### Main points:

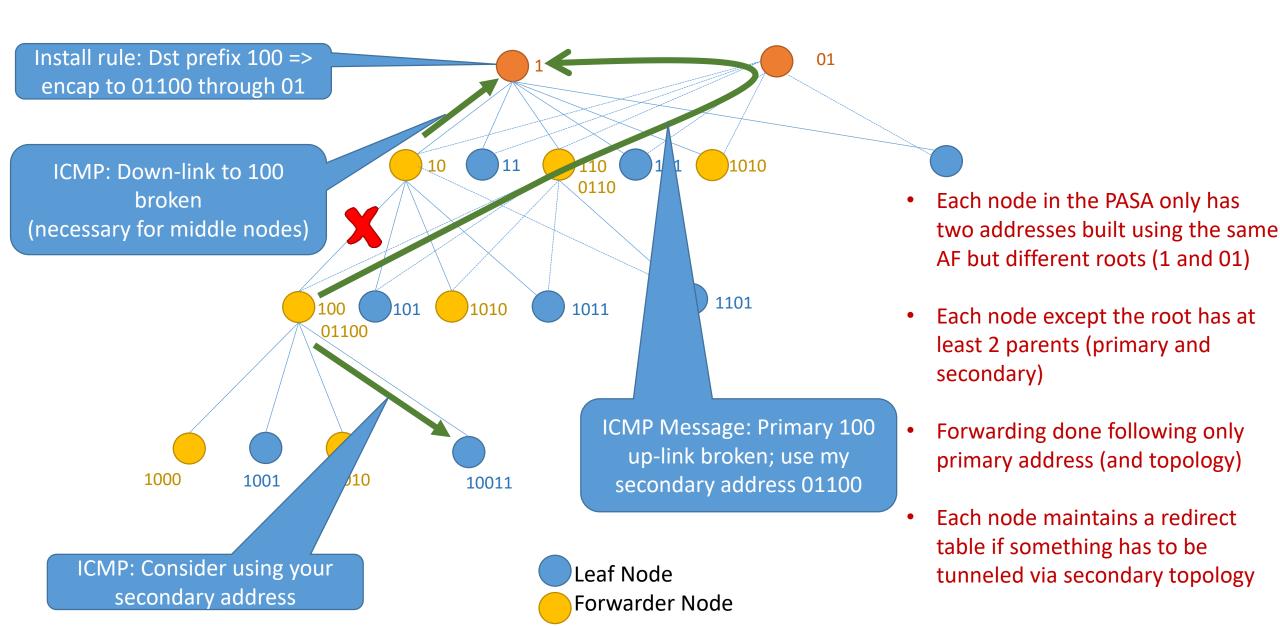

- A general introduction to the problem
- Possible solutions classes
  - See rest of the presentation
- Some considerations about failure detection and recovery
- Some considerations about robustness

## **Solutions**

- Pre-requisite
  - Presence of redundant links
  - Some not actively used
  - Active links forming a tree
  - All nodes have a secondary parent
    - Except root node
    - Alternative parent is connected through a non actively used link

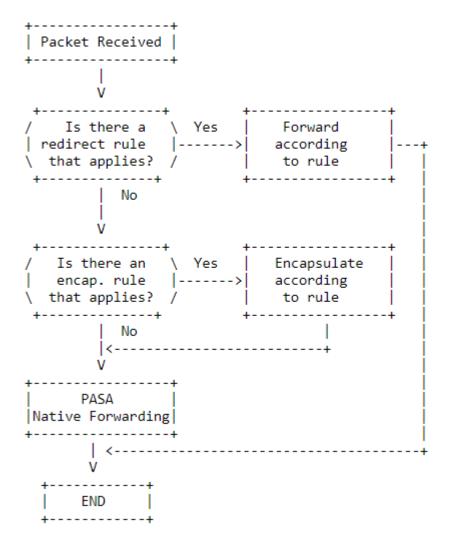

- Multi-Address:
  - using multiple addresses per node, one for each alternative parent (logically creating multiple topologies)
- Single-Address:
  - using one single address per node, store the addresses of alternative parents/children

## **Multi-address: Link Failure**

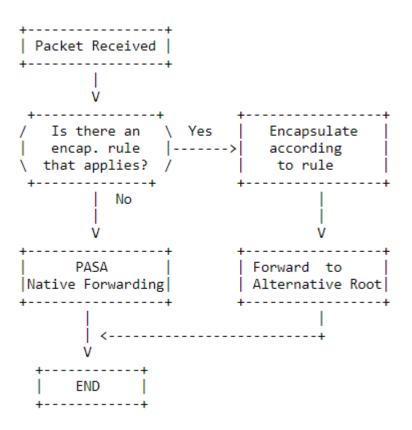

# **Multi-Address: Forwarding Operation**

#### Forwarder Nodes

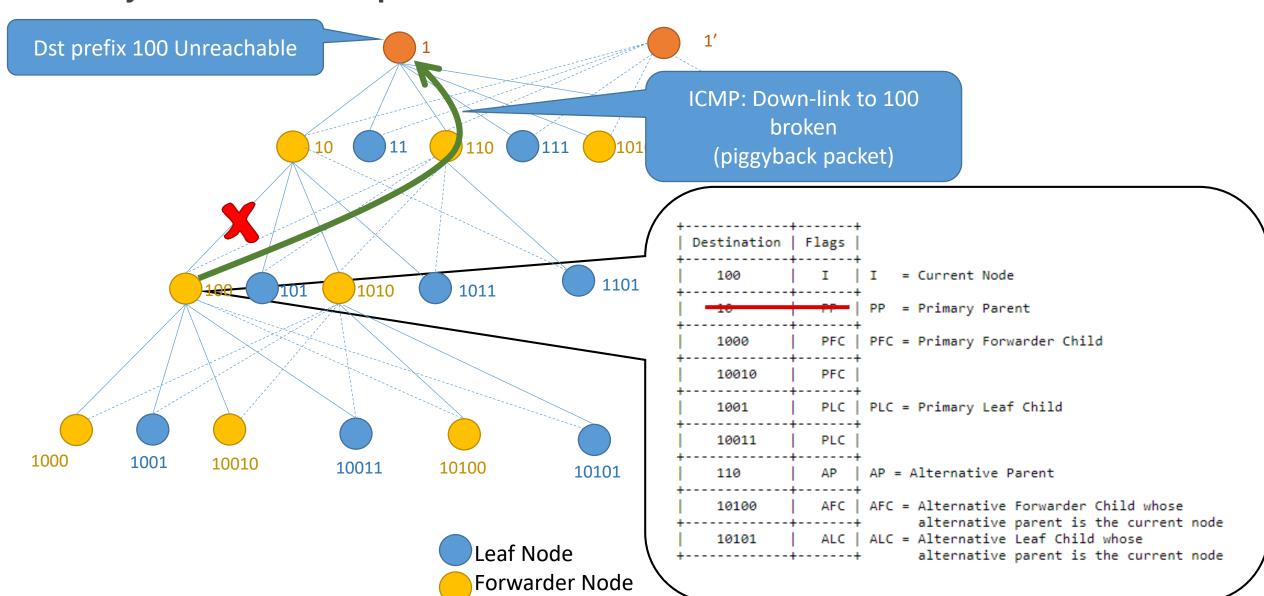

#### **Root Nodes**

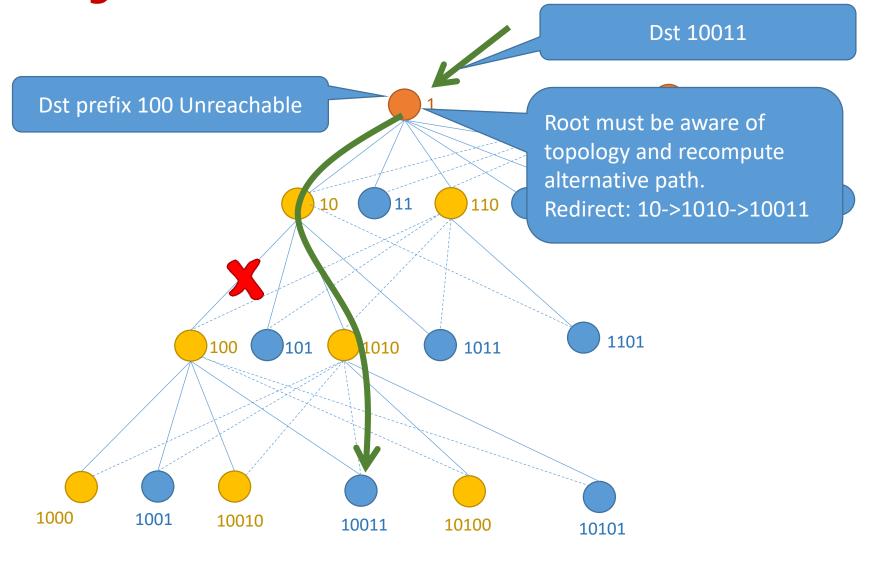

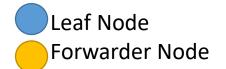

## **Single Address: Link Failure**

Locally store alternative parents/children

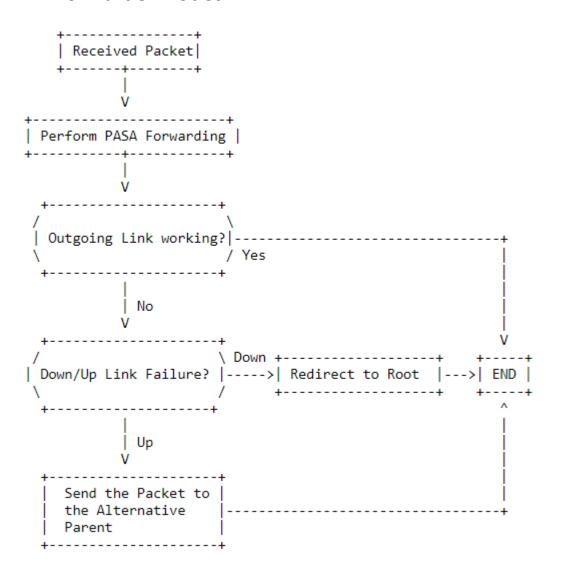

## **Single Address: Link Failure**

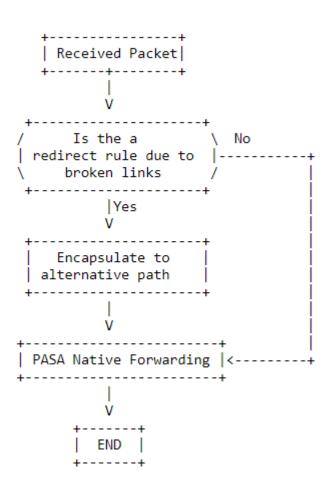

# Single-Address: Forwarding Operation

#### **Forwarder Nodes**

#### **Root Nodes**

# Multiple Addresses vs Single Address

Approach	Root State	Forwarder State	Robustness
Multiple Addresses	Low (redirect rule)	Low (redirect rule)	Lower for multiple failures (limited knowledge)
Single Address	High (topology)	Low (neighborhood)	Higher for multiple failures (root to find feasible path)

## Any question/comment welcome!
