# Discovery of Network-designated Resolvers

IETF 118 Hackathon, Prague

# Setup

Windows 11

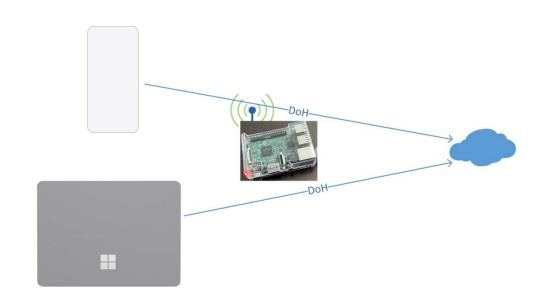

Tommy Pauly not shown

## Deployment 1: direct to cloud

Both clients used DHCPv4, requesting option 162.

Dnsmasq responded with:

| Name             | Value (in wire encoding)                    |  |
|------------------|---|--|
| Service Priority | 1   |  |
| ADN              | doh.bt.com                                  |  |
| IP Address       | 81.130.111.251                              |  |
| SvcParams        | <pre>alpn=h2 dohpath=/dns-query{?dns}</pre> |  |

### Including the router

If we deploy in a way that the router is included in DNS resolution, then private names that it knows can be resolved, and public names can be cached.

DNSdist 1.8.2 was compiled for the Pi, with relevant features.

#### It was then configured to:

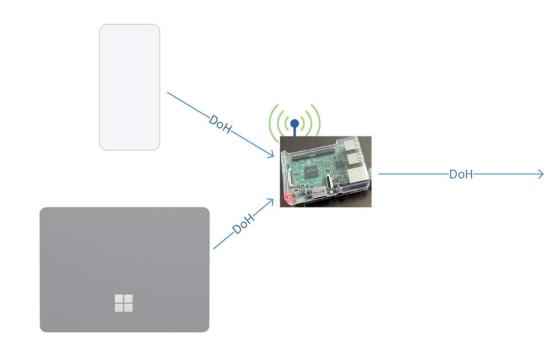

- Provide a DoH listener on https://192.168.1.254/dns-query
- Set up connections to two backend DoH resolvers, in this case two IP addresses of doh.bt.com
- Healthcheck the success of those connections in "lazy" mode appropriate to a CPE deployment. Suitable sample size, threshold, failed interval set.
- Implement a packet cache, with defined size and TTL limits.

## Deployment 2: DoH via the Pi

Both clients used DHCPv4, requesting option 162.

Dnsmasq responded with:

| Name             | Value (in wire encoding)                    |  |
|------------------|---|--|
| Service Priority | 1   |  |
| ADN              | dnrpoc. <personal domain=""></personal>     |  |
| IP Address       | 192.168.1.254                               |  |
| SvcParams        | <pre>alpn=h2 dohpath=/dns-query{?dns}</pre> |  |

# Summary of results

| Name       | Cloud        | Pi       |
|------------|--------------|----------|
| iOS        | ✓            | ✓        |
| Windows 11 | $\checkmark$ | <b>√</b> |

means encryption was used for the network segments between the user device and the recursive resolver.
