Agenda

- Recap
 - Problem statement
 - Solution summary
- Updates to the draft
 - Deployment use cases
- Next steps

Problem Statement

- Different types of traffic may need to be routed satisfying specific constraints
- Link metric has evolved beyond traditional IGP cost
 - Delay, bandwidth as defined in IGP metric-type registry
 - Administratively assigned metric-types proposed by (draft-ietf-lsr-flex-algo-bw-con)

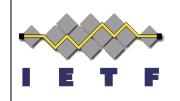

Problem Statement

- Operator may want to provision end-to-end paths across multiple AS domains
 - intent-based inter-domain routing
- AIGP attribute defined in RFC7311 can carry IGP default cost
 - 1 TLV defined AIGP TLV carries the IGP cost

Alignment between IGP metric types and AIGP metric would simplify network operations

Summary of Proposal: Generic-metric TLV

- Extensions to AIGP attribute to carry Generic-metric TLV
- New metric-type field maps to IGP metrictype registry

Figure 2: Generic-Metric TLV

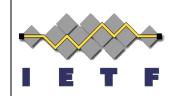

Generic-Metric TLV Type (1 octet): Code point to be assigned by IANA

Generic-Metric TLV Length (2 octets): 12

Generic-Metric TLV Value (9 octets): 2 sub-fields as shown below:

- metric-type (1 octet): Value from IGP metric-type registry.

Summary of Proposal: Usage of Generic-Metric TLV

- Originator same as RFC7311
 - encode the metric in Generic-Metric TLV
- Receiver mostly similar to RFC7311
 - metric-type of domain matches metric-type in route
 - use the received value
 - metric-type of domain differs from metric-type in route
 - normalize the local cost to route's metric-type
 - non-zero value to be added

Summary of Proposal: Best path computation

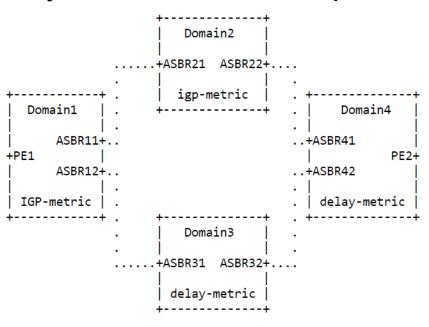

- Updates to RFC7311 Decision Process
 - generic_metric TLV preferred over AIGP TLV
 - Route R has generic-metric value = T
 - metric-type matches local domain metric-type
 - Compute C = T + n (metric to reach NH)
 - metric-type does not match local domain metric-type
 - Compute C = T + m (normalize metric to reach NH)
 - Consider routes tied with lowest value of C
 - among routes with generic_metric TLV, prefer routes with lowest metric-type

Delay-based end-to-end path from PE1-PE2

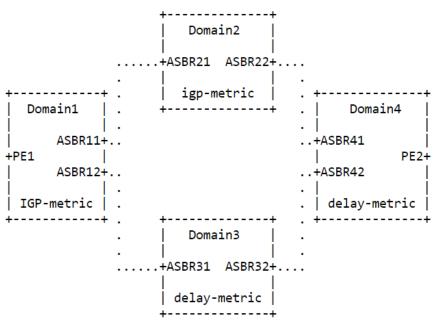

- domain1, domain2 use igp-metric
- domain3, domain4 use delay-metric

- ASBR41, ASBR42 originate route with generic-Metric TLV, metric-type is delay-metric (1).
- domain1 and domain2 normalize IGP cost before updating generic-metric
 TLV

Deployment use case2

End-to-end path based on IGP-cost but use delay-metric within a local domain

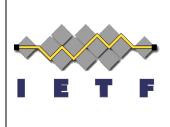

- domain1, domain2 use igp-metric
- domain3, domain4 use delay-metric

- All routers update generic-metric TLV with IGP-cost
- Intra-domain path to reach ASBR will be based on local metric-type.
- For e.g., ASBR31 choses path with lowest delay to reach ASBR32
