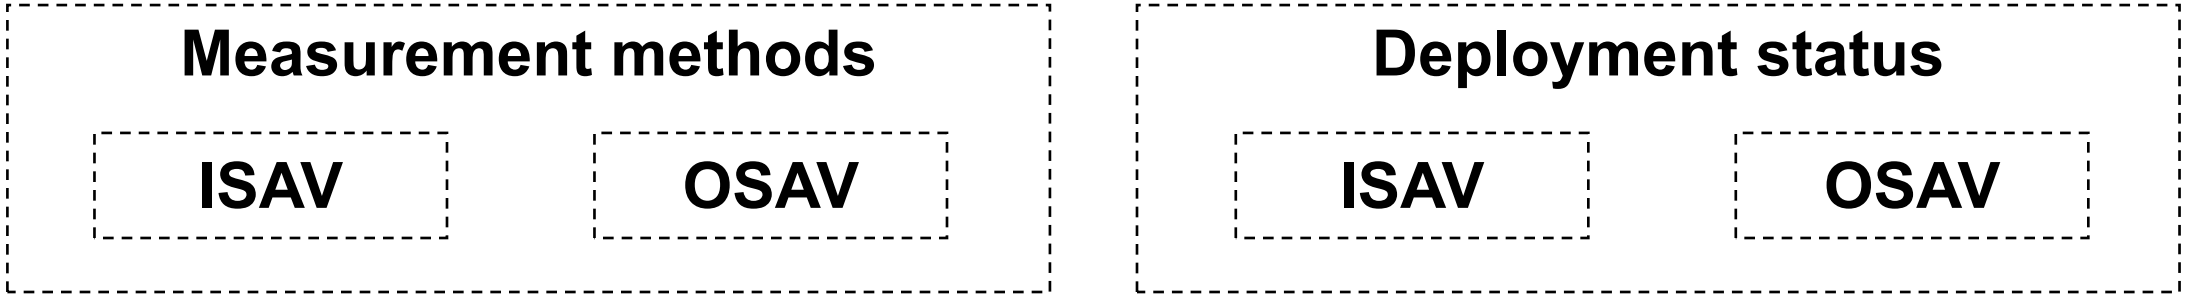
IETF 122: draft-wang-sav-deployment-status-00

Introduction

- IP spoofing, sending packets with source addresses that do not belong to the sending host, is one of the long-standing security threats in the Internet
- Source address validation (SAV) is important for protecting networks from IP spoofing attacks
  - Several techniques have been proposed to validate the source address of traffic, e.g., Access Control List (ACL), unicast Reverse Path Forwarding (uRPF), and Virtual routing and forwarding (VRF) table
- SAV can be categorized into two types: outbound SAV (OSAV) and inbound SAV (ISAV).
  - OSAV discards spoofed packets originating from within a network and destined for external destinations
  - ISAV focuses on filtering spoofed packets arriving from external sources to the network

Introduction

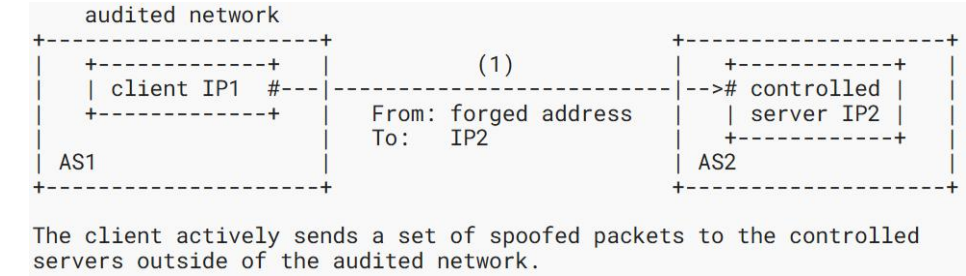
- The MANRS initiative **considers IP spoofing as one of the most common routing threats**, and defines a recommended action to mitigate spoofing traffic, encouraging network operators to implement SAV for their own infrastructure and end users, and for any Single-Homed Stub Customer Networks.
  - Only 1.6% of routed ASes participate in MANRS, and not all MANRS members follow this action to implement SAV for their networks, and .
- There is a lack of comprehensive knowledge regarding the current status of SAV deployment across the Internet community.
  - This document aims to provide a comprehensive view about SAV deployment in the Internet



OSAV Measurement Methods

Client-based Method | Proxy-based Method | DNAT-based Method

- By ***deploying a client on a host*** in the audited network, the client can ***actively generate and send spoofed packets*** to the outside of the audited network
  - **Filtering depth:** A client can incrementally set TTL of spoofed packets, and thus ***its forwarding path can be learned in a way like traceroute***
  - **Filtering granularity:** A client can generate spoofed packets with ***arbitrary IP addresses*** as its source addresses.
  - If a client is installed within a NAT network, spoofed packets may be blocked by the NAT devices
    - Only about half of ASes tesed by the CAIDA Spoofer project in 2024 were tested based on public IP addresses.



Spoofer — Helping to protect your network and the global Internet — caida

SAV-T Runner

Similarly, by using a controlled server to send spoofed packets to the client, client-based method can measure deployment of **ISAV**.

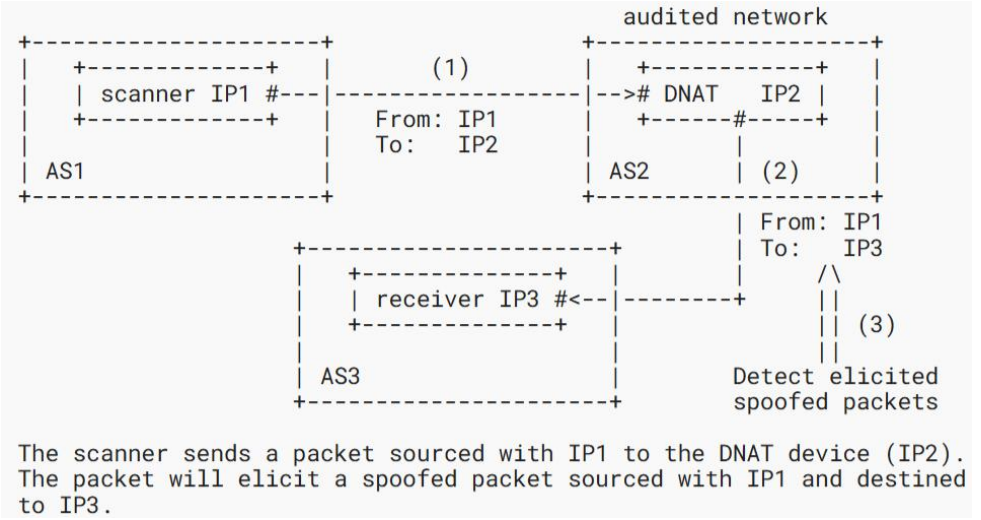
[1] https://www.caida.org/projects/spoofer/
[2] https://ki3.org.cn/#/sav-t

OSAV Measurement Methods

Client-based Method | Proxy-based Method | **DNAT-based Method**

- When matching DNAT rules, the DNAT device changes the packet's destination to a preset address but leaves the source address unchanged ➡ **Spoofed packets**

  - DNAT-based method can utilize various protocols, such as DNS、NTP and TCP, to trigger the audited network into sending spoofed packets.
  - **Filtering depth:** As DNAT devices do not reset the TTL field, the fowarding path taken by spoofed packets can be learned by ***gradually incrementing the initial TTL values*** in original packets
  - **Filtering granularity:** The scanner sends multiple original packets with ***arbitrary source IP addresses***



Similarly, the **proxy-based method** leverages misbehaving DNS proxies, but fails to measure filtering depth and filtering granularity.

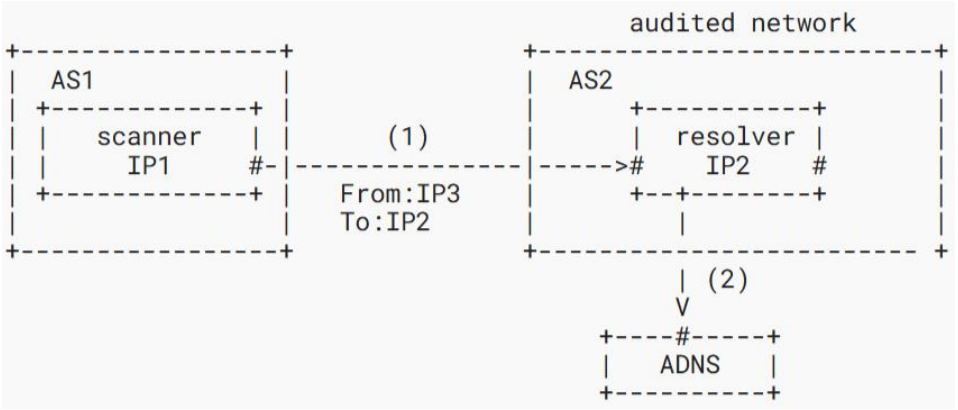
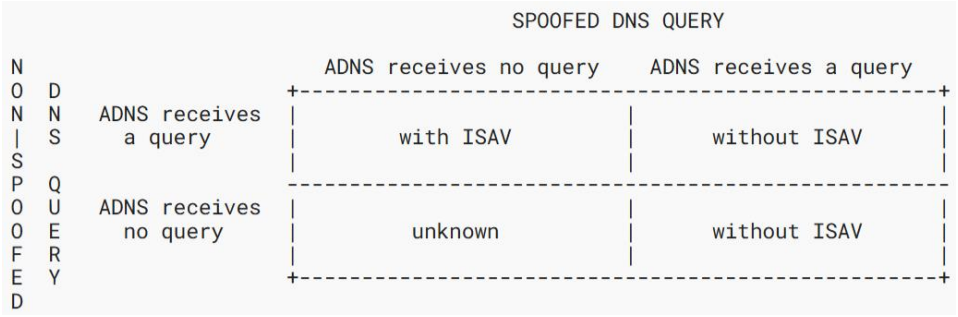
ISAV Measurement Methods

Resolver-based Method | ICMPv6-based Method | IPID-based Method | PMTUD-based Method

- The scanner first sends a DNS query with ***a forged IP address that belongs to the audited network*** (AS2), to a DNS resolver in AS2
  - If the DNS resolver receives the spoofed DNS query, it will send another DNS query to our controlled ADNS
- Then, the scanner send ***a non-spoofed DNS query*** to the same target IP address
  - By ***comparing the results of the spoofed query and the non-spoofed query***, we can infer the deployment of ISAV





[1] Nosyk Y, Korczyński M, Lone Q, et al. The closed resolver project: Measuring the deployment of inbound source address validation. IEEE/ACM ToN, 2023

ISAV Measurement Methods

Resolver-based Method | **ICMPv6-based Method** | **IPID-based Method** | **PMTUD-based Method**

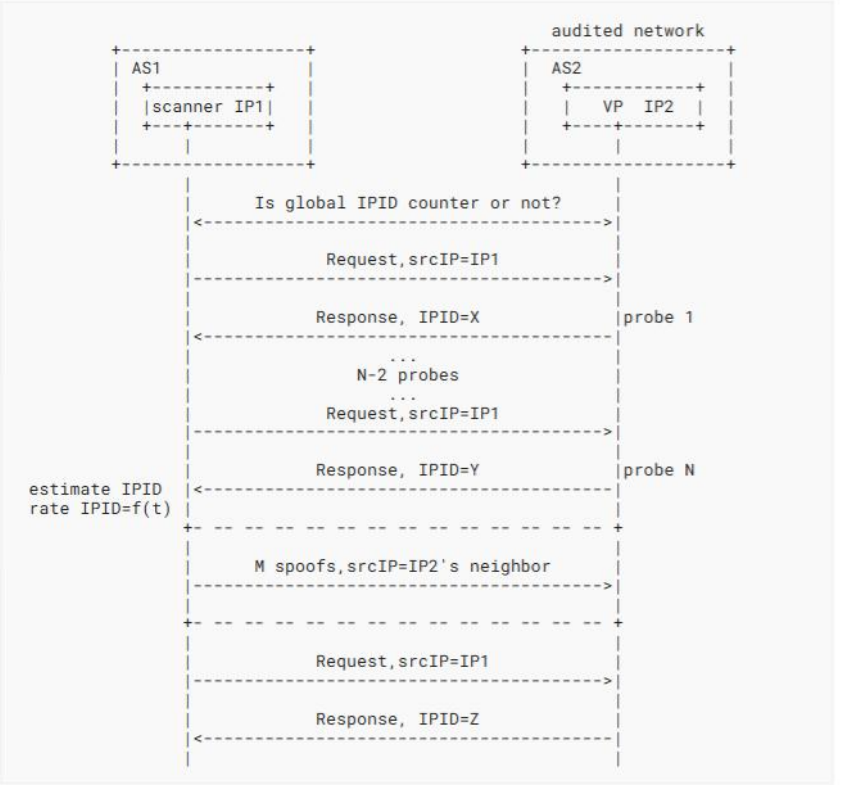
- The scanner sends ICMPv6 packets with forged source address to the target network, and use the ***rate limiting mechanism of ICMPv6*** as an observer to check whether the spoofed packets are received
  - In order to limit the bandwidth and forwarding costs incurred by originating ICMPv6 error messages, an IPv6 node MUST limit the rate of ICMPv6 error messages it originates
  - 3 rounds are conducted, and ***by comparing the number of responses received in different rounds***, we can infer the deployment of ISAV

[1] Long Pan, Jiahai Yang, Lin He, and et. al. Your Router is My Prober: Measuring IPv6 Networks via ICMP Rate Limiting Side Channels. NDSS 2023

ISAV Measurement Methods

Resolver-based Method | ICMPv6-based Method | **IPID-based Method** | PMTUD-based Method

- The scanner sends packets with forged source address to the target network, and use the ***incremental IPID value*** as an observer to check whether the spoofed packets are received
  - If a server receives a packet, it will increment its global IPID counter by 1, thus leaking information about traffic reaching the server
  - We first estimate the IPID rate of the server, then send *M* spoofed packets to it. **If the spoofed packets reach the server, the IPID will increment by *M***



Similarly, the **PMTUD-based method** send ICMP *Packet Too Big* message with forged source addresses to the server. If the spoofed packets reach the server, the server will reduce the MTU.

Deployment Status - Global Picture

- In February 2025, we used these methods to measure SAV deployment in the Internet
  - ✓ **67.4% of IPv4 and 72.8% of IPv6 ASes lack any ISAV deployment**
  - ✓ **Partial ISAV deployment is observed in 30.2% of IPv4 and 23.1% of IPv6 ASes, suggesting that these ASes deploy ISAV at their access network**
  - ✓ **14.8% of IPv4 ASes and 17.8% of IPv4 /24 prefixes demonstrate complete OSAV deployment**

Category	IPv4 ASes	IPv6 ASes
Deployed	1,157 (2.5%)	372 (4.0%)
Not Deployed	31,817 (67.4%)	6,747 (72.8%)
Partially Deployed	14,235 (30.2%)	2,143 (23.1%)

ISAV deployment status across ASes

Category	IPv4 /24 Prefixes	IPv6 /48 Prefixes
Deployed	222,362 (13.1%)	47,704 (8.1%)
Not Deployed	1,390,206 (82.0%)	404,629 (68.5%)
Partially Deployed	83,460 (4.9%)	138,693 (23.5%)

ISAV deployment status across prefixes

Category	IPv4 ASes	IPv6 ASes
Deployed	409 (14.8%)	318 (71.6%)
Undeployed	2,200 (79.6%)	81 (18.2%)
Partially Deployed	155 (5.6%)	45 (10.1%)

OSAV deployment status across ASes

Category	IPv4 /24 Prefixes	IPv6 /48 Prefixes
Deployed	1,402 (17.8%)	679 (80.9%)
Undeployed	6,335 (80.4%)	130 (15.5%)
Partially Deployed	140 (1.8%)	30 (3.6%)

OSAV deployment status across prefixes

Deployment Status - Global Picture

- 91.52% of OSAV are deployed within 2 hops from the endpoints - with complete absence beyond 10 hops
- The prefix length of /20-/24 dominates OSAV deployment (55%)
  - ✓ These prefix lengths correspond to standard IPv4 allocation units for ASes. Hence, this suggests OSAV is predominantly deployed at AS border interfaces.
- 41.66% of networks filter inbound spoofing packets at /29-/30 granularity
  - ✓ This suggests ISAV is predominantly deployed in access networks

ISAV filtering granularity (IPv4)

Deployment Status - Deployment in Countries/Regions

- China, South Korea, Germany, and France demonstrate higher OSAV deployment ratios, while Russia, Brazil, and India show lower OSAV deployment ratios
- ISAV deployment remains limited in most regions, with South Korea, Chinese Taiwan and Poland exhibiting more advanced ISAV deployment

ISAV deployment

Deployment Status - Comparison between ISAV and OSAV

- G-Network (AS272122), DigitalOcean (AS14061), Korea Telecom (AS4766) and China Telecom (AS4134) achieve over 90% OSAV deployment
- Chungwa Telecom (AS3462), Korea Telecom (AS4766), Charter (AS20115), and Comcast (AS7922) demonstrate significantly higher ISAV deployment

ASN	OSAV Tested Prefixes	OSAV Deployment Ratio

749	70,399	1.2%
36947	11,339	0.4%

ISAV deployment

Deployment Status - Comparison between ISAV and OSAV

- We find a positive correlation between the deployment of OSAV and ISAV
  - **10.9%** of ASes that deploy ISAV also deploy OSAV, while only **5.9%** of ASes without ISAV deploy OSAV
  - **36.0%** of ASes that deploy OSAV also deploy ISAV, while only **22.6%** of ASes without OSAV deploy ISAV

Deployment Status - Impact of MANRS

- To understand the impact of MANRS on SAV deployment, we compare SAV deployment ratios between MANRS and non-MANRS networks, including both full and partial deployments
- MANRS networks demonstrate superior SAV deployment
  - For OSAV, **29.1%** in MANRS networks versus **19.6%** in non-MANRS networks
  - For ISAV, **73.3%** in MANRS networks versus **56.7%** in non-MANRS networks
- These results indicate that ***although anti-spoofing is a recommended action, MANRS participation improves SAV deployment across network configurations***.

	OSAV Deployment Ratio	ISAV Deployment Ratio
MANRS	29.1%	73.3%
Non-MANRS	19.6%	56.7%
