro event-size? uint32
      |               +---ro event-data* binary
      +--:(ima) (ima)?
      +---ro ima-event-logs
      |   +---ro ima-event-entry* [event-number]

```
2.1.1.5. Data Nodes

This section provides a high level description of the data nodes containing the configuration and operational objects with the YANG model. For more details, please see the YANG model itself in Figure 1.

Container ‘rats-support-structures’: This houses the set of information relating to remote attestation for a device. This includes specific device TPM(s), the compute nodes (such as line cards) on which the TPM(s) reside, and the algorithms supported across the platform.

Container ‘tpms’: Provides configuration and operational details for each supported TPM, including the tpm-firmware-version, PCRs which may be quoted, certificates which are associated with that TPM, and the current operational status. Of note are the certificates which are associated with that TPM. As a certificate is associated with a particular TPM attestation key, knowledge of the certificate allows a specific TPM to be identified.
++-rw tpms
  ++-rw tpm* [name]
    +++-rw name string
    +++-ro hardware-based boolean
    +++-ro physical-index? int32 {hw:entity-mib}?
    +++-ro path? string
    +++-rw compute-node compute-node-ref {tpm:mtpm}?
    +++-ro manufacturer? string
    +++-rw tpm12-hash-algo? identityref {taa:tpm12}?
    ++-rw tpm12-pcrs* pcr
    |  ++-rw tpm20-pcr-bank* [tpm20-hash-algo] {taa:tpm20}?
    |    |  +++-rw tpm20-hash-algo identityref
    |    |  +++-rw pcr-index* tpm:pcr
    |  +++-ro status enumeration
    ++-rw certificates
    |  ++-rw certificate* [name]
    |    +++-rw name string
    |    +++-rw keystore-ref? leafref {ks:asymmetric-keys}?
    |    +++-rw type? enumeration

container 'attester-supported-algos' - Identifies which TCG hash algorithms are available for use on the Attesting platform. An operator will use this information to limit algorithms available for use by RPCs to just a desired set from the universe of all allowed hash algorithms by the TCG.

  ++-rw attester-supported-algos
    ++-rw tpm12-asymmetric-signing* identityref {taa:tpm12}?
    ++-rw tpm12-hash* identityref {taa:tpm12}?
    +++-rw tpm20-asymmetric-signing* identityref {taa:tpm20}?
    +++-rw tpm20-hash* identityref {taa:tpm20}?

container 'compute-nodes' - When there is more than one TPM supported, this container maintains the set of information related to the compute node associated with a specific TPM. This allows each specific TPM to identify to which 'compute-node' it belongs.

  ++-rw compute-nodes {tpm:mtpm}?
    ++-ro compute-node* [node-id]
    |  +++-ro node-id string
    |  +++-ro node-physical-index? int32 {hw:entity-mib}?
    |  +++-ro node-name? string
    |  +++-ro node-location? string

"PCR values in each PCR bank. This might appear redundant with the TPM2B_DIGEST, but that digest is calculated across multiple PCRs. Having to verify across multiple PCRs does not necessarily make it easy for a Verifier to appraise just the minimum set of PCR information which has changed since the last received TPM2B_DIGEST. Put another way, why should a Verifier reconstruct the proper value of all PCR Quotes when only a single PCR has changed? To help this happen, if the Attester does know specific PCR values, the Attester can provide these individual values via 'unsigned-pcr-values'. By comparing this information to what has previously been validated, it is possible for a Verifier to confirm the Attester's signature while eliminating significant processing. Note that there should never be a result where an unsigned PCR value differs from what may be reconstructed from the within the PCR quote and the event logs. If there is a difference, a signed result which has been verified from retrieved logs is considered definitive."

2.1.2. 'ietf-tcg-algs'

This document has encoded the TCG Algorithm definitions of [TCG-Algos], revision 1.32. By including this full table as a separate YANG file within this document, it is possible for other YANG models to leverage the contents of this model. Specific references to [RFC2104], [RFC8017], [ISO-IEC-9797-1], [ISO-IEC-9797-2], [ISO-IEC-10116], [ISO-IEC-10118-3], [ISO-IEC-14888-3], [ISO-IEC-15946-1], [ISO-IEC-18033-3], [IEEE-Std-1363-2000], [IEEE-Std-1363a-2004], [NIST-PUB-FIPS-202], [NIST-SP800-38C], [NIST-SP800-38D], [NIST-SP800-38F], [NIST-SP800-56A], [NIST-SP800-108], [bios-log], as well as Appendix A and Appendix B exist within the YANG Model.

2.1.2.1. Features

There are two types of features supported: 'TPM12' and 'TPM20'. Support for either of these features indicates that a cryptoprocessor supporting the corresponding type of TCG TPM API is present on an Attester. Most commonly, only one type of cryptoprocessor will be available on an Attester.

2.1.2.2. Identities

There are three types of identities in this model:

1. Cryptographic functions supported by a TPM algorithm; these include: 'asymmetric', 'symmetric', 'hash', 'signing', 'anonymous_signing', 'encryption_mode', 'method', and 'object_type'. The definitions of each of these are in Table 2 of [TCG-Algos].

2. API specifications for TPM types: 'tpm12' and 'tpm20'

3. Specific algorithm types: Each algorithm type defines what cryptographic functions may be supported, and on which type of API specification. It is not required that an implementation of a specific TPM will support all algorithm types. The contents of each specific algorithm mirrors what is in Table 3 of [TCG-Algos].
2.1.2.3. YANG Module

<CODE BEGINS> file "ietf-tcg-algs@2022-03-23.yang"
module ietf-tcg-algs {
    yang-version 1.1;
    namespace "urn:ietf:params:xml:ns:yang:ietf-tcg-algs";

<CODE ENDS>

Note that not all cryptographic functions are required for use by
ietf-tpm-remote-attestation.yang. However the full definition of
Table 3 of [TCG-Algos] will allow use by additional YANG
specifications.

3. IANA Considerations

This document registers the following namespace URIs in the
[xml-registry] as per [RFC3688]:

4. Security Considerations

The YANG module ietf-tpm-remote-attestation.yang specified in this document defines a schema for data that is designed to be accessed via network management protocols such as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF layer is the secure transport layer, and the mandatory-to-implement secure transport is Secure Shell (SSH) [RFC6242]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [RFC8446].

There are a number of data nodes defined in this YANG module that are writable/creatable/deletable (i.e., _config true_, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., _edit-config_) to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes as well as their sensitivity/vulnerability:
Container '/rats-support-structures/attester-supported-algos': 'tpm12-asymmetric-signing', 'tpm12-hash', 'tpm20-asymmetric-signing', and 'tpm20-hash'. All could be populated with algorithms that are not supported by the underlying physical TPM installed by the equipment vendor. A vendor should restrict the ability to configure unsupported algorithms.

Container: '/rats-support-structures/tpms': 'name': Although shown as 'rw', it is system generated. Therefore, it should not be possible for an operator to add or remove a TPM from the configuration.

'tpm20-pcr-bank': It is possible to configure PCRs for extraction which are not being extended by system software. This could unnecessarily use TPM resources.

certificates': It is possible to provision a certificate which does not correspond to an Attestation Identity Key (AIK) within the TPM 1.2, or an Attestation Key (AK) within the TPM 2.0 respectively. In such a case, calls to an RPC requesting this specific certificate could result in either no response or a response for an unexpected TPM.

RPC 'tpm12-challenge-response-attestation': The receiver of the RPC response must verify that the certificate is for an active AIK, i.e., the certificate has been confirmed by a third party as being able to support Attestation on the targeted TPM 1.2.

RPC 'tpm20-challenge-response-attestation': The receiver of the RPC response must verify that the certificate is for an active AK, i.e., the private key confirmation of the quote signature within the RPC response has been confirmed by a third party to belong to an entity legitimately able to perform Attestation on the targeted TPM 2.0.

RPC 'log-retrieval': Requesting a large volume of logs from the attester could require significant system resources and create a denial of service.

Information collected through the RPCs above could reveal that specific versions of software and configurations of endpoints that could identify vulnerabilities on those systems. Therefore, RPCs should be protected by NACM [RFC8341] with a default setting of deny-all to limit the extraction of attestation data by only authorized Verifiers.
For the YANG module ietf-tcg-algs.yang, please use care when selecting specific algorithms. The introductory section of [TCG-Algos] highlights that some algorithms should be considered legacy, and recommends implementers and adopters diligently evaluate available information such as governmental, industrial, and academic research before selecting an algorithm for use.

Appendix A. Integrity Measurement Architecture (IMA)

IMA extends the principles of Measured Boot [TPM2.0-Arch] and Secure Boot [UEFI-Secure-Boot] to the Linux operating system, applying it to operating system applications and files. IMA has been part of the Linux integrity subsystem of the Linux kernel since 2009 (kernel version 2.6.30). The IMA mechanism represented by the YANG module in this specification is rooted in the kernel version 5.16 [IMA-Kernel-Source]. IMA enables the protection of system integrity by collecting (commonly referred to as measuring) and storing measurements (called Claims in the context of IETF RATS) of files before execution so that these measurements can be used later, at
system runtime, in remote attestation procedures. IMA acts in support of the appraisal of Evidence (which includes measurement Claims) by leveraging reference integrity measurements stored in extended file attributes.

In support of the appraisal of Evidence, IMA maintains an ordered list of measurements in kernel-space, the Stored Measurement Log (SML), for all files that have been measured before execution since the operating system was started. Although IMA can be used without a TPM, it is typically used in conjunction with a TPM to anchor the integrity of the SML in a hardware-protected secure storage location, i.e., Platform Configuration Registers (PCRs) provided by TPMs. IMA provides the SML in both binary and ASCII representations in the Linux security file system _securityfs_ (/sys/kernel/security/ima/).

IMA templates define the format of the SML, i.e., which fields are included in a log record. Examples are file path, file hash, user ID, group ID, file signature, and extended file attributes. IMA comes with a set of predefined template formats and also allows a custom format, i.e., a format consisting of template fields supported by IMA. Template usage is typically determined by boot arguments passed to the kernel. Alternatively, the format can also be hard-coded into custom kernels. IMA templates and fields are extensible in the kernel source code. As a result, more template fields can be added in the future.

IMA policies define which files are measured using the IMA policy language. Built-in policies can be passed as boot arguments to the kernel. Custom IMA policies can be defined once during runtime or be hard-coded into a custom kernel. If no policy is defined, no measurements are taken and IMA is effectively disabled.

A comprehensive description of the content fields in in native Linux IMA TLV format can be found in Table 16 of the Canonical Event Log (CEL) specification [cel]. The CEL specification also illustrates the use of templates to enable extended or customized IMA TLV formats in Section 5.1.6.

Appendix B. IMA for Network Equipment Boot Logs

Network equipment can generally implement similar IMA-protected functions to generate measurements (Claims) about the boot process of a device and enable corresponding remote attestation. Network Equipment Boot Logs combine the measurement and logging of boot components and operating system components (executables and files) into a single log file in a format identical to the IMA format. Note that the format used for logging measurement of boot components in this scheme differs from the boot logging strategy described
elsewhere in this document.

During the boot process of the network device, i.e., from BIOS to the end of the operating system and user-space, all files executed can be measured and logged in the order of their execution. When the Verifier initiates a remote attestation process (e.g., challenge-response remote attestation as defined in this document), the network equipment takes on the role of an Attester and can convey to the Verifier Claims that comprise the measurement log as well as the corresponding PCR values (Evidence) of a TPM.

The verifier can appraise the integrity (compliance with the Reference Values) of each executed file by comparing its measured value with the Reference Value. Based on the execution order, the Verifier can compute a PCR reference value (by replaying the log) and compare it to the Measurement Log Claims obtained in conjunction with the PCR Evidence to assess their trustworthiness with respect to an intended operational state.

Network equipment usually executes multiple components in parallel. This holds not only during the operating system loading phase, but also even during the BIOS boot phase. With this measurement log mechanism, network equipment can take on the role of an Attester, proving to the Verifier the trustworthiness of its boot process. Using the measurement log, Verifiers can precisely identify mismatching log entries to infer potentially tampered components.

This mechanism also supports scenarios that modify files on the Attester that are subsequently executed during the boot phase (e.g., updating/patching) by simply updating the appropriate Reference Values in Reference Integrity Manifests that inform Verifiers about how an Attester is composed.
