NETFLIX

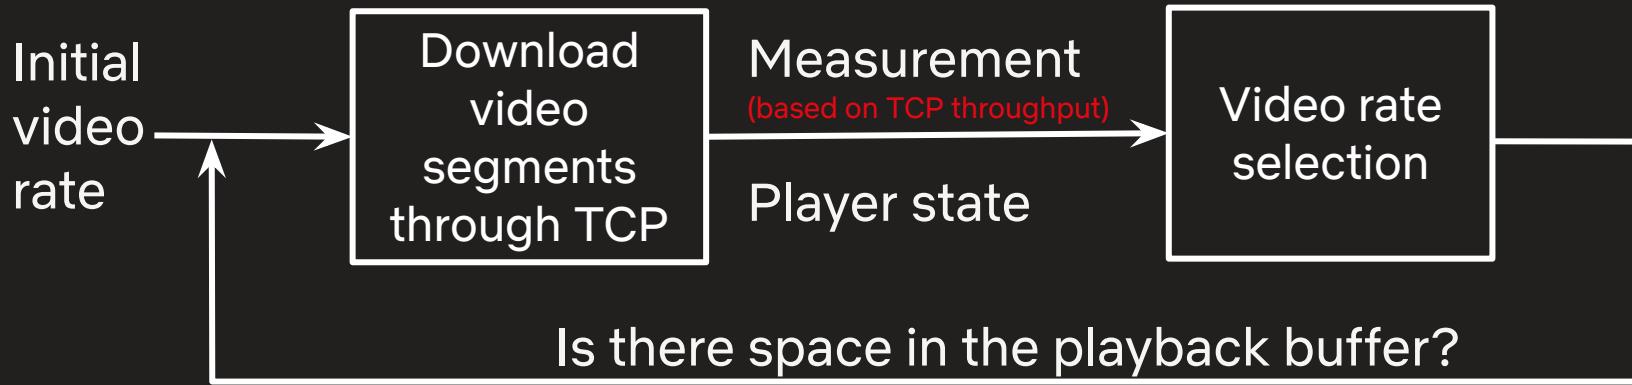

The takeaways of this talk

- Netflix is combining Adaptive Bitrate (ABR) and Congestion Control (CC)
 - ABR & CC **needs** to work together
 - Less bursty traffic, better QoE
- YouTube is experimenting with similar ideas
 - They also found it beneficial

Combining ABR & CC is good for everyone.

You should try it out.

How does ABR + CC work together today?

The decisions from ABR & CC intertwine with each other.

Confused, Timid, and Unstable: Picking a Video Streaming Rate is Hard

ABSTRACT

Today's commercial video streaming services use dynamic rate selection to provide a high-quality user experience. Most services host content on standard HTTP servers in CDNs, so rate selection must occur at the client. We measure three popular video streaming services – Hulu, Netflix, and Vudu – and find that accurate client-side bandwidth estimation above the HTTP layer is hard. As a result, rate selection based on inaccurate estimates can trigger a feedback loop, leading to undesirably variable and low-quality video. We call this phenomenon the *downward spiral effect*, and we measure it on all three services, present insights into its root causes, and validate initial solutions to prevent it.

ABSTRACT

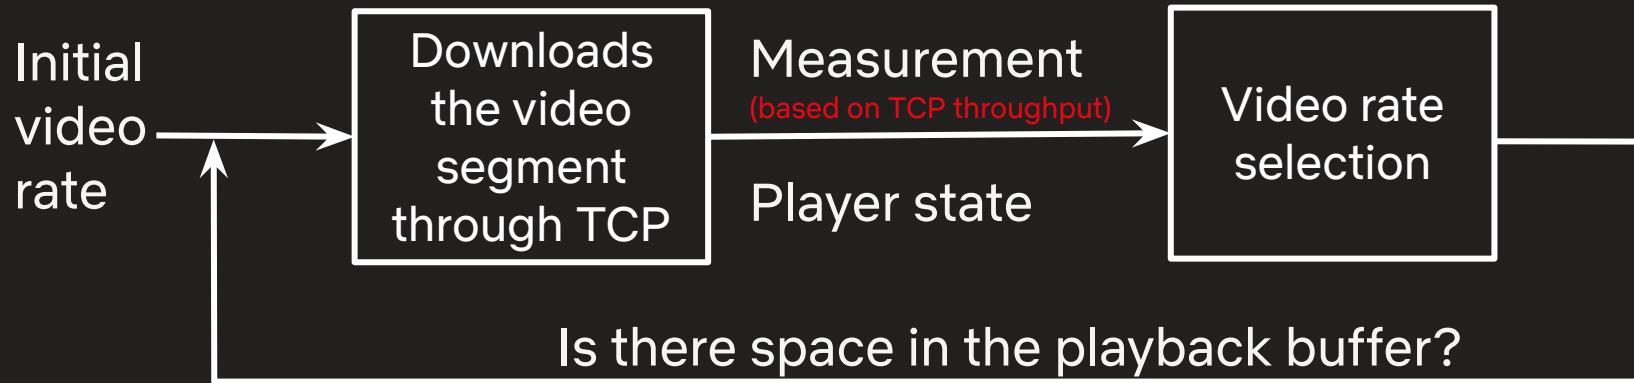

On-demand streaming video traffic is managed by an adaptive bitrate (ABR) algorithm whose job is to optimize quality of experience (QoE) for a single video session. ABR algorithms leave the question of sharing network resources up to transport-layer algorithms. We observe that as the internet gets faster relative to video streaming rates, this delegation of responsibility gives video traffic a burstier on-off traffic pattern. In this paper, we show we can substantially smooth video traffic to improve its interactions with the rest of the internet, while maintaining the same or better QoE for streaming video. We smooth video traffic with two design principles:

Combining them can achieve great things!

SIGCOMM'23

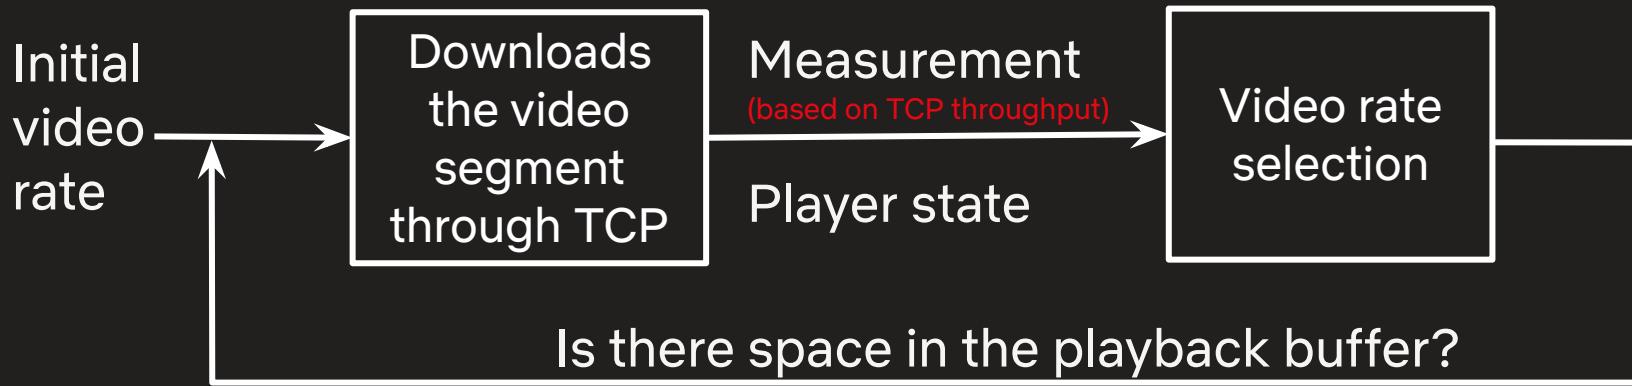

How does ABR + CC work together today?

What goes wrong in this picture?

How do we make it better?

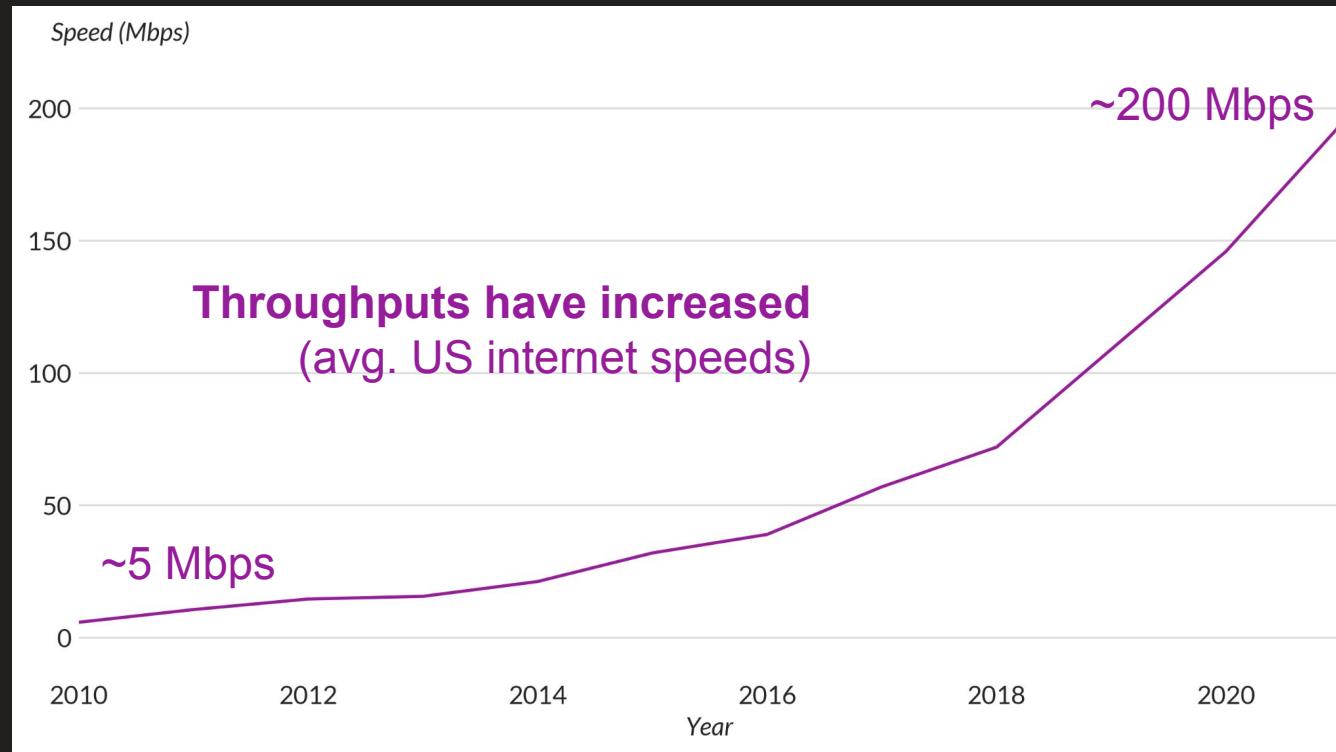

How does ABR + CC work together today?

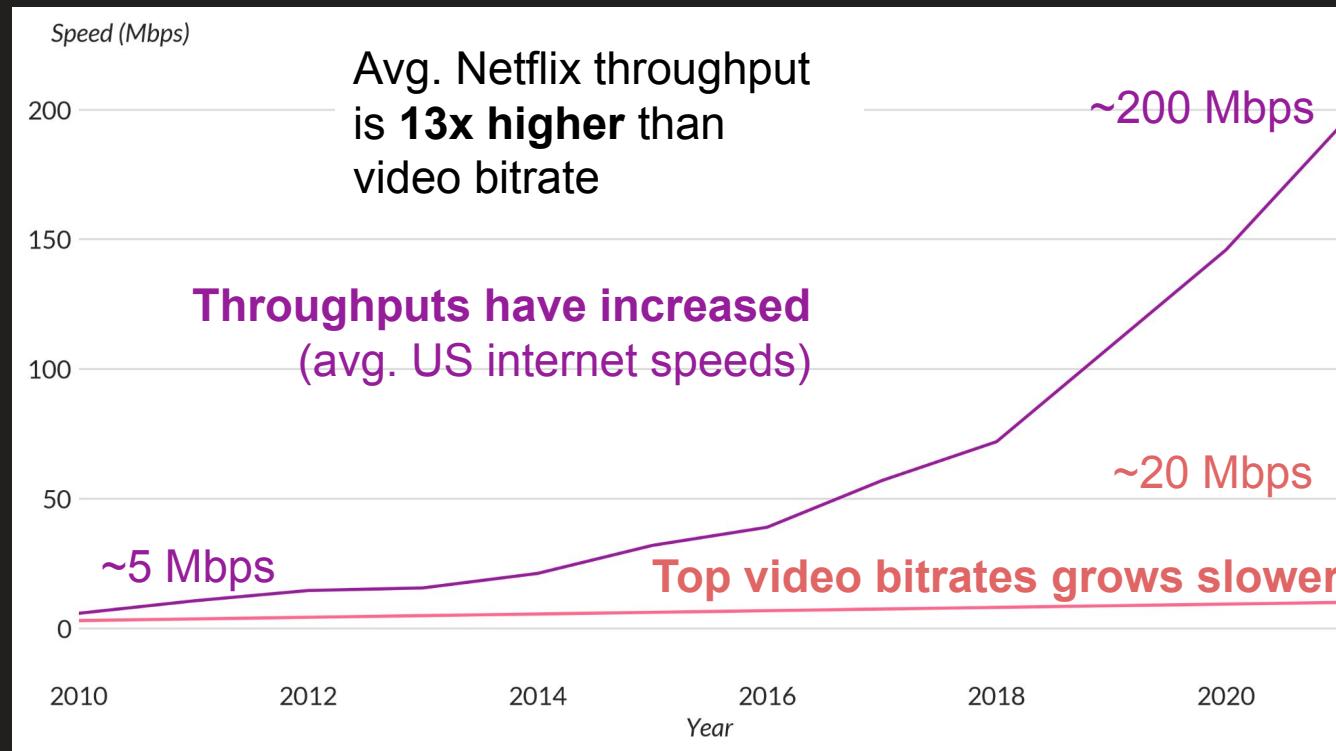

TCP aims to fully utilize its fair share.

App-informed pacing

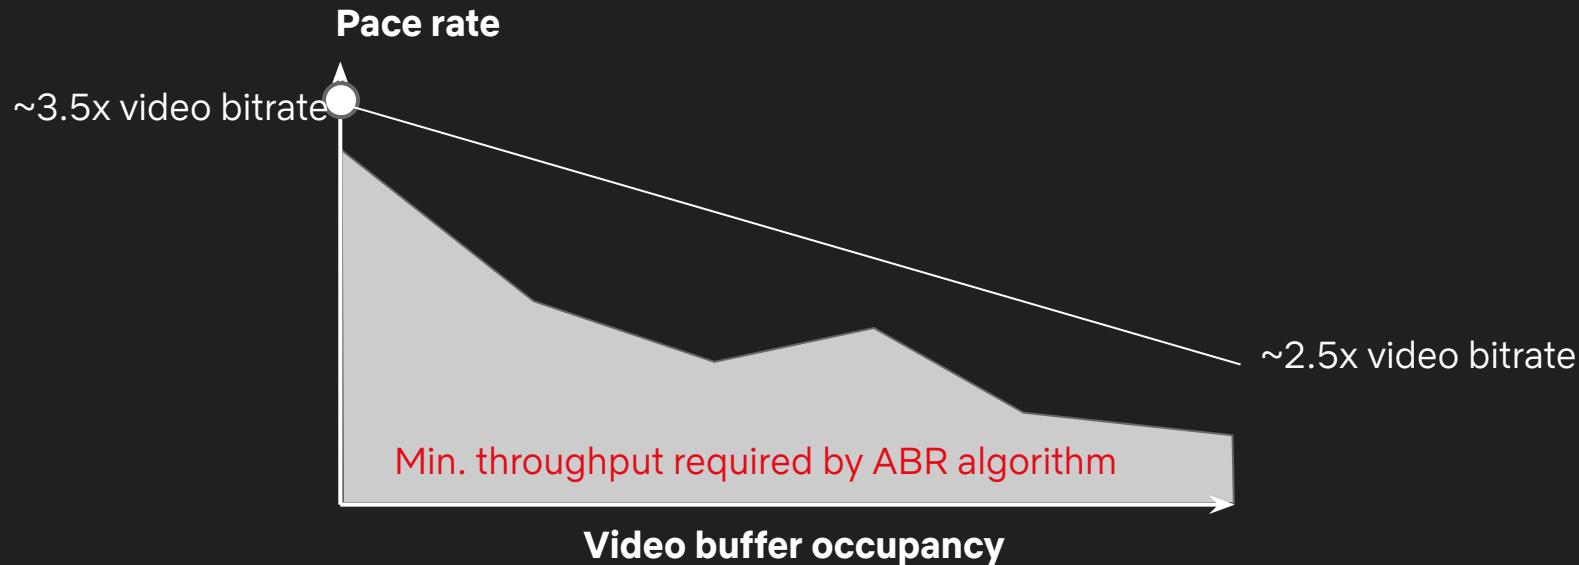

ABR should inform CC to pace based on the QoE needs

Just need enough throughput for ABR algorithm to pick highest bitrate

ABR should inform CC to pace based on the QoE needs

Just need enough throughput for ABR algorithm to pick highest bitrate

ABR should inform CC to pace based on the QoE needs

Just need enough throughput for ABR algorithm to pick highest bitrate

Large-scale experiments at Netflix

App-informed pacing reduces congestion-related metrics:

Metric	Results
Instantaneous Throughput	62% lower
Retransmissions	50% lower
Round-trip times	19% lower

All with QoE *improvements* (see paper for details)

Promising results towards combining ABR & CC

What now?

- YouTube is experimenting with similar techniques
- Netflix is in the process of rolling out app-informed pacing
 - Productization considerations:
 - Server CPU consumption
 - Mobile client power consumption
 - On track to fully productization soon
- Netflix and YouTube are working together to quantify some of the benefits
