Network Configuration Protocol (NETCONF)
draft-ietf-netconf-4741bis-10

Abstract

The Network Configuration Protocol (NETCONF) defined in this document provides mechanisms to install, manipulate, and delete the configuration of network devices. It uses an Extensible Markup Language (XML)-based data encoding for the configuration data as well as the protocol messages. The NETCONF protocol operations are realized as Remote Procedure Calls (RPC). This document obsoletes RFC 4741.

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on September 15, 2011.

1. Introduction

The NETCONF protocol defines a simple mechanism through which a network device can be managed, configuration data information can be retrieved, and new configuration data can be uploaded and manipulated. The protocol allows the device to expose a full, formal application programming interface (API). Applications can use this straightforward API to send and receive full and partial configuration data sets.

The NETCONF protocol uses a remote procedure call (RPC) paradigm. A client encodes an RPC in XML [W3C.REC-xml-20001006] and sends it to a server using a secure, connection-oriented session. The server responds with a reply encoded in XML. The contents of both the request and the response are fully described in XML DTDs or XML schemas, or both, allowing both parties to recognize the syntax constraints imposed on the exchange.

A key aspect of NETCONF is that it allows the functionality of the management protocol to closely mirror the native functionality of the device. This reduces implementation costs and allows timely access to new features. In addition, applications can access both the syntactic and semantic content of the device's native user interface.

NETCONF allows a client to discover the set of protocol extensions supported by a server. These "capabilities" permit the client to adjust its behavior to take advantage of the features exposed by the device. The capability definitions can be easily extended in a noncentralized manner. Standard and non-standard capabilities can be defined with semantic and syntactic rigor. Capabilities are discussed in Section 8.

The NETCONF protocol is a building block in a system of automated configuration. XML is the lingua franca of interchange, providing a flexible but fully specified encoding mechanism for hierarchical content. NETCONF can be used in concert with XML-based transformation technologies, such as XSLT [W3C.REC-xslt-19991116], to provide a system for automated generation of full and partial configurations. The system can query one or more databases for data about networking topologies, links, policies, customers, and services. This data can be transformed using one or more XSLT scripts from a task-oriented, vendor-independent data schema into a form that is specific to the vendor, product, operating system, and software release. The resulting data can be passed to the device using the NETCONF protocol.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this

document are to be interpreted as described in RFC 2119 [RFC2119].

1.1. Terminology

- o candidate configuration datastore: A configuration datastore that can be manipulated without impacting the device's current configuration and that can be committed to the running configuration datastore. Not all devices support a candidate configuration datastore.
- o capability: A functionality that supplements the base NETCONF specification.
- o client: A client invokes protocol operations on a server. In addition, a client can subscribe to receive notifications from a server.
- o configuration data: Configuration data is the set of writable data that is required to transform a system from its initial default state into its current state.
- o datastore: A conceptual place to store and access information. A datastore might be implemented, for example, using files, a database, flash memory locations or combinations thereof.
- o configuration datastore: A configuration datastore is defined as the datastore holding the complete set of configuration data that is required to get a device from its initial default state into a desired operational state.
- o message: A protocol element sent over a session. Messages are well-formed XML documents.
- o notification: A server initiated message indicating that a certain event has been recognized by the server.
- o protocol operation: A specific remote procedure call, as used within the NETCONF protocol.
- o remote procedure call: A remote procedure call (RPC), realized by exchanging <rpc> and <rpc-reply> messages.
- o running configuration datastore: A configuration datastore holding the complete configuration currently active on the device. The running configuration datastore always exists.
- o server: A server executes protocol operations invoked by a client. In addition, a server can send notifications to a client.

- o session: Client and server exchange messages using a secure, connection-oriented session.
- o startup configuration datastore: The configuration datastore holding the configuration loaded by the device when it boots. Only present on devices that separate the startup configuration datastore from the running configuration datastore.
- o state data: State data is the additional data on a system that is not configuration data such as read-only status information and collected statistics.
- o user: The authenticated identity of the client. The authenticated identity of a client is commonly referred to as the NETCONF username.

1.2. Protocol Overview

NETCONF uses a simple RPC-based mechanism to facilitate communication between a client and a server. The client can be a script or application typically running as part of a network manager. The server is typically a network device. The terms "device" and "server" are used interchangeably in this document, as are "client" and "application".

A NETCONF session is the logical connection between a network administrator or network configuration application and a network device. A device **MUST** support at least one NETCONF session and **SHOULD** support multiple sessions. Global configuration attributes can be changed during any authorized session, and the effects are visible in all sessions. Session-specific attributes affect only the session in which they are changed.

NETCONF can be conceptually partitioned into four layers as shown in Figure 1.

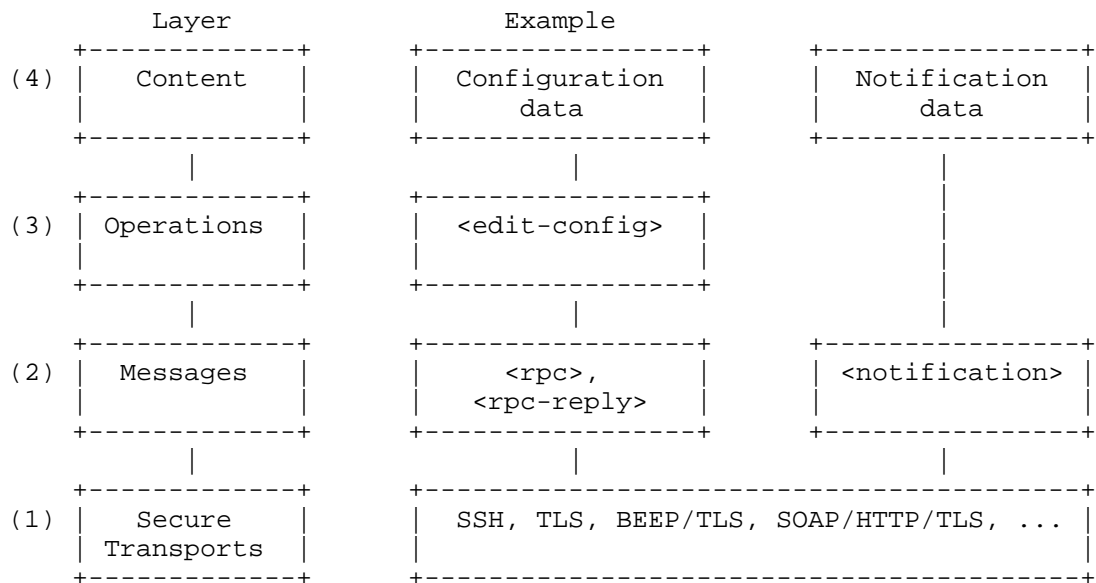

Figure 1: NETCONF Protocol Layers

1. The Secure Transport layer provides a communication path between the client and server. NETCONF can be layered over any transport protocol that provides a set of basic requirements. Section 2 discusses these requirements.
2. The Messages layer provides a simple, transport-independent framing mechanism for encoding RPCs and notifications. Section 4 documents the RPC messages, and [RFC5717] documents notifications.
3. The Operations layer defines a set of base protocol operations invoked as RPC methods with XML-encoded parameters. Section 7 details the list of base protocol operations.
4. The Content layer is outside the scope of this document. It is expected that separate efforts to standardize NETCONF data models will be undertaken.

The YANG data modeling language [RFC6020] has been developed for specifying NETCONF data models and protocol operations, covering the Operations and the Content layers of Figure 1.

1.3. Capabilities

A NETCONF capability is a set of functionality that supplements the base NETCONF specification. The capability is identified by a uniform resource identifier (URI) [RFC3986].

Capabilities augment the base operations of the device, describing both additional operations and the content allowed inside operations. The client can discover the server's capabilities and use any additional operations, parameters, and content defined by those capabilities.

The capability definition might name one or more dependent capabilities. To support a capability, the server **MUST** support any capabilities upon which it depends.

Section 8 defines the capabilities exchange that allows the client to discover the server's capabilities. Section 8 also lists the set of capabilities defined in this document.

Additional capabilities can be defined at any time in external documents, allowing the set of capabilities to expand over time. Standards bodies can define standardized capabilities, and implementations can define proprietary ones. A capability URI **MUST** sufficiently distinguish the naming authority to avoid naming collisions.

1.4. Separation of Configuration and State Data

The information that can be retrieved from a running system is separated into two classes, configuration data and state data. Configuration data is the set of writable data that is required to transform a system from its initial default state into its current state. State data is the additional data on a system that is not configuration data such as read-only status information and collected statistics. When a device is performing configuration operations, a number of problems would arise if state data were included:

- o Comparisons of configuration data sets would be dominated by irrelevant entries such as different statistics.
- o Incoming data could contain nonsensical requests, such as attempts to write read-only data.
- o The data sets would be large.
- o Archived data could contain values for read-only data items, complicating the processing required to restore archived data.

To account for these issues, the NETCONF protocol recognizes the difference between configuration data and state data and provides operations for each. The <get-config> operation retrieves configuration data only, while the <get> operation retrieves configuration and state data.

Note that the NETCONF protocol is focused on the information required to get the device into its desired running state. The inclusion of other important, persistent data is implementation specific. For example, user files and databases are not treated as configuration data by the NETCONF protocol.

For example, if a local database of user authentication data is stored on the device, it is an implementation-dependent matter whether it is included in configuration data.

2. Transport Protocol Requirements

NETCONF uses an RPC-based communication paradigm. A client sends a series of one or more RPC request messages, which cause the server to respond with a corresponding series of RPC reply messages.

The NETCONF protocol can be layered on any transport protocol that provides the required set of functionality. It is not bound to any particular transport protocol, but allows a mapping to define how it can be implemented over any specific protocol.

The transport protocol **MUST** provide a mechanism to indicate the session type (client or server) to the NETCONF protocol layer.

This section details the characteristics that NETCONF requires from the underlying transport protocol.

2.1. Connection-Oriented Operation

NETCONF is connection-oriented, requiring a persistent connection between peers. This connection **MUST** provide reliable, sequenced data delivery. NETCONF connections are long-lived, persisting between protocol operations.

In addition, resources requested from the server for a particular connection **MUST** be automatically released when the connection closes, making failure recovery simpler and more robust. For example, when a lock is acquired by a client, the lock persists until either it is explicitly released or the server determines that the connection has been terminated. If a connection is terminated while the client holds a lock, the server can perform any appropriate recovery. The <lock> operation is further discussed in Section 7.5.

2.2. Authentication, Integrity, and Confidentiality

NETCONF connections **MUST** provide authentication, data integrity, confidentiality, and replay protection. NETCONF depends on the transport protocol for this capability. A NETCONF peer assumes that appropriate levels of security and confidentiality are provided independently of this document. For example, connections could be encrypted using TLS [RFC5246] or SSH [RFC4251], depending on the underlying protocol.

NETCONF connections **MUST** be authenticated. The transport protocol is responsible for authentication of the server to the client and authentication of the client to the server. A NETCONF peer assumes that the connection's authentication information has been validated by the underlying transport protocol using sufficiently trustworthy

mechanisms and that the peer's identity has been sufficiently proven.

One goal of NETCONF is to provide a programmatic interface to the device that closely follows the functionality of the device's native interface. Therefore, it is expected that the underlying protocol uses existing authentication mechanisms available on the device. For example, a NETCONF server on a device that supports RADIUS [RFC2865] might allow the use of RADIUS to authenticate NETCONF sessions.

The authentication process MUST result in an authenticated client identity whose permissions are known to the server. The authenticated identity of a client is commonly referred to as the NETCONF username. The username is a string of characters that match the "Char" production from section 2.2 of [W3C.REC-xml-20001006] . The algorithm used to derive the username is transport protocol specific and in addition specific to the authentication mechanism used by the transport protocol. The transport protocol MUST provide a username to be used by the other NETCONF layers.

The access permissions of a given client, identified by its NETCONF username, are part of the configuration of the NETCONF server. These permissions MUST be enforced during the remainder of the NETCONF session. The details how access control is configured is outside the scope of this document.

2.3. Mandatory Transport Protocol

A NETCONF implementation MUST support the SSH transport protocol mapping [I-D.ietf-netconf-rfc4742bis].

3. XML Considerations

XML serves as the encoding format for NETCONF, allowing complex hierarchical data to be expressed in a text format that can be read, saved, and manipulated with both traditional text tools and tools specific to XML.

All NETCONF messages MUST be well-formed XML, encoded in UTF-8 [RFC3629]. If a peer receives an <rpc> message that is not well-formed XML or not encoded in UTF-8, it SHOULD reply with a "malformed-message" error. If a reply cannot be sent for any reason, the server MUST terminate the session.

A NETCONF message MAY begin with an XML declaration (see section 2.8 of [W3C.REC-xml-20001006]).

This section discusses a small number of XML-related considerations pertaining to NETCONF.

3.1. Namespace

All NETCONF protocol elements are defined in the following namespace:

urn:ietf:params:xml:ns:netconf:base:1.0

NETCONF capability names MUST be URIs [RFC3986]. NETCONF capabilities are discussed in Section 8.

3.2. Document Type Declarations

Document type declarations (see section 2.8 of [W3C.REC-xml-20001006]) MUST NOT appear in NETCONF content.

4. RPC Model

The NETCONF protocol uses an RPC-based communication model. NETCONF peers use `<rpc>` and `<rpc-reply>` elements to provide transport protocol-independent framing of NETCONF requests and responses.

The syntax and XML encoding of the Messages layer RPCs are formally defined in the XML schema in Appendix B.

4.1. `<rpc>` Element

The `<rpc>` element is used to enclose a NETCONF request sent from the client to the server.

The `<rpc>` element has a mandatory attribute "message-id", which is a string chosen by the sender of the RPC that will commonly encode a monotonically increasing integer. The receiver of the RPC does not decode or interpret this string but simply saves it to be used as a "message-id" attribute in any resulting `<rpc-reply>` message. The sender MUST ensure that the "message-id" value is normalized according to the XML attribute value normalization rules defined in [W3C.REC-xml-20001006] if the sender wants the string to be returned unmodified. For example:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <some-method>
    <!-- method parameters here... -->
  </some-method>
</rpc>
```

If additional attributes are present in an `<rpc>` element, a NETCONF peer MUST return them unmodified in the `<rpc-reply>` element. This includes any "xmlns" attributes.

The name and parameters of an RPC are encoded as the contents of the `<rpc>` element. The name of the RPC is an element directly inside the `<rpc>` element, and any parameters are encoded inside this element.

The following example invokes a method called `<my-own-method>`, which has two parameters, `<my-first-parameter>`, with a value of "14", and `<another-parameter>`, with a value of "fred":

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <my-own-method xmlns="http://example.net/me/my-own/1.0">
    <my-first-parameter>14</my-first-parameter>
    <another-parameter>fred</another-parameter>
  </my-own-method>
</rpc>
```

The following example invokes a `<rock-the-house>` method with a `<zip-code>` parameter of "27606-0100":

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <rock-the-house xmlns="http://example.net/rock/1.0">
    <zip-code>27606-0100</zip-code>
  </rock-the-house>
</rpc>
```

The following example invokes the NETCONF `<get>` method with no parameters:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get/>
</rpc>
```

4.2. `<rpc-reply>` Element

The `<rpc-reply>` message is sent in response to an `<rpc>` message.

The `<rpc-reply>` element has a mandatory attribute "message-id", which is equal to the "message-id" attribute of the `<rpc>` for which this is a response.

A NETCONF server MUST also return any additional attributes included in the `<rpc>` element unmodified in the `<rpc-reply>` element.

The response data is encoded as one or more child elements to the `<rpc-reply>` element.

For example:

The following `<rpc>` element invokes the NETCONF `<get>` method and includes an additional attribute called "user-id". Note that the "user-id" attribute is not in the NETCONF namespace. The returned `<rpc-reply>` element returns the "user-id" attribute, as well as the requested content.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
  xmlns:ex="http://example.net/content/1.0"
  ex:user-id="fred">
  <get/>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
  xmlns:ex="http://example.net/content/1.0"
  ex:user-id="fred">
  <data>
    <!-- contents here... -->
  </data>
</rpc-reply>
```

4.3. <rpc-error> Element

The <rpc-error> element is sent in <rpc-reply> messages if an error occurs during the processing of an <rpc> request.

If a server encounters multiple errors during the processing of an <rpc> request, the <rpc-reply> MAY contain multiple <rpc-error> elements. However, a server is not required to detect or report more than one <rpc-error> element, if a request contains multiple errors. A server is not required to check for particular error conditions in a specific sequence. A server MUST return an <rpc-error> element if any error conditions occur during processing.

A server MUST NOT return application-level- or data-model-specific error information in an <rpc-error> element for which the client does not have sufficient access rights.

The <rpc-error> element includes the following information:

error-type: Defines the conceptual layer that the error occurred.

Enumeration. One of:

- * transport (layer: Secure Transport)
- * rpc (layer: Messages)
- * protocol (layer: Operations)
- * application (layer: Content)

error-tag: Contains a string identifying the error condition. See Appendix A for allowed values.

error-severity: Contains a string identifying the error severity, as determined by the device. One of:

- * error
- * warning

Note that there are no <error-tag> values defined in this document which utilize the "warning" enumeration. This is reserved for future use.

error-app-tag: Contains a string identifying the data-model-specific or implementation-specific error condition, if one exists. This element will not be present if no appropriate application error tag can be associated with a particular error condition. If a data-model specific and a implementation-specific error-app-tag both exist, then the data-model specific value MUST be used by the server.

error-path: Contains the absolute XPath [W3C.REC-xpath-19991116] expression identifying the element path to the node that is associated with the error being reported in a particular <rpc-error> element. This element will not be present if no appropriate payload element or datastore node can be associated with a particular error condition.

The XPath expression is interpreted in the following context:

- * The set of namespace declarations are those in scope on the <rpc-error> element.
- * The set of variable bindings is empty.
- * The function library is the core function library.

The context node depends on the node associated with the error being reported:

- * If a payload element can be associated with the error, the context node is the rpc request's document node (i.e., the <rpc> element).
- * Otherwise, the context node is the root of all data models, i.e., the node which has the top-level nodes from all data models as children.

error-message: Contains a string suitable for human display that describes the error condition. This element will not be present if no appropriate message is provided for a particular error condition. This element SHOULD include an "xml:lang" attribute as defined in [W3C.REC-xml-20001006] and discussed in [RFC3470].

error-info: Contains protocol- or data-model-specific error content. This element will not be present if no such error content is provided for a particular error condition. The list in Appendix A defines any mandatory error-info content for each error. After any protocol-mandated content, a data model definition MAY mandate that certain application-layer error information be included in the error-info container. An implementation MAY include additional elements to provide extended and/or implementation-specific debugging information.

Appendix A enumerates the standard NETCONF errors.

Example:

An error is returned if an <rpc> element is received without a "message-id" attribute. Note that only in this case is it acceptable for the NETCONF peer to omit the "message-id" attribute in the <rpc-reply> element.

```
<rpc xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
  </get-config>
</rpc>

<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <rpc-error>
    <error-type>rpc</error-type>
    <error-tag>missing-attribute</error-tag>
    <error-severity>error</error-severity>
    <error-info>
      <bad-attribute>message-id</bad-attribute>
      <bad-element>rpc</bad-element>
    </error-info>
  </rpc-error>
</rpc-reply>
```

The following <rpc-reply> illustrates the case of returning multiple

<rpc-error> elements.

Note that the data models used in the examples in this section use the <name> element to distinguish between multiple instances of the <interface> element.

```
<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
  xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
  <rpc-error>
    <error-type>application</error-type>
    <error-tag>invalid-value</error-tag>
    <error-severity>error</error-severity>
    <error-path xmlns:t="http://example.com/schema/1.2/config">
      /t:top/t:interface[t:name="Ethernet0/0"]/t:mtu
    </error-path>
    <error-message xml:lang="en">
      MTU value 25000 is not within range 256..9192
    </error-message>
  </rpc-error>
  <rpc-error>
    <error-type>application</error-type>
    <error-tag>invalid-value</error-tag>
    <error-severity>error</error-severity>
    <error-path xmlns:t="http://example.com/schema/1.2/config">
      /t:top/t:interface[t:name="Ethernet1/0"]/t:address/t:name
    </error-path>
    <error-message xml:lang="en">
      Invalid IP address for interface Ethernet1/0
    </error-message>
  </rpc-error>
</rpc-reply>
```

4.4. <ok> Element

The <ok> element is sent in <rpc-reply> messages if no errors or warnings occurred during the processing of an <rpc> request, and no data was returned from the operation. For example:

```
<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

4.5. Pipelining

NETCONF <rpc> requests MUST be processed serially by the managed device. Additional <rpc> requests MAY be sent before previous ones have been completed. The managed device MUST send responses only in the order the requests were received.

5. Configuration Model

NETCONF provides an initial set of operations and a number of capabilities that can be used to extend the base. NETCONF peers exchange device capabilities when the session is initiated as described in Section 8.1.

5.1. Configuration Datastores

NETCONF defines the existence of one or more configuration datastores and allows configuration operations on them. A configuration datastore is defined as the complete set of configuration data that is required to get a device from its initial default state into a desired operational state. The configuration datastore does not include state data or executive commands.

The running configuration datastore holds the complete configuration currently active on the network device. Only one configuration datastore of this type exists on the device, and it is always present. NETCONF protocol operations refer to this datastore using the <running> element.

Only the <running> configuration datastore is present in the base model. Additional configuration datastores MAY be defined by capabilities. Such configuration datastores are available only on devices that advertise the capabilities.

The capabilities in Sections 8.3 and 8.7 define the <candidate> and <startup> configuration datastores, respectively.

5.2. Data Modeling

Data modeling and content issues are outside the scope of the NETCONF protocol. An assumption is made that the device's data model is well-known to the application and that both parties are aware of issues such as the layout, containment, keying, lookup, replacement, and management of the data, as well as any other constraints imposed by the data model.

NETCONF carries configuration data inside the <config> element that is specific to device's data model. The protocol treats the contents of that element as opaque data. The device uses capabilities to announce the set of data models that the device implements. The capability definition details the operation and constraints imposed by data model.

Devices and managers can support multiple data models, including both standard and proprietary data models.

6. Subtree Filtering

6.1. Overview

XML subtree filtering is a mechanism that allows an application to select particular XML subtrees to include in the <rpc-reply> for a <get> or <get-config> operation. A small set of filters for inclusion, simple content exact-match, and selection is provided, which allows some useful, but also very limited, selection mechanisms. The server does not need to utilize any data-model-specific semantics during processing, allowing for simple and centralized implementation strategies.

Conceptually, a subtree filter is comprised of zero or more element subtrees, which represent the filter selection criteria. At each containment level within a subtree, the set of sibling nodes is logically processed by the server to determine if its subtree and path of elements to the root are included in the filter output.

Each node specified in a subtree filter represents an inclusive filter. Only associated nodes in underlying data model(s) within the specified datastore on the server are selected by the filter. A node is selected if it matches the selection criteria and hierarchy of elements given in the filter data, except that the filter absolute path name is adjusted to start from the layer below <filter>.

Response messages contain only the subtrees selected by the filter. Any selection criteria that were present in the request, within a particular selected subtree, are also included in the response. Note that some elements expressed in the filter as leaf nodes will be expanded (i.e., subtrees included) in the filter output. Specific data instances are not duplicated in the response in the event that the request contains multiple filter subtree expressions that select the same data.

6.2. Subtree Filter Components

A subtree filter is comprised of XML elements and their XML attributes. There are five types of components that can be present in a subtree filter:

- o Namespace Selection
- o Attribute Match Expressions
- o Containment Nodes

- o Selection Nodes
- o Content Match Nodes

6.2.1. Namespace Selection

A namespace is considered to match (for filter purposes) if the XML namespace associated with a particular node within the `<filter>` element is the same as in the underlying data model. Note that namespace selection cannot be used by itself. At least one element MUST be specified in the filter if any elements are to be included in the filter output.

An XML namespace wildcard mechanism is defined for subtree filtering. If an element within the `<filter>` element is not qualified by a namespace (e.g., `xmlns=""`), then the server MUST evaluate all the XML namespaces it supports, when processing that subtree filter node. This wildcard mechanism is not applicable to XML attributes.

Note that prefix values for qualified namespaces are not relevant when comparing filter elements to elements in the underlying data model.

Example:

```
<filter type="subtree">
  <top xmlns="http://example.com/schema/1.2/config"/>
</filter>
```

In this example, the `<top>` element is a selection node, and only this node in the "http://example.com/schema/1.2/config" namespace and any child nodes (from the underlying data model) will be included in the filter output.

6.2.2. Attribute Match Expressions

An attribute that appears in a subtree filter is part of an "attribute match expression". Any number of (unqualified or qualified) XML attributes MAY be present in any type of filter node. In addition to the selection criteria normally applicable to that node, the selected data MUST have matching values for every attribute specified in the node. If an element is not defined to include a specified attribute, then it is not selected in the filter output.

Example:

```
<filter type="subtree">
  <t:top xmlns:t="http://example.com/schema/1.2/config">
    <t:interfaces>
      <t:interface t:ifName="eth0"/>
    </t:interfaces>
  </t:top>
</filter>
```

In this example, the <top>, and <interfaces> elements are containment nodes, the <interface> element is a selection node, and "ifName" is an attribute match expression. Only "interface" nodes in the "http://example.com/schema/1.2/config" namespace that have an "ifName" attribute with the value "eth0" and occur within "interfaces" nodes within "top" nodes will be included in the filter output.

6.2.3. Containment Nodes

Nodes that contain child elements within a subtree filter are called "containment nodes". Each child element can be any type of node, including another containment node. For each containment node specified in a subtree filter, all data model instances that exactly match the specified namespaces, element hierarchy, and any attribute match expressions are included in the filter output.

Example:

```
<filter type="subtree">
  <top xmlns="http://example.com/schema/1.2/config">
    <users/>
  </top>
</filter>
```

In this example, the <top> element is a containment node.

6.2.4. Selection Nodes

An empty leaf node within a filter is called a "selection node", and it represents an "explicit selection" filter on the underlying data model. Presence of any selection nodes within a set of sibling nodes will cause the filter to select the specified subtree(s) and suppress automatic selection of the entire set of sibling nodes in the underlying data model. For filtering purposes, an empty leaf node can be declared either with an empty tag (e.g., <foo/>) or with explicit start and end tags (e.g., <foo> </foo>). Any whitespace characters are ignored in this form.

Example:

```
<filter type="subtree">
  <top xmlns="http://example.com/schema/1.2/config">
    <users/>
  </top>
</filter>
```

In this example, the `<top>` element is a containment node, and the `<users>` element is a selection node. Only "users" nodes in the "http://example.com/schema/1.2/config" namespace that occur within a `<top>` element that is the root of the configuration datastore will be included in the filter output.

6.2.5. Content Match Nodes

A leaf node that contains simple content is called a "content match node". It is used to select some or all of its sibling nodes for filter output, and it represents an exact-match filter on the leaf node element content. The following constraints apply to content match nodes:

- o A content match node MUST NOT contain nested elements.
- o Multiple content match nodes (i.e., sibling nodes) are logically combined in an "AND" expression.
- o Filtering of mixed content is not supported.
- o Filtering of list content is not supported.
- o Filtering of whitespace-only content is not supported.
- o A content match node MUST contain non-whitespace characters. An empty element (e.g., `<foo></foo>`) will be interpreted as a selection node (e.g., `<foo/>`).
- o Leading and trailing whitespace characters are ignored, but any whitespace characters within a block of text characters are not ignored or modified.

If all specified sibling content match nodes in a subtree filter expression are "true", then the filter output nodes are selected in the following manner:

- o Each content match node in the sibling set is included in the filter output.
- o If any containment nodes are present in the sibling set, then they are processed further and included if any nested filter criteria

are also met.

- o If any selection nodes are present in the sibling set, then all of them are included in the filter output.
- o If any sibling nodes of the selection node are instance identifier components for a conceptual data structure (e.g., list key leaf), then they MAY also be included in the filter output.
- o Otherwise (i.e., there are no selection or containment nodes in the filter sibling set), all the nodes defined at this level in the underlying data model (and their subtrees, if any) are returned in the filter output.

If any of the sibling content match node tests are "false", then no further filter processing is performed on that sibling set, and none of the sibling subtrees are selected by the filter, including the content match node(s).

Example:

```
<filter type="subtree">
  <top xmlns="http://example.com/schema/1.2/config">
    <users>
      <user>
        <name>fred</name>
      </user>
    </users>
  </top>
</filter>
```

In this example, the <users> and <user> nodes are both containment nodes, and <name> is a content match node. Since no sibling nodes of <name> are specified (and therefore no containment or selection nodes), all of the sibling nodes of <name> are returned in the filter output. Only "user" nodes in the "http://example.com/schema/1.2/config" namespace that match the element hierarchy and for which the <name> element is equal to "fred" will be included in the filter output.

6.3. Subtree Filter Processing

The filter output (the set of selected nodes) is initially empty.

Each subtree filter can contain one or more data model fragments, which represent portions of the data model that will be selected (with all child nodes) in the filter output.

Each subtree data fragment is compared by the server to the internal data models supported by the server. If the entire subtree data-fragment filter (starting from the root to the innermost element specified in the filter) exactly matches a corresponding portion of the supported data model, then that node and all its children are included in the result data.

The server processes all nodes with the same parent node (sibling set) together, starting from the root to the leaf nodes. The root elements in the filter are considered in the same sibling set (assuming they are in the same namespace), even though they do not have a common parent.

For each sibling set, the server determines which nodes are included (or potentially included) in the filter output, and which sibling subtrees are excluded (pruned) from the filter output. The server first determines which types of nodes are present in the sibling set and processes the nodes according to the rules for their type. If any nodes in the sibling set are selected, then the process is recursively applied to the sibling sets of each selected node. The algorithm continues until all sibling sets in all subtrees specified in the filter have been processed.

6.4. Subtree Filtering Examples

6.4.1. No Filter

Leaving out the filter on the <get> operation returns the entire data model.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get/>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <!-- ... entire set of data returned ... -->
  </data>
</rpc-reply>
```

6.4.2. Empty Filter

An empty filter will select nothing because no content match or selection nodes are present. This is not an error. The <filter> element's "type" attribute used in these examples is discussed further in Section 7.1.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
    </filter>
  </get>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
  </data>
</rpc-reply>
```

6.4.3. Select the Entire <users> Subtree

The filter in this example contains one selection node (<users>), so just that subtree is selected by the filter. This example represents the fully-populated <users> data model in most of the filter examples that follow. In a real data model, the <company-info> would not likely be returned with the list of users for a particular host or network.

NOTE: The filtering and configuration examples used in this document appear in the namespace "http://example.com/schema/1.2/config". The root element of this namespace is <top>. The <top> element and its descendents represent an example configuration data model only.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://example.com/schema/1.2/config">
        <users/>
      </top>
    </filter>
  </get-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <top xmlns="http://example.com/schema/1.2/config">
      <users>
```

```
<user>
  <name>root</name>
  <type>superuser</type>
  <full-name>Charlie Root</full-name>
  <company-info>
    <dept>1</dept>
    <id>1</id>
  </company-info>
</user>
<user>
  <name>fred</name>
  <type>admin</type>
  <full-name>Fred Flintstone</full-name>
  <company-info>
    <dept>2</dept>
    <id>2</id>
  </company-info>
</user>
<user>
  <name>barney</name>
  <type>admin</type>
  <full-name>Barney Rubble</full-name>
  <company-info>
    <dept>2</dept>
    <id>3</id>
  </company-info>
</user>
</users>
</top>
</data>
</rpc-reply>
```

The following filter request would have produced the same result, but only because the container `<users>` defines one child element (`<user>`).

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://example.com/schema/1.2/config">
        <users>
          <user/>
        </users>
      </top>
    </filter>
  </get-config>
</rpc>
```

6.4.4. Select All <name> Elements within the <users> Subtree

This filter contains two containment nodes (<users>, <user>) and one selection node (<name>). All instances of the <name> element in the same sibling set are selected in the filter output. The client might need to know that <name> is used as an instance identifier in this particular data structure, but the server does not need to know that meta-data in order to process the request.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://example.com/schema/1.2/config">
        <users>
          <user>
            <name/>
          </user>
        </users>
      </top>
    </filter>
  </get-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <top xmlns="http://example.com/schema/1.2/config">
      <users>
        <user>
          <name>root</name>
        </user>
        <user>
          <name>fred</name>
        </user>
        <user>
          <name>barney</name>
        </user>
      </users>
    </top>
  </data>
</rpc-reply>
```

6.4.5. One Specific <user> Entry

This filter contains two containment nodes (<users>, <user>) and one content match node (<name>). All instances of the sibling set containing <name> for which the value of <name> equals "fred" are selected in the filter output.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://example.com/schema/1.2/config">
        <users>
          <user>
            <name>fred</name>
          </user>
        </users>
      </top>
    </filter>
  </get-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <top xmlns="http://example.com/schema/1.2/config">
      <users>
        <user>
          <name>fred</name>
          <type>admin</type>
          <full-name>Fred Flintstone</full-name>
          <company-info>
            <dept>2</dept>
            <id>2</id>
          </company-info>
        </user>
      </users>
    </top>
  </data>
</rpc-reply>
```

6.4.6. Specific Elements from a Specific <user> Entry

This filter contains two containment nodes (<users>, <user>), one content match node (<name>), and two selection nodes (<type>, <full-name>). All instances of the <type> and <full-name> elements in the same sibling set containing <name> for which the value of <name> equals "fred" are selected in the filter output. The <company-info> element is not included because the sibling set contains selection nodes.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://example.com/schema/1.2/config">
        <users>
          <user>
            <name>fred</name>
            <type/>
            <full-name/>
          </user>
        </users>
      </top>
    </filter>
  </get-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <top xmlns="http://example.com/schema/1.2/config">
      <users>
        <user>
          <name>fred</name>
          <type>admin</type>
          <full-name>Fred Flintstone</full-name>
        </user>
      </users>
    </top>
  </data>
</rpc-reply>
```

6.4.7. Multiple Subtrees

This filter contains three subtrees (name=root, fred, barney).

The "root" subtree filter contains two containment nodes (<users>, <user>), one content match node (<name>), and one selection node (<company-info>). The subtree selection criteria is met, and just the company-info subtree for "root" is selected in the filter output.

The "fred" subtree filter contains three containment nodes (<users>, <user>, <company-info>), one content match node (<name>), and one selection node (<id>). The subtree selection criteria is met, and just the <id> element within the company-info subtree for "fred" is

selected in the filter output.

The "barney" subtree filter contains three containment nodes (<users>, <user>, <company-info>), two content match nodes (<name>, <type>), and one selection node (<dept>). The subtree selection criteria is not met because user "barney" is not a "superuser", and the entire subtree for "barney" (including its parent <user> entry) is excluded from the filter output.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://example.com/schema/1.2/config">
        <users>
          <user>
            <name>root</name>
            <company-info/>
          </user>
          <user>
            <name>fred</name>
            <company-info>
              <id/>
            </company-info>
          </user>
          <user>
            <name>barney</name>
            <type>superuser</type>
            <company-info>
              <dept/>
            </company-info>
          </user>
        </users>
      </top>
    </filter>
  </get-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <top xmlns="http://example.com/schema/1.2/config">
      <users>
        <user>
          <name>root</name>
```

```
      <company-info>
        <dept>1</dept>
        <id>1</id>
      </company-info>
    </user>
    <user>
      <name>fred</name>
      <company-info>
        <id>2</id>
      </company-info>
    </user>
  </users>
</top>
</data>
</rpc-reply>
```

6.4.8. Elements with Attribute Naming

In this example, the filter contains one containment node (<interfaces>), one attribute match expression ("ifName"), and one selection node (<interface>). All instances of the <interface> subtree that have an "ifName" attribute equal to "eth0" are selected in the filter output. The filter data elements and attributes are qualified because the "ifName" attribute will not be considered part of the "schema/1.2" namespace if it is unqualified.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <t:top xmlns:t="http://example.com/schema/1.2/stats">
        <t:interfaces>
          <t:interface t:ifName="eth0"/>
        </t:interfaces>
      </t:top>
    </filter>
  </get>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <t:top xmlns:t="http://example.com/schema/1.2/stats">
      <t:interfaces>
        <t:interface t:ifName="eth0">
          <t:ifInOctets>45621</t:ifInOctets>
          <t:ifOutOctets>774344</t:ifOutOctets>
        </t:interface>
      </t:interfaces>
    </t:top>
  </data>
</rpc-reply>
```

If "ifName" were a child node instead of an attribute, then the following request would produce similar results.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://example.com/schema/1.2/stats">
        <interfaces>
          <interface>
            <ifName>eth0</ifName>
          </interface>
        </interfaces>
      </top>
    </filter>
  </get>
</rpc>
```

7. Protocol Operations

The NETCONF protocol provides a small set of low-level operations to manage device configurations and retrieve device state information. The base protocol provides operations to retrieve, configure, copy, and delete configuration datastores. Additional operations are provided, based on the capabilities advertised by the device.

The base protocol includes the following protocol operations:

- o get
- o get-config
- o edit-config
- o copy-config
- o delete-config
- o lock
- o unlock
- o close-session
- o kill-session

A protocol operation can fail for various reasons, including "operation not supported". An initiator SHOULD NOT assume that any operation will always succeed. The return values in any RPC reply SHOULD be checked for error responses.

The syntax and XML encoding of the protocol operations are formally defined in the YANG module in Appendix C. The following sections describe the semantics of each protocol operation.

7.1. <get-config>

Description:

Retrieve all or part of a specified configuration datastore.

Parameters:

source:

Name of the configuration datastore being queried, such as `<running/>`.

filter:

This parameter identifies the portions of the device configuration datastore to retrieve. If this parameter is not present, the entire configuration is returned.

The `<filter>` element MAY optionally contain a "type" attribute. This attribute indicates the type of filtering syntax used within the `<filter>` element. The default filtering mechanism in NETCONF is referred to as subtree filtering and is described in Section 6. The value "subtree" explicitly identifies this type of filtering.

If the NETCONF peer supports the `:xpath` capability (Section 8.9), the value "xpath" MAY be used to indicate that the "select" attribute on the `<filter>` element contains an XPath expression.

Positive Response:

If the device can satisfy the request, the server sends an `<rpc-reply>` element containing a `<data>` element with the results of the query.

Negative Response:

An `<rpc-error>` element is included in the `<rpc-reply>` if the request cannot be completed for any reason.

Example: To retrieve the entire `<users>` subtree:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://example.com/schema/1.2/config">
        <users/>
      </top>
    </filter>
  </get-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <top xmlns="http://example.com/schema/1.2/config">
      <users>
        <user>
          <name>root</name>
          <type>superuser</type>
          <full-name>Charlie Root</full-name>
          <company-info>
            <dept>1</dept>
            <id>1</id>
          </company-info>
        </user>
        <!-- additional <user> elements appear here... -->
      </users>
    </top>
  </data>
</rpc-reply>
```

Section 6 contains additional examples of subtree filtering.

7.2. <edit-config>

Description:

The <edit-config> operation loads all or part of a specified configuration to the specified target configuration datastore. This operation allows the new configuration to be expressed in several ways, such as using a local file, a remote file, or inline. If the target configuration datastore does not exist, it will be created.

If a NETCONF peer supports the :url capability (Section 8.8), the

<url> element can appear instead of the <config> parameter.

The device analyzes the source and target configurations and performs the requested changes. The target configuration is not necessarily replaced, as with the <copy-config> message. Instead, the target configuration is changed in accordance with the source's data and requested operations.

If the <edit-config> operation contains multiple sub-operations which apply to the same conceptual node in the underlying data model, then the result of the operation is undefined (i.e., outside the scope of the NETCONF protocol).

Attributes:

operation:

Elements in the <config> subtree MAY contain an "operation" attribute. The attribute identifies the point in the configuration to perform the operation and MAY appear on multiple elements throughout the <config> subtree.

If the "operation" attribute is not specified, the configuration is merged into the configuration datastore.

The "operation" attribute has one of the following values:

merge: The configuration data identified by the element containing this attribute is merged with the configuration at the corresponding level in the configuration datastore identified by the <target> parameter. This is the default behavior.

replace: The configuration data identified by the element containing this attribute replaces any related configuration in the configuration datastore identified by the <target> parameter. If no such configuration data exists in the configuration datastore, it is created. Unlike a <copy-config> operation, which replaces the entire target configuration, only the configuration actually present in the <config> parameter is affected.

create: The configuration data identified by the element containing this attribute is added to the configuration if and only if the configuration data does not already exist in the configuration datastore. If the configuration data exists, an <rpc-error> element is returned with an <error-tag> value of "data-exists".

delete: The configuration data identified by the element containing this attribute is deleted from the configuration if and only if the configuration data currently exists in the configuration datastore. If the configuration data does not exist, an `<rpc-error>` element is returned with an `<error-tag>` value of "data-missing".

remove: The configuration data identified by the element containing this attribute is deleted from the configuration if the configuration data currently exists in the configuration datastore. If the configuration data does not exist, the "remove" operation is silently ignored by the server.

Parameters:

target:

Name of the configuration datastore being edited, such as `<running/>` or `<candidate/>`.

default-operation:

Selects the default operation (as described in the "operation" attribute) for this `<edit-config>` request. The default value for the `<default-operation>` parameter is "merge".

The `<default-operation>` parameter is optional, but if provided, it has one of the following values:

merge: The configuration data in the `<config>` parameter is merged with the configuration at the corresponding level in the target datastore. This is the default behavior.

replace: The configuration data in the `<config>` parameter completely replaces the configuration in the target datastore. This is useful for loading previously saved configuration data.

none: The target datastore is unaffected by the configuration in the `<config>` parameter, unless and until the incoming configuration data uses the "operation" attribute to request a different operation. If the configuration in the `<config>` parameter contains data for which there is not a corresponding level in the target datastore, an `<rpc-error>` is returned with an `<error-tag>` value of data-missing. Using "none" allows operations like "delete" to avoid unintentionally creating the parent hierarchy of the element

to be deleted.

test-option:

The <test-option> element MAY be specified only if the device advertises the :validate:1.1 capability (Section 8.6).

The <test-option> element has one of the following values:

test-then-set: Perform a validation test before attempting to set. If validation errors occur, do not perform the <edit-config> operation. This is the default test-option.

set: Perform a set without a validation test first.

test-only: Perform only the validation test, without attempting to set.

error-option:

The <error-option> element has one of the following values:

stop-on-error: Abort the edit-config operation on first error. This is the default error-option.

continue-on-error: Continue to process configuration data on error; error is recorded, and negative response is generated if any errors occur.

rollback-on-error: If an error condition occurs such that an error severity <rpc-error> element is generated, the server will stop processing the edit-config operation and restore the specified configuration to its complete state at the start of this edit-config operation. This option requires the server to support the :rollback-on-error capability described in Section 8.5.

config:

A hierarchy of configuration data as defined by one of the device's data models. The contents MUST be placed in an appropriate namespace, to allow the device to detect the appropriate data model, and the contents MUST follow the constraints of that data model, as defined by its capability definition. Capabilities are discussed in Section 8.

Positive Response:

If the device was able to satisfy the request, an `<rpc-reply>` is sent containing an `<ok>` element.

Negative Response:

An `<rpc-error>` response is sent if the request cannot be completed for any reason.

Example:

The `<edit-config>` examples in this section utilize a simple data model, in which multiple instances of the `<interface>` element can be present, and an instance is distinguished by the `<name>` element within each `<interface>` element.

Set the MTU to 1500 on an interface named "Ethernet0/0" in the running configuration:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config>
      <top xmlns="http://example.com/schema/1.2/config">
        <interface>
          <name>Ethernet0/0</name>
          <mtu>1500</mtu>
        </interface>
      </top>
    </config>
  </edit-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

Add an interface named "Ethernet0/0" to the running configuration, replacing any previous interface with that name:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://example.com/schema/1.2/config">
        <interface xc:operation="replace">
          <name>Ethernet0/0</name>
          <mtu>1500</mtu>
          <address>
            <name>192.0.2.4</name>
            <prefix-length>24</prefix-length>
          </address>
        </interface>
      </top>
    </config>
  </edit-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

Delete the configuration for an interface named "Ethernet0/0" from the running configuration:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <default-operation>none</default-operation>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://example.com/schema/1.2/config">
        <interface xc:operation="delete">
          <name>Ethernet0/0</name>
        </interface>
      </top>
    </config>
  </edit-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

Delete interface 192.0.2.4 from an OSPF area (other interfaces configured in the same area are unaffected):

```

<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <default-operation>none</default-operation>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://example.com/schema/1.2/config">
        <protocols>
          <ospf>
            <area>
              <name>0.0.0.0</name>
              <interfaces>
                <interface xc:operation="delete">
                  <name>192.0.2.4</name>
                </interface>
              </interfaces>
            </area>
          </ospf>
        </protocols>
      </top>
    </config>
  </edit-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>

```

7.3. <copy-config>

Description:

Create or replace an entire configuration datastore with the contents of another complete configuration datastore. If the target datastore exists, it is overwritten. Otherwise, a new one is created, if allowed.

If a NETCONF peer supports the :url capability (Section 8.8), the <url> element can appear as the <source> or <target> parameter.

Even if it advertises the :writable-running capability, a device MAY choose not to support the <running/> configuration datastore as the <target> parameter of a <copy-config> operation. A device MAY choose not to support remote-to-remote copy operations, where both the <source> and <target> parameters use the <url> element.

If the <source> and <target> parameters identify the same URL or configuration datastore, an error MUST be returned with an error-tag containing "invalid-value".

Parameters:

target:

Name of the configuration datastore to use as the destination of the <copy-config> operation.

source:

Name of the configuration datastore to use as the source of the <copy-config> operation, or the <config> element containing the complete configuration to copy.

Positive Response:

If the device was able to satisfy the request, an <rpc-reply> is sent that includes an <ok> element.

Negative Response:

An <rpc-error> element is included within the <rpc-reply> if the request cannot be completed for any reason.

Example:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <copy-config>
    <target>
      <running/>
    </target>
    <source>
      <url>https://user:password@example.com/cfg/new.txt</url>
    </source>
  </copy-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

7.4. <delete-config>

Description:

Delete a configuration datastore. The <running> configuration datastore cannot be deleted.

If a NETCONF peer supports the :url capability (Section 8.8), the <url> element can appear as the <target> parameter.

Parameters:

target:

Name of the configuration datastore to delete.

Positive Response:

If the device was able to satisfy the request, an <rpc-reply> is sent that includes an <ok> element.

Negative Response:

An <rpc-error> element is included within the <rpc-reply> if the request cannot be completed for any reason.

Example:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <delete-config>
    <target>
      <startup/>
    </target>
  </delete-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

7.5. <lock>

Description:

The <lock> operation allows the client to lock the entire configuration datastore system of a device. Such locks are intended to be short-lived and allow a client to make a change without fear of interaction with other NETCONF clients, non-NETCONF clients (e.g., SNMP and command line interface (CLI) scripts), and human users.

An attempt to lock the configuration datastore MUST fail if an existing session or other entity holds a lock on any portion of the lock target.

When the lock is acquired, the server MUST prevent any changes to the locked resource other than those requested by this session. SNMP and CLI requests to modify the resource MUST fail with an appropriate error.

The duration of the lock is defined as beginning when the lock is acquired and lasting until either the lock is released or the NETCONF session closes. The session closure can be explicitly performed by the client, or implicitly performed by the server based on criteria such as failure of the underlying transport, simple inactivity timeout, or detection of abusive behavior on the part of the client. This criteria is dependent on the implementation and the underlying transport.

The <lock> operation takes a mandatory parameter, <target>. The <target> parameter names the configuration datastore that will be locked. When a lock is active, using the <edit-config> operation on the locked configuration datastore and using the locked configuration as a target of the <copy-config> operation will be disallowed by any other NETCONF session. Additionally, the system will ensure that these locked configuration resources will not be modified by other non-NETCONF management operations such as SNMP and CLI. The <kill-session> operation can be used to force the release of a lock owned by another NETCONF session. It is beyond the scope of this document to define how to break locks held by other entities.

A lock MUST NOT be granted if either of the following conditions is true:

- * A lock is already held by any NETCONF session or another entity.
- * The target configuration is <candidate>, it has already been modified, and these changes have not been committed or rolled

back.

The server MUST respond with either an <ok> element or an <rpc-error>.

A lock will be released by the system if the session holding the lock is terminated for any reason.

Parameters:

target:

Name of the configuration datastore to lock.

Positive Response:

If the device was able to satisfy the request, an <rpc-reply> is sent that contains an <ok> element.

Negative Response:

An <rpc-error> element is included in the <rpc-reply> if the request cannot be completed for any reason.

If the lock is already held, the <error-tag> element will be "lock-denied" and the <error-info> element will include the <session-id> of the lock owner. If the lock is held by a non-NETCONF entity, a <session-id> of 0 (zero) is included. Note that any other entity performing a lock on even a partial piece of a target will prevent a NETCONF lock (which is global) from being obtained on that target.

Example:

The following example shows a successful acquisition of a lock.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <lock>
    <target>
      <running/>
    </target>
  </lock>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/> <!-- lock succeeded -->
```

```
</rpc-reply>
```

Example:

The following example shows a failed attempt to acquire a lock when the lock is already in use.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <lock>
    <target>
      <running/>
    </target>
  </lock>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <rpc-error> <!-- lock failed -->
    <error-type>protocol</error-type>
    <error-tag>lock-denied</error-tag>
    <error-severity>error</error-severity>
    <error-message>
      Lock failed, lock is already held
    </error-message>
    <error-info>
      <session-id>454</session-id>
      <!-- lock is held by NETCONF session 454 -->
    </error-info>
  </rpc-error>
</rpc-reply>
```

7.6. <unlock>

Description:

The <unlock> operation is used to release a configuration lock, previously obtained with the <lock> operation.

An <unlock> operation will not succeed if any of the following conditions are true:

- * the specified lock is not currently active
- * the session issuing the <unlock> operation is not the same session that obtained the lock

The server MUST respond with either an <ok> element or an <rpc-error>.

Parameters:

target:

Name of the configuration datastore to unlock.

A NETCONF client is not permitted to unlock a configuration datastore that it did not lock.

Positive Response:

If the device was able to satisfy the request, an <rpc-reply> is sent that contains an <ok> element.

Negative Response:

An <rpc-error> element is included in the <rpc-reply> if the request cannot be completed for any reason.

Example:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <unlock>
    <target>
      <running/>
    </target>
  </unlock>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

7.7. <get>

Description:

Retrieve running configuration and device state information.

Parameters:

filter:

This parameter specifies the portion of the system configuration and state data to retrieve. If this parameter is not present, all the device configuration and state information is returned.

The <filter> element MAY optionally contain a "type" attribute. This attribute indicates the type of filtering syntax used within the <filter> element. The default filtering mechanism in NETCONF is referred to as subtree filtering and is described in Section 6. The value "subtree" explicitly identifies this type of filtering.

If the NETCONF peer supports the :xpath capability (Section 8.9), the value "xpath" MAY be used to indicate that the "select" attribute of the <filter> element contains an XPath expression.

Positive Response:

If the device was able to satisfy the request, an <rpc-reply> is sent. The <data> section contains the appropriate subset.

Negative Response:

An <rpc-error> element is included in the <rpc-reply> if the request cannot be completed for any reason.

Example:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://example.com/schema/1.2/stats">
        <interfaces>
          <interface>
            <ifName>eth0</ifName>
          </interface>
        </interfaces>
      </top>
    </filter>
  </get>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <top xmlns="http://example.com/schema/1.2/stats">
      <interfaces>
        <interface>
          <ifName>eth0</ifName>
          <ifInOctets>45621</ifInOctets>
          <ifOutOctets>774344</ifOutOctets>
        </interface>
      </interfaces>
    </top>
  </data>
</rpc-reply>
```

7.8. <close-session>

Description:

Request graceful termination of a NETCONF session.

When a NETCONF server receives a <close-session> request, it will gracefully close the session. The server will release any locks and resources associated with the session and gracefully close any associated connections. Any NETCONF requests received after a <close-session> request will be ignored.

Positive Response:

If the device was able to satisfy the request, an <rpc-reply> is sent that includes an <ok> element.

Negative Response:

An `<rpc-error>` element is included in the `<rpc-reply>` if the request cannot be completed for any reason.

Example:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <close-session/>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

7.9. `<kill-session>`

Description:

Force the termination of a NETCONF session.

When a NETCONF entity receives a `<kill-session>` request for an open session, it will abort any operations currently in process, release any locks and resources associated with the session, and close any associated connections.

If a NETCONF server receives a `<kill-session>` request while processing a confirmed commit (Section 8.4), it MUST restore the configuration to its state before the confirmed commit was issued.

Otherwise, the `<kill-session>` operation does not roll back configuration or other device state modifications made by the entity holding the lock.

Parameters:

session-id:

Session identifier of the NETCONF session to be terminated. If this value is equal to the current session ID, an "invalid-value" error is returned.

Positive Response:

If the device was able to satisfy the request, an <rpc-reply> is sent that includes an <ok> element.

Negative Response:

An <rpc-error> element is included in the <rpc-reply> if the request cannot be completed for any reason.

Example:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>4</session-id>
  </kill-session>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

8. Capabilities

This section defines a set of capabilities that a client or a server MAY implement. Each peer advertises its capabilities by sending them during an initial capabilities exchange. Each peer needs to understand only those capabilities that it might use and MUST ignore any capability received from the other peer that it does not require or does not understand.

Additional capabilities can be defined using the template in Appendix D. Future capability definitions can be published as standards by standards bodies or published as proprietary extensions.

A NETCONF capability is identified with a URI. The base capabilities are defined using URNs following the method described in RFC 3553 [RFC3553]. Capabilities defined in this document have the following format:

```
urn:ietf:params:netconf:capability:{name}:1.x
```

where {name} is the name of the capability. Capabilities are often referenced in discussions and email using the shorthand `:{name}`, or `:{name}:{version}` if the capability exists in multiple versions. For example, the foo capability would have the formal name "urn:ietf:params:netconf:capability:foo:1.0" and be called `":foo"`. The shorthand form MUST NOT be used inside the protocol.

8.1. Capabilities Exchange

Capabilities are advertised in messages sent by each peer during session establishment. When the NETCONF session is opened, each peer (both client and server) MUST send a <hello> element containing a list of that peer's capabilities. Each peer MUST send at least the base NETCONF capability, "urn:ietf:params:netconf:base:1.1". A peer MAY include capabilities for previous NETCONF versions, to indicate that it supports multiple protocol versions.

Both NETCONF peers MUST verify that the other peer has advertised a common protocol version. When comparing protocol version capability URIs, only the base part is used, in the event any parameters are encoded at the end of the URI string. If no protocol version capability in common is found, the NETCONF peer MUST NOT continue the session. If more than one protocol version URI in common is present, then the highest numbered (most recent) protocol version MUST be used by both peers.

A server sending the <hello> element MUST include a <session-id> element containing the session ID for this NETCONF session. A client

sending the <hello> element MUST NOT include a <session-id> element.

A server receiving a <hello> message with a <session-id> element MUST terminate the NETCONF session. Similarly, a client that does not receive a <session-id> element in the server's <hello> message MUST terminate the NETCONF session (without first sending a <close-session>).

In the following example, a server advertises the base NETCONF capability, one NETCONF capability defined in the base NETCONF document, and one implementation-specific capability.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
      urn:ietf:params:netconf:base:1.1
    </capability>
    <capability>
      urn:ietf:params:netconf:capability:startup:1.0
    </capability>
    <capability>
      http://example.net/router/2.3/myfeature
    </capability>
  </capabilities>
  <session-id>4</session-id>
</hello>
```

Each peer sends its <hello> element simultaneously as soon as the connection is open. A peer MUST NOT wait to receive the capability set from the other side before sending its own set.

8.2. Writable-Running Capability

8.2.1. Description

The :writable-running capability indicates that the device supports direct writes to the <running> configuration datastore. In other words, the device supports <edit-config> and <copy-config> operations where the <running> configuration is the target.

8.2.2. Dependencies

None.

8.2.3. Capability Identifier

The :writable-running capability is identified by the following capability string:

urn:ietf:params:netconf:capability:writable-running:1.0

8.2.4. New Operations

None.

8.2.5. Modifications to Existing Operations

8.2.5.1. <edit-config>

The :writable-running capability modifies the <edit-config> operation to accept the <running> element as a <target>.

8.2.5.2. <copy-config>

The :writable-running capability modifies the <copy-config> operation to accept the <running> element as a <target>.

8.3. Candidate Configuration Capability

8.3.1. Description

The candidate configuration capability, :candidate, indicates that the device supports a candidate configuration datastore, which is used to hold configuration data that can be manipulated without impacting the device's current configuration. The candidate configuration is a full configuration data set that serves as a work place for creating and manipulating configuration data. Additions, deletions, and changes can be made to this data to construct the desired configuration data. A <commit> operation MAY be performed at any time that causes the device's running configuration to be set to the value of the candidate configuration.

The <commit> operation effectively sets the running configuration to the current contents of the candidate configuration. While it could be modeled as a simple copy, it is done as a distinct operation for a number of reasons. In keeping high-level concepts as first class operations, we allow developers to see more clearly both what the client is requesting and what the server must perform. This keeps the intentions more obvious, the special cases less complex, and the interactions between operations more straightforward. For example, the :confirmed-commit:1.1 capability (Section 8.4) would make no sense as a "copy confirmed" operation.

The candidate configuration can be shared among multiple sessions. Unless a client has specific information that the candidate configuration is not shared, it MUST assume that other sessions are able to modify the candidate configuration at the same time. It is

therefore prudent for a client to lock the candidate configuration before modifying it.

The client can discard any uncommitted changes to the candidate configuration by executing the <discard-changes> operation. This operation reverts the contents of the candidate configuration to the contents of the running configuration.

8.3.2. Dependencies

None.

8.3.3. Capability Identifier

The :candidate capability is identified by the following capability string:

urn:ietf:params:netconf:capability:candidate:1.0

8.3.4. New Operations

8.3.4.1. <commit>

Description:

When a candidate configuration's content is complete, the configuration data can be committed, publishing the data set to the rest of the device and requesting the device to conform to the behavior described in the new configuration.

To commit the candidate configuration as the device's new current configuration, use the <commit> operation.

The <commit> operation instructs the device to implement the configuration data contained in the candidate configuration. If the device is unable to commit all of the changes in the candidate configuration datastore, then the running configuration MUST remain unchanged. If the device does succeed in committing, the running configuration MUST be updated with the contents of the candidate configuration.

If the running or candidate configuration is currently locked by a different session, the <commit> operation MUST fail with an <error-tag> value of "in-use".

If the system does not have the :candidate capability, the <commit> operation is not available.

Positive Response:

If the device was able to satisfy the request, an `<rpc-reply>` is sent that contains an `<ok>` element.

Negative Response:

An `<rpc-error>` element is included in the `<rpc-reply>` if the request cannot be completed for any reason.

Example:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <commit/>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

8.3.4.2. `<discard-changes>`

If the client decides that the candidate configuration is not to be committed, the `<discard-changes>` operation can be used to revert the candidate configuration to the current running configuration.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <discard-changes/>
</rpc>
```

This operation discards any uncommitted changes by resetting the candidate configuration with the content of the running configuration.

8.3.5. Modifications to Existing Operations

8.3.5.1. `<get-config>`, `<edit-config>`, `<copy-config>`, and `<validate>`

The candidate configuration can be used as a source or target of any `<get-config>`, `<edit-config>`, `<copy-config>`, or `<validate>` operation as a `<source>` or `<target>` parameter. The `<candidate>` element is used to indicate the candidate configuration:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <candidate/>
    </source>
  </get-config>
</rpc>
```

8.3.5.2. <lock> and <unlock>

The candidate configuration can be locked using the <lock> operation with the <candidate> element as the <target> parameter:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <lock>
    <target>
      <candidate/>
    </target>
  </lock>
</rpc>
```

Similarly, the candidate configuration is unlocked using the <candidate> element as the <target> parameter:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <unlock>
    <target>
      <candidate/>
    </target>
  </unlock>
</rpc>
```

When a client fails with outstanding changes to the candidate configuration, recovery can be difficult. To facilitate easy recovery, any outstanding changes are discarded when the lock is released, whether explicitly with the <unlock> operation or implicitly from session failure.

8.4. Confirmed Commit Capability

8.4.1. Description

The :confirmed-commit:1.1 capability indicates that the server will support the <cancel-commit> operation and the <confirmed>, <confirm-timeout>, <persist>, and <persist-id> parameters for the

<commit> operation. See Section 8.3 for further details on the <commit> operation.

A confirmed commit operation MUST be reverted if a confirming commit is not issued within the timeout period (by default 600 seconds = 10 minutes). The confirming commit is a <commit> operation without the <confirmed> parameter. The timeout period can be adjusted with the <confirm-timeout> parameter. If a follow-up confirmed commit operation is issued before the timer expires, the timer is reset to the new value (600 seconds by default). Both the confirming commit and a follow-up confirmed commit operation MAY introduce additional changes to the configuration.

If the <persist> element is not given in the confirmed commit operation, any follow-up commit and the confirming commit MUST be issued on the same session that issued the confirmed commit. If the <persist> element is given in the confirmed commit operation, a follow-up commit and the confirming commit can be given on any session, and they MUST include a <persist-id> element with a value equal to the given value of the <persist> element.

If the server also advertises the :startup capability, a <copy-config> from running to startup is also necessary to save the changes to startup.

If the session issuing the confirmed commit is terminated for any reason before the confirm timeout expires, the server MUST restore the configuration to its state before the confirmed commit was issued, unless the confirmed commit also included a <persist> element.

If the device reboots for any reason before the confirm timeout expires, the server MUST restore the configuration to its state before the confirmed commit was issued.

If a confirming commit is not issued, the device will revert its configuration to the state prior to the issuance of the confirmed commit. To cancel a confirmed commit and revert changes without waiting for the confirm timeout to expire, the client can explicitly restore the configuration to its state before the confirmed commit was issued, by using the <cancel-commit> operation.

For shared configurations, this feature can cause other configuration changes (for example, via other NETCONF sessions) to be inadvertently altered or removed, unless the configuration locking feature is used (in other words, the lock is obtained before the <edit-config> operation is started). Therefore, it is strongly suggested that in order to use this feature with shared configuration datastores,

configuration locking SHOULD also be used.

Version 1.0 of this capability was defined in [RFC4741]. Version 1.1 is defined in this document, and extends version 1.0 by adding a new operation, <cancel-commit>, and two new optional parameters, <persist> and <persist-id>. For backwards compatibility with old clients, servers confirming to this specification MAY advertise version 1.0 in addition to version 1.1.

8.4.2. Dependencies

The :confirmed-commit:1.1 capability is only relevant if the :candidate capability is also supported.

8.4.3. Capability Identifier

The :confirmed-commit:1.1 capability is identified by the following capability string:

urn:ietf:params:netconf:capability:confirmed-commit:1.1

8.4.4. New Operations

8.4.4.1. <cancel-commit>

Description:

Cancels an ongoing confirmed commit. If the <persist-id> parameter is not given, the <cancel-commit> operation MUST be issued on the same session that issued the confirmed commit.

Parameters:

persist-id:

Cancels a persistent confirmed commit. The value MUST be equal to the value given in the <persist> parameter to the <commit> operation. If the value does not match, the operation fails with an "invalid-value" error.

Positive Response:

If the device was able to satisfy the request, an <rpc-reply> is sent that contains an <ok> element.

Negative Response:

An <rpc-error> element is included in the <rpc-reply> if the request cannot be completed for any reason.

Example:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <commit>
    <confirmed/>
  </commit>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>

<rpc message-id="102"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <cancel-commit/>
</rpc>

<rpc-reply message-id="102"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

8.4.5. Modifications to Existing Operations

8.4.5.1. <commit>

The :confirmed-commit:1.1 capability allows 4 additional parameters to the <commit> operation.

Parameters:

confirmed:

Perform a confirmed commit operation.

confirm-timeout:

Timeout period for confirmed commit, in seconds. If unspecified, the confirm timeout defaults to 600 seconds.

persist:

Make the confirmed commit survive a session termination, and set a token on the ongoing confirmed commit.

persist-id:

Used to issue a follow-up confirmed commit or a confirming commit from any session, with the token from the previous commit operation.

Example:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <commit>
    <confirmed/>
    <confirm-timeout>120</confirm-timeout>
  </commit>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

Example:

```
<!-- start a persistent confirmed-commit -->
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <commit>
    <confirmed/>
    <persist>IQ,d4668</persist>
  </commit>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>

<!-- confirm the persistent confirmed-commit,
possibly from another session -->
<rpc message-id="102"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <commit>
    <persist-id>IQ,d4668</persist-id>
  </commit>
</rpc>

<rpc-reply message-id="102"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

8.5. Rollback on Error Capability

8.5.1. Description

This capability indicates that the server will support the "rollback-on-error" value in the <error-option> parameter to the <edit-config> operation.

For shared configurations, this feature can cause other configuration changes (for example, via other NETCONF sessions) to be inadvertently altered or removed, unless the configuration locking feature is used (in other words, the lock is obtained before the <edit-config> operation is started). Therefore, it is strongly suggested that in order to use this feature with shared configuration datastores, configuration locking also be used.

8.5.2. Dependencies

None

8.5.3. Capability Identifier

The :rollback-on-error capability is identified by the following capability string:

```
urn:ietf:params:netconf:capability:rollback-on-error:1.0
```

8.5.4. New Operations

None.

8.5.5. Modifications to Existing Operations

8.5.5.1. <edit-config>

The :rollback-on-error capability allows the "rollback-on-error" value to the <error-option> parameter on the <edit-config> operation.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <error-option>rollback-on-error</error-option>
    <config>
      <top xmlns="http://example.com/schema/1.2/config">
        <interface>
          <name>Ethernet0/0</name>
          <mtu>100000</mtu>
        </interface>
      </top>
    </config>
  </edit-config>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

8.6. Validate Capability

8.6.1. Description

Validation consists of checking a complete configuration for syntactical and semantic errors before applying the configuration to the device.

If this capability is advertised, the device supports the <validate> protocol operation and checks at least for syntax errors. In addition, this capability supports the <test-option> parameter to the <edit-config> operation and, when it is provided, checks at least for syntax errors.

Version 1.0 of this capability was defined in [RFC4741]. Version 1.1 is defined in this document, and extends version 1.0 by adding a new value, "test-only", to the <test-option> parameter of the <edit-config> operation. For backwards compatibility with old clients, servers confirming to this specification MAY advertise version 1.0 in addition to version 1.1.

8.6.2. Dependencies

None.

8.6.3. Capability Identifier

The :validate:1.1 capability is identified by the following capability string:

urn:ietf:params:netconf:capability:validate:1.1

8.6.4. New Operations

8.6.4.1. <validate>

Description:

This protocol operation validates the contents of the specified configuration.

Parameters:

source:

Name of the configuration datastore to validate, such as <candidate>, or the <config> element containing the complete configuration to validate.

Positive Response:

If the device was able to satisfy the request, an `<rpc-reply>` is sent that contains an `<ok>` element.

Negative Response:

An `<rpc-error>` element is included in the `<rpc-reply>` if the request cannot be completed for any reason.

A `<validate>` operation can fail for a number of reasons, such as syntax errors, missing parameters, references to undefined configuration data or any other violations of rules established by the underlying data model.

Example:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <validate>
    <source>
      <candidate/>
    </source>
  </validate>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

8.6.5. Modifications to Existing Operations

8.6.5.1. `<edit-config>`

The `:validate:1.1` capability modifies the `<edit-config>` operation to accept the `<test-option>` parameter.

8.7. Distinct Startup Capability

8.7.1. Description

The device supports separate running and startup configuration datastores. The startup configuration is loaded by the device when it boots. Operations that affect the running configuration will not be automatically copied to the startup configuration. An explicit `<copy-config>` operation from the `<running>` to the `<startup>` is used to update the startup configuration to the current contents of the

running configuration. NETCONF protocol operations refer to the startup datastore using the <startup> element.

8.7.2. Dependencies

None.

8.7.3. Capability Identifier

The :startup capability is identified by the following capability string:

urn:ietf:params:netconf:capability:startup:1.0

8.7.4. New Operations

None.

8.7.5. Modifications to Existing Operations

8.7.5.1. General

The :startup capability adds the <startup/> configuration datastore to arguments of several NETCONF operations. The server MUST support the following additional values:

Operation	Parameters	Notes
<get-config>	<source>	
<copy-config>	<source> <target>	
<lock>	<target>	
<unlock>	<target>	
<validate>	<source>	If :validate:1.1 is advertised
<delete-config>	<target>	Resets the device to its factory defaults

To save the startup configuration, use the <copy-config> operation to copy the <running> configuration datastore to the <startup> configuration datastore.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <copy-config>
    <target>
      <startup/>
    </target>
    <source>
      <running/>
    </source>
  </copy-config>
</rpc>
```

8.8. URL Capability

8.8.1. Description

The NETCONF peer has the ability to accept the <url> element in <source> and <target> parameters. The capability is further identified by URL arguments indicating the URL schemes supported.

8.8.2. Dependencies

None.

8.8.3. Capability Identifier

The :url capability is identified by the following capability string:

```
urn:ietf:params:netconf:capability:url:1.0?scheme={name,...}
```

The :url capability URI MUST contain a "scheme" argument assigned a comma-separated list of scheme names indicating which schemes the NETCONF peer supports. For example:

```
urn:ietf:params:netconf:capability:url:1.0?scheme=http,ftp,file
```

8.8.4. New Operations

None.

8.8.5. Modifications to Existing Operations

8.8.5.1. <edit-config>

The :url capability modifies the <edit-config> operation to accept the <url> element as an alternative to the <config> parameter.

The file that the url refers to contains the configuration data

hierarchy to be modified, encoded in XML under the element <config> in the "urn:ietf:params:xml:ns:netconf:base:1.0" namespace.

8.8.5.2. <copy-config>

The :url capability modifies the <copy-config> operation to accept the <url> element as the value of the <source> and the <target> parameters.

The file that the url refers to contains the complete datastore, encoded in XML under the element <config> in the "urn:ietf:params:xml:ns:netconf:base:1.0" namespace.

8.8.5.3. <delete-config>

The :url capability modifies the <delete-config> operation to accept the <url> element as the value of the <target> parameters.

8.8.5.4. <validate>

The :url capability modifies the <validate> operation to accept the <url> element as the value of the <source> parameter.

8.9. XPath Capability

8.9.1. Description

The XPath capability indicates that the NETCONF peer supports the use of XPath expressions in the <filter> element. XPath is described in [W3C.REC-xpath-19991116].

The data model used in the XPath expression is the same as that used in XPath 1.0 [W3C.REC-xpath-19991116], with the same extension for root node children as used by XSLT 1.0 [W3C.REC-xslt-19991116] (section 3.1). Specifically, it means that the root node MAY have any number of element nodes as its children.

The XPath expression is evaluated in the following context:

- o The set of namespace declarations are those in scope on the <filter> element.
- o The set of variable bindings is defined by the data model. If no such variable bindings are defined, the set is empty.
- o The function library is the core function library, plus any functions defined by the data model.

- o The context node is the root node.

The XPath expression MUST return a node set. If it does not return a node set, the operation fails with an "invalid-value" error.

The response message contains the subtrees selected by the filter expression. For each such subtree, the path from the data model root node down to the subtree, including any elements or attributes necessary to uniquely identify the subtree, are included in the response message. Specific data instances are not duplicated in the response.

8.9.2. Dependencies

None.

8.9.3. Capability Identifier

The :xpath capability is identified by the following capability string:

urn:ietf:params:netconf:capability:xpath:1.0

8.9.4. New Operations

None.

8.9.5. Modifications to Existing Operations

8.9.5.1. <get-config> and <get>

The :xpath capability modifies the <get> and <get-config> operations to accept the value "xpath" in the "type" attribute of the <filter> element. When the "type" attribute is set to "xpath", a "select" attribute MUST be present on the <filter> element. The "select" attribute will be treated as an XPath expression and used to filter the returned data. The <filter> element itself MUST be empty in this case.

The XPath result for the select expression MUST be a node-set. Each node in the node-set MUST correspond to a node in underlying data model. In order to properly identify each node, the following encoding rules are defined:

- o All ancestor nodes of the result node MUST be encoded first, so the <data> element returned in the reply contains only fully-specified sub-trees, according to the underlying data model.

- o If any sibling or ancestor nodes of the result node are needed to identify a particular instance within a conceptual data structure, then these nodes MUST also be encoded in the response.

For example:

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <!-- get the user named fred -->
    <filter xmlns:t="http://example.com/schema/1.2/config"
      type="xpath"
      select="/t:top/t:users/t:user[t:name='fred']"/>
    </get-config>
  </rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <top xmlns="http://example.com/schema/1.2/config">
      <users>
        <user>
          <name>fred</name>
          <company-info>
            <id>2</id>
          </company-info>
        </user>
      </users>
    </top>
  </data>
</rpc-reply>
```

9. Security Considerations

This section provides security considerations for the base NETCONF message layer and the base operations of the NETCONF protocol. Security considerations for the NETCONF transports are provided in the transport documents and security considerations for the content manipulated by NETCONF can be found in the documents defining data models.

This document does not specify an authorization scheme, as such a scheme will likely be tied to a meta-data model or a data model. Implementors SHOULD provide a comprehensive authorization scheme with NETCONF.

Authorization of individual users via the NETCONF server may or may not map 1:1 to other interfaces. First, the data models might be incompatible. Second, it could be desirable to authorize based on mechanisms available in the secure transport layer (SSH, BEEP, etc).

In addition, operations on configurations could have unintended consequences if those operations are also not guarded by the global lock on the files or objects being operated upon. For instance, a partially complete access list could be committed from a candidate configuration unbeknownst to the owner of the lock of the candidate configuration, leading to either an insecure or inaccessible device if the lock on the candidate configuration does not also apply to the <copy-config> operation when applied to it.

Configuration information is by its very nature sensitive. Its transmission in the clear and without integrity checking leaves devices open to classic eavesdropping and false data injection attacks. Configuration information often contains passwords, user names, service descriptions, and topological information, all of which are sensitive. Because of this, this protocol SHOULD be implemented carefully with adequate attention to all manner of attack one might expect to experience with other management interfaces.

The protocol, therefore, MUST minimally support options for both confidentiality and authentication. It is anticipated that the underlying protocol (SSH, BEEP, etc) will provide for both confidentiality and authentication, as is required. It is further expected that the identity of each end of a NETCONF session will be available to the other in order to determine authorization for any given request. One could also easily envision additional information, such as transport and encryption methods, being made available for purposes of authorization. NETCONF itself provide no means to re-authenticate, much less authenticate. All such actions occur at lower layers.

Different environments may well allow different rights prior to and then after authentication. Thus, an authorization model is not specified in this document. When an operation is not properly authorized, a simple "access denied" is sufficient. Note that authorization information can be exchanged in the form of configuration information, which is all the more reason to ensure the security of the connection.

That having been said, it is important to recognize that some operations are clearly more sensitive by nature than others. For instance, <copy-config> to the startup or running configurations is clearly not a normal provisioning operation, whereas <edit-config> is. Such global operations MUST disallow the changing of information that an individual does not have authorization to perform. For example, if a user A is not allowed to configure an IP address on an interface but user B has configured an IP address on an interface in the <candidate> configuration, user A MUST NOT be allowed to commit the <candidate> configuration.

Similarly, just because someone says "go write a configuration through the URL capability at a particular place", this does not mean that an element will do it without proper authorization.

The <lock> operation will demonstrate that NETCONF is intended for use by systems that have at least some trust of the administrator. As specified in this document, it is possible to lock portions of a configuration that a principal might not otherwise have access to. After all, the entire configuration is locked. To mitigate this problem, there are two approaches. It is possible to kill another NETCONF session programmatically from within NETCONF if one knows the session identifier of the offending session. The other possible way to break a lock is to provide an function within the device's native user interface. These two mechanisms suffer from a race condition that could be ameliorated by removing the offending user from an AAA server. However, such a solution is not useful in all deployment scenarios, such as those where SSH public/private key pairs are used.

10. IANA Considerations

10.1. NETCONF XML Namespace

This document registers a URI for the NETCONF XML namespace in the IETF XML registry [RFC3688].

IANA is requested to update the allocation of the following URI to reference this document when it is published as an RFC.

URI: urn:ietf:params:xml:ns:netconf:base:1.0

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

10.2. NETCONF XML Schema

This document registers a URI for the NETCONF XML schema in the IETF XML registry [RFC3688].

IANA is requested to update the allocation of the following URI to reference this document when it is published as an RFC.

URI: urn:ietf:params:xml:schema:netconf

Registrant Contact: The IESG.

XML: Appendix B of this document.

10.3. NETCONF YANG Module

This document registers a YANG module in the YANG Module Names registry [RFC6020].

name:	ietf-netconf
namespace:	urn:ietf:params:xml:ns:netconf:base:1.0
prefix:	nc
reference:	RFCXXXX

10.4. NETCONF Capability URNs

IANA has created and will maintain a registry "Network Configuration Protocol (NETCONF) Capability URNs" that allocates NETCONF capability identifiers. Additions to the registry require IETF Standards Action.

IANA is requested to update the allocations of the following

capabilities to reference this document when it is published as an RFC.

Index	Capability Identifier
:writable-running	urn:ietf:params:netconf:capability:writable-running:1.0
:candidate	urn:ietf:params:netconf:capability:candidate:1.0
:rollback-on-error	urn:ietf:params:netconf:capability:rollback-on-error:1.0
:startup	urn:ietf:params:netconf:capability:startup:1.0
:url	urn:ietf:params:netconf:capability:url:1.0
:xpath	urn:ietf:params:netconf:capability:xpath:1.0

IANA is requested to add the following capabilities to the registry:

Index	Capability Identifier
:base:1.1	urn:ietf:params:netconf:base:1.1
:confirmed-commit:1.1	urn:ietf:params:netconf:capability:confirmed-commit:1.1
:validate:1.1	urn:ietf:params:netconf:capability:validate:1.1

11. Authors and Acknowledgements

This document was written by:

Andy Bierman

Ken Crozier, Cisco Systems

Rob Enns, Juniper Networks

Ted Goddard, IceSoft

Eliot Lear, Cisco Systems

Phil Shafer, Juniper Networks

Steve Waldbusser

Margaret Wasserman, ThingMagic

The authors would like to acknowledge the members of the NETCONF working group. In particular, we would like to thank Wes Hardaker for his persistence and patience in assisting us with security considerations. We would also like to thank Randy Presuhn, Sharon Chisholm, Glenn Waters, David Perkins, Weijing Chen, Simon Leinen, Keith Allen, Dave Harrington, Ladislav Lhotka, Tom Petch, and Kent Watsen for all of their valuable advice.

Appendix A. NETCONF Error List

This section is normative.

For each error-tag, the valid error-type and error-severity values are listed, together with any mandatory error-info, if any.

error-tag:	in-use
error-type:	protocol, application
error-severity:	error
error-info:	none
Description:	The request requires a resource that already is in use.
error-tag:	invalid-value
error-type:	protocol, application
error-severity:	error
error-info:	none
Description:	The request specifies an unacceptable value for one or more parameters.
error-tag:	too-big
error-type:	transport, rpc, protocol, application
error-severity:	error
error-info:	none
Description:	The request or response (that would be generated) is too large for the implementation to handle.
error-tag:	missing-attribute
error-type:	rpc, protocol, application
error-severity:	error
error-info:	<bad-attribute> : name of the missing attribute <bad-element> : name of the element that is supposed to contain the missing attribute
Description:	An expected attribute is missing.
error-tag:	bad-attribute
error-type:	rpc, protocol, application
error-severity:	error
error-info:	<bad-attribute> : name of the attribute w/ bad value <bad-element> : name of the element that contains the attribute with the bad value
Description:	An attribute value is not correct; e.g., wrong type, out of range, pattern mismatch.
error-tag:	unknown-attribute
error-type:	rpc, protocol, application
error-severity:	error

error-info: <bad-attribute> : name of the unexpected attribute
<bad-element> : name of the element that contains
the unexpected attribute
Description: An unexpected attribute is present.

error-tag: missing-element
error-type: protocol, application
error-severity: error
error-info: <bad-element> : name of the missing element
Description: An expected element is missing.

error-tag: bad-element
error-type: protocol, application
error-severity: error
error-info: <bad-element> : name of the element w/ bad value
Description: An element value is not correct; e.g., wrong type,
out of range, pattern mismatch.

error-tag: unknown-element
error-type: protocol, application
error-severity: error
error-info: <bad-element> : name of the unexpected element
Description: An unexpected element is present.

error-tag: unknown-namespace
error-type: protocol, application
error-severity: error
error-info: <bad-element> : name of the element that contains
the unexpected namespace
<bad-namespace> : name of the unexpected namespace
Description: An unexpected namespace is present.

error-tag: access-denied
error-type: protocol, application
error-severity: error
error-info: none
Description: Access to the requested protocol operation, or
data model is denied because authorization failed.

error-tag: lock-denied
error-type: protocol
error-severity: error
error-info: <session-id> : session ID of session holding the
requested lock, or zero to indicate a non-NETCONF
entity holds the lock
Description: Access to the requested lock is denied because the
lock is currently held by another entity.

error-tag: resource-denied
error-type: transport, rpc, protocol, application
error-severity: error
error-info: none
Description: Request could not be completed because of insufficient resources.

error-tag: rollback-failed
error-type: protocol, application
error-severity: error
error-info: none
Description: Request to rollback some configuration change (via rollback-on-error or discard-changes operations) was not completed for some reason.

error-tag: data-exists
error-type: application
error-severity: error
error-info: none
Description: Request could not be completed because the relevant data model content already exists. For example, a "create" operation was attempted on data that already exists.

error-tag: data-missing
error-type: application
error-severity: error
error-info: none
Description: Request could not be completed because the relevant data model content does not exist. For example, a "delete" operation was attempted on data that does not exist.

error-tag: operation-not-supported
error-type: protocol, application
error-severity: error
error-info: none
Description: Request could not be completed because the requested operation is not supported by this implementation.

error-tag: operation-failed
error-type: rpc, protocol, application
error-severity: error
error-info: none
Description: Request could not be completed because the requested operation failed for some reason not covered by any other error condition.

error-tag: partial-operation
error-type: application
error-severity: error
error-info: <ok-element> : identifies an element in the data
model for which the requested operation has been
completed for that node and all its child nodes.
This element can appear zero or more times in the
<error-info> container.

<err-element> : identifies an element in the data
model for which the requested operation has failed
for that node and all its child nodes.
This element can appear zero or more times in the
<error-info> container.

<noop-element> : identifies an element in the data
model for which the requested operation was not
attempted for that node and all its child nodes.
This element can appear zero or more times in the
<error-info> container.

Description: This error-tag is obsolete, and SHOULD NOT be sent
by servers conforming to this document.

Some part of the requested operation failed or was
not attempted for some reason. Full cleanup has
not been performed (e.g., rollback not supported)
by the server. The error-info container is used
to identify which portions of the application
data model content for which the requested operation
has succeeded (<ok-element>), failed (<bad-element>),
or not been attempted (<noop-element>).

error-tag: malformed-message
error-type: rpc
error-severity: error
error-info: none

Description: A message could not be handled because it failed to
be parsed correctly. For example, the message is not
well-formed XML or it uses an invalid character set.

This error-tag is new in :base:1.1 and MUST NOT be
sent to old clients.

Appendix B. XML Schema for NETCONF Messages Layer

This section is normative.

<CODE BEGINS> file "netconf.xsd"

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"

extension get-filter-element-attributes {
  description
    "If this extension is present within the
    an 'anyxml' statement named 'filter', which must be
    conceptually defined within the RPC input section
    for the 'get' and 'get-config' protocol operations,
    then the following unqualified XML attribute is
    supported within the 'filter' element, within
    a 'get' or 'get-config' protocol operation:

    type : optional attribute with allowed
           value strings 'subtree' and 'xpath'.
           If missing, the default value is 'subtree'.

    If the 'xpath' feature is supported, then the
    following unqualified XML attribute is
    also supported:

    select: optional attribute containing a
            string representing an XPath expression.
            The 'type' attribute must be equal to 'xpath'
            if this attribute is present.";

<CODE ENDS>

Appendix D. Capability Template

This non-normative section defines a template that can be used to define protocol capabilities. Data models written in YANG usually do not need to define protocol capabilities since the usage of YANG automatically leads to a capability announcing the data model and any optional portions of the data model, so called features in YANG terminology. The capabilities template is intended to be used in cases where the YANG mechanisms are not powerful enough (e.g., for handling parametrized features) or a different data modeling language is used.

D.1. capability-name (template)

D.1.1. Overview

D.1.2. Dependencies

D.1.3. Capability Identifier

The {name} capability is identified by the following capability string:

```
{capability uri}
```

D.1.4. New Operations

D.1.4.1. <op-name>

D.1.5. Modifications to Existing Operations

D.1.5.1. <op-name>

If existing operations are not modified by this capability, this section may be omitted.

D.1.6. Interactions with Other Capabilities

If this capability does not interact with other capabilities, this section may be omitted.

Appendix E. Configuring Multiple Devices with NETCONF

This section is non-normative.

E.1. Operations on Individual Devices

Consider the work involved in performing a configuration update against a single individual device. In making a change to the configuration, the application needs to build trust that its change has been made correctly and that it has not impacted the operation of the device. The application (and the application user) should feel confident that their change has not damaged the network.

Protecting each individual device consists of a number of steps:

- o Acquiring the configuration lock.
- o Checkpointing the running configuration.
- o Loading and validating the incoming configuration.
- o Changing the running configuration.
- o Testing the new configuration.
- o Making the change permanent (if desired).
- o Releasing the configuration lock.

Let's look at the details of each step.

E.1.1. Acquiring the Configuration Lock

A lock should be acquired to prevent simultaneous updates from multiple sources. If multiple sources are affecting the device, the application is hampered in both testing of its change to the configuration and in recovery if the update fails. Acquiring a short-lived lock is a simple defense to prevent other parties from introducing unrelated changes.

The lock can be acquired using the <lock> operation.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <lock>
    <target>
      <running/>
    </target>
  </lock>
</rpc>
```

If the :candidate capability is supported, the candidate configuration should be locked.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <lock>
    <target>
      <candidate/>
    </target>
  </lock>
</rpc>
```

E.1.1.2. Checkpointing the Running Configuration

The running configuration can be saved into a local file as a checkpoint before loading the new configuration. If the update fails, the configuration can be restored by reloading the checkpoint file.

The checkpoint file can be created using the <copy-config> operation.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <copy-config>
    <target>
      <url>file://checkpoint.conf</url>
    </target>
    <source>
      <running/>
    </source>
  </copy-config>
</rpc>
```

To restore the checkpoint file, reverse the <source> and <target> parameters.

E.1.3. Loading and Validating the Incoming Configuration.

If the `:candidate` capability is supported, the configuration can be loaded onto the device without impacting the running system.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <candidate/>
    </target>
    <config>
      <!-- place incoming configuration changes here -->
    </config>
  </edit-config>
</rpc>
```

If the device supports the `:validate:1.1` capability, it will by default validate the incoming configuration when it is loaded into the candidate. To avoid this validation, pass the `<test-option>` parameter with the value "set". Full validation can be requested with the `<validate>` operation.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <validate>
    <source>
      <candidate/>
    </source>
  </validate>
</rpc>
```

E.1.4. Changing the Running Configuration

When the incoming configuration has been safely loaded onto the device and validated, it is ready to impact the running system.

If the device supports the `:candidate` capability, use the `<commit>` operation to set the running configuration to the candidate configuration. Use the `<confirmed>` parameter to allow automatic reversion to the original configuration if connectivity to the device fails.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <commit>
    <confirmed/>
    <confirm-timeout>120</confirm-timeout>
  </commit>
</rpc>
```

If the candidate is not supported by the device, the incoming configuration change is loaded directly into running.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config>
      <!-- place incoming configuration changes here -->
    </config>
  </edit-config>
</rpc>
```

E.1.1.5. Testing the New Configuration

Now that the incoming configuration has been integrated into the running configuration, the application needs to gain trust that the change has affected the device in the way intended without affecting it negatively.

To gain this confidence, the application can run tests of the operational state of the device. The nature of the test is dependent on the nature of the change and is outside the scope of this document. Such tests may include reachability from the system running the application (using ping), changes in reachability to the rest of the network (by comparing the device's routing table), or inspection of the particular change (looking for operational evidence of the BGP peer that was just added).

E.1.1.6. Making the Change Permanent

When the configuration change is in place and the application has sufficient faith in the proper function of this change, the application is expected to make the change permanent.

If the device supports the :startup capability, the current configuration can be saved to the startup configuration by using the startup configuration as the target of the <copy-config> operation.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <copy-config>
    <target>
      <startup/>
    </target>
    <source>
      <running/>
    </source>
  </copy-config>
</rpc>
```

If the device supports the :candidate capability and a confirmed commit was requested, the confirming commit must be sent before the timeout expires.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <commit/>
</rpc>
```

E.1.7. Releasing the Configuration Lock

When the configuration update is complete, the lock must be released, allowing other applications access to the configuration.

Use the <unlock> operation to release the configuration lock.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <unlock>
    <target>
      <running/>
    </target>
  </unlock>
</rpc>
```

If the :candidate capability is supported, the candidate configuration should be unlocked.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <unlock>
    <target>
      <candidate/>
    </target>
  </unlock>
</rpc>
```

E.2. Operations on Multiple Devices

When a configuration change requires updates across a number of devices, care needs to be taken to provide the required transaction semantics. The NETCONF protocol contains sufficient primitives upon which transaction-oriented operations can be built. Providing complete transactional semantics across multiple devices is prohibitively expensive, but the size and number of windows for failure scenarios can be reduced.

There are two classes of multi-device operations. The first class allows the operation to fail on individual devices without requiring all devices to revert to their original state. The operation can be retried at a later time, or its failure simply reported to the user. An example of this class might be adding an NTP server. For this class of operations, failure avoidance and recovery are focused on the individual device. This means recovery of the device, reporting the failure, and perhaps scheduling another attempt.

The second class is more interesting, requiring that the operation should complete on all devices or be fully reversed. The network should either be transformed into a new state or be reset to its original state. For example, a change to a VPN may require updates to a number of devices. Another example of this might be adding a class-of-service definition. Leaving the network in a state where only a portion of the devices have been updated with the new definition will lead to future failures when the definition is referenced.

To give transactional semantics, the same steps used in single device operations listed above are used, but are performed in parallel across all devices. Configuration locks should be acquired on all target devices and kept until all devices are updated and the changes made permanent. Configuration changes should be uploaded and validation performed across all devices. Checkpoints should be made on each device. Then the running configuration can be changed, tested, and made permanent. If any of these steps fail, the previous configurations can be restored on any devices upon which they were changed. After the changes have been completely implemented or completely discarded, the locks on each device can be released.

Appendix F. Changes from RFC 4741

This section lists major changes between this document and RFC 4741.

- o Added the "malformed-message" error-tag.
- o Added "remove" enumeration value to the "operation" attribute.
- o Obsoleted the "partial-operation" error-tag enumeration value.
- o Added <persist> and <persist-id> parameters to the <commit> operation.
- o Updated the base protocol URI and clarified the <hello> message exchange to select and identify the base protocol version in use for a particular session.
- o Added a YANG module to model the operations and removed the operation layer from the XSD.
- o Clarified lock behavior for the candidate datastore.
- o Clarified the error response server requirements for the "delete" enumeration value of the "operation" attribute.
- o Added a namespace wildcarding mechanism for subtree filtering.
- o Added a "test-only" value for the <test-option> parameter to the <edit-config> operation.
- o Added a <cancel-commit> operation.
- o Introduced a NETCONF username and a requirement for transport protocols to explain how a username is derived.

With-defaults capability for NETCONF
draft-ietf-netconf-with-defaults-14

Abstract

The NETCONF protocol defines ways to read and edit configuration data from a NETCONF server. In some cases, part of this data may not be set by the NETCONF client, but rather a default value known to the server is used instead. In many situations the NETCONF client has a priori knowledge about default data, so the NETCONF server does not need to save it in a NETCONF configuration datastore or send it to the client in a retrieval operation reply. In other situations the NETCONF client will need this data from the server. Not all server implementations treat this default data the same way. This document defines a capability-based extension to the NETCONF protocol that allows the NETCONF client to identify how defaults are processed by the server, and also defines new mechanisms for client control of server processing of default data.

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 15, 2011.

1. Introduction

The NETCONF protocol [I-D.ietf-netconf-4741bis] defines ways to read configuration and state data from a NETCONF server. Part of the configuration data may not be set by the NETCONF client, but rather by a default value from the data model. In many situations the NETCONF client has a priori knowledge about default data, so the NETCONF server does not need to send it to the client. A priori knowledge can be obtained, e.g., a document formally describing the data models supported by the NETCONF server.

It can be important for a client to know exactly how a server implementation will handle default data. There are subtle differences in some protocol operations where the defaults handling behavior of the server will affect the outcome of the operation.

1.1. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

Data model schema: A document or set of documents describing the data models supported by the NETCONF server.

Management Application: A computer program running outside the NETCONF server that configures or supervises the NETCONF server. A management application can reach the device e.g. via NETCONF, command line interface (CLI) or Simple Network Management Protocol (SNMP).

Schema default data: Data specified in the data model schema as default, that is set or used by the device whenever the NETCONF client or other management application/user does not provide a specific value for the relevant data node. Schema default data may or may not be stored as part of a configuration datastore, depending on the basic mode used by a particular server.

Default data: Conceptual data containing a default value. Default data is not kept in a datastore. Not all servers use the same criteria to decide if a data node is actually instantiated in a datastore. If a data node is not present in a datastore, and a schema default definition is in use by the server instead, then it is considered to be a default data node.

Default value: A default value is a value for a data node instance that is conceptually in use by the server, when the data node instance does not exist.

Explicitly set data: Data that is set to any value by a NETCONF client or other management application by the way of an explicit management operation, including any data model schema default value. Any value set by the NETCONF server which is not the schema defined default value is also considered explicitly set data.

<with-defaults> retrieval: Refers to a protocol operation which includes the <with-default> parameter to control the handling of default data.

:with-defaults: The shorthand notation for the with-defaults capability identifier.

The following terms are defined in [I-D.ietf-netconf-4741bis]:

- o client
- o datastore
- o operation
- o server

The following term is defined in [RFC6020]:

- o data node

1.2. Defaults Handling Behavior

The defaults handling behavior used by a server will impact NETCONF protocol operations in two ways:

1. Data retrieval: A server is normally allowed to exclude data nodes which it considers to contain the default value. The actual nodes omitted depends on the defaults handling behavior used by the server.
2. Create and delete operations: The <edit-config> 'operation' attribute can be used to create and/or delete specific data nodes. These operations depend on whether the target node currently exists or not. The server's defaults handling behavior will determine whether the requested node currently exists in the configuration datastore or not.

1.3. Client Controlled Retrieval of Default Data

A networking device may have a large number of default values. Often the default values are specifically defined with a reasonable value, documented and well-known, so that the management user does not need to handle them. For these reasons it is quite common for networking devices to suppress the output of parameters having the default value.

However, there are use-cases when a NETCONF client will need the default data from the server:

- o The management application often needs a single, definitive and complete set of configuration values that determine how the networking device works.
- o Documentation about default values can be unreliable or unavailable.
- o Some management applications might not have the capabilities to correctly parse and interpret formal data models.
- o Human users might want to understand the received data without consultation of the documentation.

In all these cases, the NETCONF client will need a mechanism to retrieve default data from a NETCONF server.

This document defines a NETCONF protocol capability to identify the server defaults handling behavior, an XML attribute to identify default data, and a YANG module extension to the NETCONF protocol that allows the NETCONF client to control whether default data is returned by the server.

2. Defaults Handling Basic Modes

Not all server implementations treat default data in the same way. Instead of forcing a single implementation strategy, this document allows a server to advertise a particular style of defaults handling, and the client can adjust accordingly.

NETCONF servers report default data in different ways. This document specifies three standard defaults handling basic modes that a server implementor may choose from:

- o report-all
- o trim
- o explicit

A server MUST select one of the three basic modes defined in this section for handling default data.

2.1. 'report-all' Basic Mode

A server which uses the 'report-all' basic mode does not consider any data node to be default data, even schema default data.

2.1.1. 'report-all' Basic Mode Retrieval

When data is retrieved from a server using the 'report-all' basic mode, and the <with-defaults> parameter is not present, all data nodes MUST be reported.

2.1.2. 'report-all' <with-defaults> Retrieval

If the 'report-all' basic mode is used by the server, then the server MUST support the <with-defaults> parameter with a value equal to 'report-all', as specified in Section 3.1.

2.1.3. 'report-all' <edit-config> and <copy-config> Behavior

The server MUST consider every data node to exist, even those containing a schema default value. A valid 'create' operation attribute for a data node that contains its schema default value MUST fail with a 'data-exists' error-tag. A valid 'delete' operation attribute for a data node that contains its schema default value MUST succeed, even though the data node is immediately replaced by the server with the default value.

A server which uses the 'report-all' basic-mode has no concept of a default node, so the 'report-all-tagged' <with-defaults> retrieval mode is not relevant. There will never be any tagged nodes, since there are no nodes which are omitted in a basic-mode retrieval operation. If the 'default' attribute is present in any configuration data, the server MUST return an <rpc-error> response with an 'unknown-attribute' error-tag.

2.2. 'trim' Basic Mode

A server which uses the 'trim' basic mode MUST consider any data node set to its schema default value to be default data.

2.2.1. 'trim' Basic Mode Retrieval

When data is retrieved from a server using the 'trim' basic mode, and the <with-defaults> parameter is not present, data nodes MUST NOT be reported if they contain the schema default value. Non-configuration data nodes containing the schema default value MUST NOT be reported.

2.2.2. 'trim' <with-defaults> Retrieval

If the 'trim' basic mode is used by the server, then the server MUST support the <with-defaults> parameter with a value equal to 'trim', as specified in Section 3.2.

2.2.3. 'trim' <edit-config> and <copy-config> Behavior

The server MUST consider any data node that does not contain its schema default value to exist. A valid 'create' operation attribute for a data node that has a schema default value defined MUST succeed. A valid 'delete' operation attribute for a missing data node that has a schema default value MUST fail. The server MUST return an <rpc-error> response with a 'data-missing' error-tag.

If a client sets a data node to its schema default value, using any valid operation, it MUST succeed, although the data node MUST NOT be saved in the NETCONF configuration datastore. This has the same effect as removing the data node and treating it as default data.

If the server supports the 'report-all-tagged' value for the <with-defaults> parameter, then the 'default' attribute MUST be accepted in configuration input, as described in Section 4.5.1 and Section 4.5.2.

2.3. 'explicit' Basic Mode

A server which uses the 'explicit' basic mode MUST consider any data node that is not explicitly set data to be default data.

2.3.1. 'explicit' Basic Mode Retrieval

When data is retrieved from a server using the 'explicit' basic mode, and the <with-defaults> parameter is not present, data nodes MUST be reported if explicitly set by the client, even if they contain the schema default value. Non-configuration data nodes containing the schema default value MUST be reported.

2.3.2. 'explicit' <with-defaults> Retrieval

If the 'explicit' basic mode is used by the server, the server MUST support the <with-defaults> parameter with a value equal to 'explicit', as specified in Section 3.3.

2.3.3. 'explicit' <edit-config> and <copy-config> Behavior

The server considers any data node that is explicitly set data to exist. A valid 'create' operation attribute for a data node that has been set by a client to its schema default value MUST fail with a 'data-exists' error-tag. A valid 'create' operation attribute for a data node that has been set by the server to its schema default value MUST succeed. A valid 'delete' operation attribute for a data node that has been set by a client to its schema default value MUST succeed. A valid 'delete' operation attribute for a data node that has been set by the server to its schema default value MUST fail with

a 'data-missing' error-tag.

If the server supports the 'report-all-tagged' retrieval mode in its :with-defaults capability, then the 'default' attribute MUST be accepted in configuration input. If all NETCONF <edit-config> or <copy-config> parameters are valid, then the server will treat a tagged data node (i.e., the 'default' attribute set to 'true' or '1') as a request to return that node to default data. If this request is valid within the context of the requested NETCONF operation, then the data node is removed and returned to its default value. The data node within the NETCONF message MUST contain a value in this case, which MUST be equal to the schema default value. If not, the server MUST return an <rpc-error> response with a 'invalid-value' error-tag.

3. Retrieval of Default Data

This document defines a new parameter, called <with-defaults>, which can be added to specific NETCONF operation request messages to control how retrieval of default data is treated by the server.

A server which implements this specification MUST accept the <with-defaults> parameter containing the enumeration for any of the defaults handling modes it supports. The <with-defaults> parameter contains one of the four enumerations defined in this section.

3.1. 'report-all' Retrieval Mode

When data is retrieved with a <with-defaults> parameter equal to 'report-all', all data nodes MUST be reported, including any data nodes considered to be default data by the server.

3.2. 'trim' Retrieval Mode

When data is retrieved with a <with-defaults> parameter equal to 'trim', data nodes MUST NOT be reported if they contain the schema default value. Non-configuration data nodes containing the schema default value MUST NOT be reported.

3.3. 'explicit' Retrieval Mode

When data is retrieved with a <with-defaults> parameter equal to 'explicit', a data node which was set by a client to its schema default value MUST be reported. A conceptual data node which would be set by the server to the schema default value MUST NOT be reported. Non-configuration data nodes containing the schema default value MUST be reported.

3.4. 'report-all-tagged' Retrieval Mode

In addition to the basic modes, a special variant of the 'report-all' basic mode is available called 'report-all-tagged'. This mode MUST be supported on a server if the 'also-supported' parameter in the :with-defaults capability contains the 'report-all-tagged' option. Refer to Section 4 for encoding details for this capability.

In this mode the server returns all data nodes, just like the 'report-all' mode, except a data node that is considered by the server to contain default data will include an XML attribute to indicate this condition. This is useful for an application to determine which nodes are considered to contain default data by the server, within a single retrieval operation.

A server which supports 'report-all-tagged' MUST also accept the 'default' XML attribute within configuration input to the <edit-config> or <copy-config> operations. Refer to Section 6 for XML encoding details of the 'default' XML attribute.

4. With-defaults Capability

4.1. Overview

The :with-defaults capability indicates which defaults handling basic mode is supported by the server. It may also indicate support for additional defaults retrieval modes. These retrieval modes allow a NETCONF client to control whether default data is returned by the server. The capability affects both configuration and state data (while acknowledging that the usage of default values for state data is less prevalent). Sending of default data is controlled for each individual operation separately.

A NETCONF server implementing the :with-defaults capability:

- o MUST indicate its basic mode behavior by including the 'basic-mode' parameter in the capability URI, as defined in Section 4.3.
- o MUST support the YANG module defined in Section 5 for the defaults handling mode indicated by the 'basic-mode' parameter.
- o SHOULD support the YANG module in Section 5 for the defaults handling mode identified by the 'report-all' or 'report-all-tagged' enumeration value.
- o If the 'report-all-tagged' defaults handling mode is supported, then the 'default' attribute MUST be supported.
- o MAY support the YANG module in Section 5 for additional defaults handling modes.

4.2. Dependencies

None

4.3. Capability Identifier

urn:ietf:params:netconf:capability:with-defaults:1.0

The identifier **MUST** have a parameter: "basic-mode". This indicates how the server will treat default data, as defined in Section 2. The allowed values of this parameter are 'report-all', 'trim', and 'explicit', as defined in Section 2.

The identifier **MAY** have another parameter: "also-supported". This parameter indicates which additional enumeration values (besides the basic-mode enumeration), the server will accept for the <with-defaults> parameter in Section 5. The value of the parameter is a comma separated list of one or more modes that are supported beside the mode indicated in the 'basic-mode' parameter. Possible modes are 'report-all', 'report-all-tagged', 'trim', and 'explicit', as defined in Section 3.

Note that this protocol capability URI is separate from the YANG module capability URI for the YANG module in Section 5. A server which implements this module **MUST** also advertise a YANG module capability URI according to the rules specified in [RFC6020].

Examples:

urn:ietf:params:netconf:capability:with-defaults:1.0?basic-mode=explicit

urn:ietf:params:netconf:capability:with-defaults:1.0?basic-mode=explicit&also-supported=report-all,report-all-tagged

4.4. New Operations

None

4.5. Modifications to Existing Operations

4.5.1. <get>, <get-config>, and <copy-config> Operations

A new <with-defaults> XML element is added to the input for the <get>, <get-config> and <copy-config> operations. If the <with-defaults> element is present, it controls the reporting of default data. The server **MUST** return default data in the NETCONF <rpc-reply> messages according to the value of this element, if the server

supports the specified retrieval mode.

This parameter only controls these specified retrieval operations, and does not impact any other operations or the non-volatile storage of configuration data.

The `<with-defaults>` element is defined in the XML namespace for the `ietf-netconf-with-defaults.yang` module in Section 5, not the XML namespace for the `<get>`, `<get-config>` and `<copy-config>` operations.

Allowed values of the `with-defaults` element are taken from the `'with-defaults-type'` typedef in Section 5. The allowed values for a particular server are restricted to the values that the server indicates it supports within the `:with-defaults` capability, in the `'basic-mode'` and `'also-supported'` parameters.

If an unsupported value is used, the NETCONF server MUST return an `<rpc-error>` response with an `'invalid-value'` error-tag.

If the `<with-defaults>` element is not present, the server MUST follow its basic mode behavior as indicated by the `:with-defaults` capability identifier's `'basic-mode'` parameter, defined in Section 4.3.

The `<get>` and `<get-config>` operations support a separate filtering mechanism, using the `<filter>` parameter. The defaults filtering is conceptually done before the `<filter>` parameter is processed. For example, if the `<with-defaults>` parameter is equal to `'report-all'`, then the `<filter>` parameter is conceptually applied to all data nodes and all default data.

The `<copy-config>` operation is only affected by the `<with-defaults>` parameter if the target of the operation is specified with the `<url>` parameter. If the target is a NETCONF configuration datastore (i.e., running, candidate or startup), the `<with-defaults>` parameter has no effect. The server MUST use its basic mode when copying data to a NETCONF configuration datastore. If the `<with-defaults>` parameter is present in this case, it MUST be silently ignored by the server.

If the server supports the `'report-all-tagged'` mode, then the `'default'` attribute defined in Section 6 also impacts the `<copy-config>` operation. If the `'default'` attribute is present and set to `'true'` or `'1'`, then the server MUST treat the new data node as a request to return that node to its default value (i.e., remove it from the configuration datastore). The data node within the NETCONF message MUST contain a value in this case, which MUST be equal to the schema default value. If not, the server MUST return an `<rpc-error>` response with a `'invalid-value'` error-tag.

4.5.2. <edit-config> Operation

The <edit-config> operation has several editing modes. The 'create' and 'delete' editing operations are affected by the defaults handling basic mode. The other enumeration values for the NETCONF operation attribute are not affected.

If the operation attribute contains the value 'create', and the data node already exists in the target configuration datastore, then the server MUST return an <rpc-error> response with a 'invalid-value' error-tag.

If the client sets a data node to its schema default value, the server MUST accept the request if it is valid. The server MUST keep or discard the new value based on its defaults handling basic mode. For the 'trim' basic mode, all schema default values are discarded, otherwise a client-provided schema default value is saved in a NETCONF configuration datastore.

If the server supports the 'report-all-tagged' mode, then the 'default' attribute defined in Section 6 also impacts the <edit-config> operation. If the 'default' attribute is present and set to 'true' or '1', then the server MUST treat the new data node as a request to return that node to its default value (i.e., remove it from the configuration datastore). The data node within the NETCONF message MUST contain a value in this case, which MUST be equal to the schema default value. If not, the server MUST return an <rpc-error> response with a 'invalid-value' error-tag.

If the 'default' attribute is present, then the effective operation for the target data node MUST be 'create', 'merge' or 'replace'. If not, then the server MUST return an <rpc-error> response with an 'invalid-value' error-tag. For example, if 'create' is the effective operation, then the create request must be valid on its own (e.g., current data node MUST NOT exist). The procedure for determining the effective operation is defined in [I-D.ietf-netconf-4741bis]. It is derived from the 'default-operation' parameter and/or any operation attributes that are present in the data node or any of its ancestor nodes, within the <edit-config> request.

4.5.3. Other Operations

Other operations that return configuration data SHOULD also handle default data according to the rules set in this document, and explicitly state this in their documentation. If this is not specified in the document defining the respective operation, the default handling rules described herein do not affect these operations.

4.6. Interactions with Other Capabilities

None

5. YANG Module for the <with-defaults> Parameter

The following YANG module defines the addition of the with-defaults element to the <get>, <get-config>, and <copy-config> operations. The YANG language is defined in [RFC6020]. The above operations are defined in YANG in [I-D.ietf-netconf-4741bis]. Every NETCONF server which supports the :with-defaults capability MUST implement this YANG module.

```
<CODE BEGINS> file="ietf-netconf-with-defaults@2010-11-11.yang"

module ietf-netconf-with-defaults {

    namespace "urn:ietf:params:xml:ns:yang:ietf-netconf-with-defaults";

    prefix ncwd;

    import ietf-netconf { prefix nc; }

}
}

<CODE ENDS>
```

6. XSD for the 'default' Attribute

The following XML Schema document [W3C.REC-xml-20081126] defines the 'default' attribute, described within this document. This XSD is

only relevant if the server supports the 'report-all-tagged' defaults retrieval mode.

The 'default' attribute uses the XSD data type 'boolean'. In accordance with Section 3.2.2.1 of XML Schema Part 2: Datatypes, the allowable lexical representations for the xs:boolean datatype are the strings "0" and "false" for the concept of false and the strings "1" and "true" for the concept of true. Implementations MUST support both styles of lexical representation.

<CODE BEGINS> file="defaults.xsd"

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"
            xmlns="urn:ietf:params:xml:ns:netconf:default:1.0"
            targetNamespace="urn:ietf:params:xml:ns:netconf:default:1.0"
            elementFormDefault="qualified"
            attributeFormDefault="unqualified"
            xml:lang="en">

  <xs:annotation>
    <xs:documentation>
      This schema defines the syntax for the 'default' attribute
      described within this document.
    </xs:documentation>
  </xs:annotation>

  <!--
    default attribute
  -->
  <xs:attribute name="default" type="xs:boolean" default="false">
    <xs:annotation>
      <xs:documentation>
        This attribute indicates whether the data node represented
        by the XML element containing this attribute is considered
        by the server to be default data. If set to 'true' or '1' then
        the data node is default data. If 'false' or '0', then the
        data node is not default data.
      </xs:documentation>
    </xs:annotation>
  </xs:attribute>

</xs:schema>

<CODE ENDS>
```

7. IANA Considerations

This document registers the following capability identifier URN in the 'Network Configuration Protocol Capability URNs registry':

```
urn:ietf:params:netconf:capability:with-defaults:1.0
```

Note that the capability URN is compliant to [I-D.ietf-netconf-4741bis] section 10.3.

This document registers two XML namespace URNs in the 'IETF XML registry', following the format defined in [RFC3688].

```
URI: urn:ietf:params:xml:ns:netconf:default:1.0
```

```
URI: urn:ietf:params:xml:ns:yang:ietf-netconf-with-defaults
```

Registrant Contact: The NETCONF WG of the IETF.

XML: N/A, the requested URIs are XML namespaces.

This document registers one module name in the 'YANG Module Names' registry, defined in [RFC6020] .

```
name: ietf-netconf-with-defaults
```

```
prefix: ncwd
```

```
namespace: urn:ietf:params:xml:ns:yang:ietf-netconf-with-defaults
```

```
RFC: XXXX // RFC Ed.: replace XXXX and remove this comment
```

8. Security Considerations

This document defines an extension to existing NETCONF protocol operations. It does not introduce any new or increased security risks into the management system.

The 'with-defaults' capability gives clients control over the retrieval of default data from a NETCONF datastore. The security consideration of [I-D.ietf-netconf-4741bis] apply to this document as well.

9. Acknowledgements

Thanks to Martin Bjorklund, Sharon Chisholm, Phil Shafer, Juergen Schoenwaelder, Kent Watsen, Washam Fan and many other members of the NETCONF WG for providing important input to this document.

Appendix A. Usage Examples

A.1. Example YANG Module

The following YANG module defines an example interfaces table to demonstrate how the <with-defaults> parameter behaves for a specific data model.

Note that this is not a real module, and implementation of this module is not required for conformance to the :with-defaults capability, defined in Section 4. This module is not to be registered with IANA, and is not considered to be a code component. It is intentionally very terse, and includes few descriptive statements.

```
module example {  
  namespace "http://example.com/ns/interfaces";  
  prefix exam;  
  
  typedef status-type {  
    description "Interface status";  
    type enumeration {  
      enum ok;  
      enum 'waking up';  
      enum 'not feeling so good';  
      enum 'better check it out';  
      enum 'better call for help';  
    }  
    default ok;  
  }  
  
  container interfaces {  
    description "Example interfaces group";  
  
    list interface {  
      description "Example interface entry";  
      key name;  
  
      leaf name {  
        description  
          "The administrative name of the interface.  
          This is an identifier which is only unique  
          within the scope of this list, and only  
          within a specific server.";  
        type string {  
          length "1 .. max";  
        }  
      }  
  
      leaf mtu {  
        description  
          "The maximum transmission unit (MTU) value assigned to  
          this interface.";  
        type uint32;  
        default 1500;  
      }  
  
      leaf status {  
        description  
          "The current status of this interface.";  
        type status-type;  
      }  
    }  
  }  
}
```

```
        config false;
    }
}
}
```

A.2. Example Data Set

The following data element shows the conceptual contents of the example server for the protocol operation examples in the next section. This includes all the configuration data nodes, non-configuration data nodes, and default leafs.

```
<data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <interfaces xmlns="http://example.com/ns/interfaces">
    <interface>
      <name>eth0</name>
      <mtu>8192</mtu>
      <status>up</status>
    </interface>
    <interface>
      <name>eth1</name>
      <mtu>1500</mtu>
      <status>up</status>
    </interface>
    <interface>
      <name>eth2</name>
      <mtu>9000</mtu>
      <status>not feeling so good</status>
    </interface>
    <interface>
      <name>eth3</name>
      <mtu>1500</mtu>
      <status>waking up</status>
    </interface>
  </interfaces>
</data>
```

In this example, the 'mtu' field for each interface entry is set in the following manner:

name	set by	mtu
eth0	client	8192
eth1	server	1500
eth2	client	9000
eth3	client	1500

A.3. Protocol Operation Examples

The following examples shows some <get> operations using the 'with-defaults' element. The data model used for these examples is defined in Appendix A.1.

The client is retrieving all the data nodes within the 'interfaces' object, filtered with the <with-defaults> parameter.

A.3.1. <with-defaults> = 'report-all'

The behavior of the <with-defaults> parameter handling for the value 'report-all' is demonstrated in this example.

```
<rpc message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <interfaces xmlns="http://example.com/ns/interfaces"/>
    </filter>
    <with-defaults
      xmlns="urn:ietf:params:xml:ns:yang:ietf-netconf-with-defaults">
      report-all
    </with-defaults>
  </get>
</rpc>

<rpc-reply message-id="101"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <interfaces xmlns="http://example.com/ns/interfaces">
      <interface>
        <name>eth0</name>
        <mtu>8192</mtu>
        <status>up</status>
      </interface>
      <interface>
        <name>eth1</name>
        <mtu>1500</mtu>
        <status>up</status>
      </interface>
      <interface>
        <name>eth2</name>
        <mtu>9000</mtu>
        <status>not feeling so good</status>
      </interface>
      <interface>
        <name>eth3</name>
        <mtu>1500</mtu>
        <status>waking up</status>
      </interface>
    </interfaces>
  </data>
</rpc-reply>
```

A.3.2. <with-defaults> = 'report-all-tagged'

The behavior of the <with-defaults> parameter handling for the value 'report-all-tagged' is demonstrated in this example. A 'tagged' data node is an element that contains the 'default' XML attribute, set to

'true' or '1'.

The actual data nodes tagged by the server depends on the defaults handling basic mode used by the server. Only the data nodes that are considered to be default data will be tagged.

In this example, the server's basic mode is equal to 'trim', so all data nodes that would contain the schema default value are tagged. If the server's basic mode is 'explicit', then only data nodes that are not explicitly set data are tagged. If the server's basic mode is 'report-all', then no data nodes are tagged.

```
<rpc message-id="102"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <interfaces xmlns="http://example.com/ns/interfaces"/>
    </filter>
    <with-defaults
      xmlns="urn:ietf:params:xml:ns:yang:ietf-netconf-with-defaults">
      report-all-tagged
    </with-defaults>
  </get>
</rpc>

<rpc-reply message-id="102"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
  xmlns:wd="urn:ietf:params:xml:ns:netconf:default:1.0">
  <data>
    <interfaces xmlns="http://example.com/ns/interfaces">
      <interface>
        <name>eth0</name>
        <mtu>8192</mtu>
        <status wd:default="true">up</status>
      </interface>
      <interface>
        <name>eth1</name>
        <mtu wd:default="true">1500</mtu>
        <status wd:default="true">up</status>
      </interface>
      <interface>
        <name>eth2</name>
        <mtu>9000</mtu>
        <status>not feeling so good</status>
      </interface>
      <interface>
        <name>eth3</name>
        <mtu wd:default="true">1500</mtu>
        <status>waking up</status>
      </interface>
    </interfaces>
  </data>
</rpc-reply>
```

A.3.3. <with-defaults> = 'trim'

The behavior of the <with-defaults> parameter handling for the value 'trim' is demonstrated in this example.

```
<rpc message-id="103"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <interfaces xmlns="http://example.com/ns/interfaces"/>
    </filter>
    <with-defaults
      xmlns="urn:ietf:params:xml:ns:yang:ietf-netconf-with-defaults">
      trim
    </with-defaults>
  </get>
</rpc>

<rpc-reply message-id="103"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <interfaces xmlns="http://example.com/ns/interfaces">
      <interface>
        <name>eth0</name>
        <mtu>8192</mtu>
      </interface>
      <interface>
        <name>eth1</name>
      </interface>
      <interface>
        <name>eth2</name>
        <mtu>9000</mtu>
        <status>not feeling so good</status>
      </interface>
      <interface>
        <name>eth3</name>
        <status>waking up</status>
      </interface>
    </interfaces>
  </data>
</rpc-reply>
```

A.3.4. <with-defaults> = 'explicit'

The behavior of the <with-defaults> parameter handling for the value 'explicit' is demonstrated in this example.

```
<rpc message-id="104"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <interfaces xmlns="http://example.com/ns/interfaces"/>
    </filter>
    <with-defaults
      xmlns="urn:ietf:params:xml:ns:yang:ietf-netconf-with-defaults">
      explicit
    </with-defaults>
  </get>
</rpc>

<rpc-reply message-id="104"
  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <interfaces xmlns="http://example.com/ns/interfaces">
      <interface>
        <name>eth0</name>
        <mtu>8192</mtu>
        <status>up</status>
      </interface>
      <interface>
        <name>eth1</name>
        <status>up</status>
      </interface>
      <interface>
        <name>eth2</name>
        <mtu>9000</mtu>
        <status>not feeling so good</status>
      </interface>
      <interface>
        <name>eth3</name>
        <mtu>1500</mtu>
        <status>waking up</status>
      </interface>
    </interfaces>
  </data>
</rpc-reply>
```

Appendix B. Change Log

-- RFC Ed.: remove this section before publication.

B.1. 13-14

Removed reference to RFC 4741 and using 4741bis instead.

B.2. 12-13

Removed with-defaults capability conformance section.

Changed 'wd:default' to 'default'.

Added normative reference to XSD.

Clarified conditional support for with-defaults enumerations, based on capability parameters.

Clarified that all xs:boolean encoding values must be supported.

Clarified purpose of also-supported parameter in capability URI.

B.3. 11-12

Made editorial clarifications based on AD review.

B.4. 10-11

Changed term 'database' to 'configuration datastore' or generic 'datastore'.

B.5. 09-10

Changed term 'datastore' to 'database'.

Added term 'default value'.

Clarified verbage for data node containing a default value.

B.6. 08-09

Removed non-volatile server requirements.

Moved some text from basic-mode section into the the retrieval modes section.

Added description and reference statements to the YANG module.

Many bugfixes and clarifications, based on WGLC review comments.

B.7. 07-08

Added report-all-tagged mode.

Changed conformance so report-all or report-all-tagged mode SHOULD be supported.

Clarified capability requirements for each mode, for edit-config and NV storage requirements.

Changed rpc-error details for unsupported with-defaults value.

Added XSD for wd:default attribute

Expanded example to show report-all-tagged for a basic-mode=trim server.

B.8. 06-07

Removed text in capability identifier section about adding YANG module capability URI parameters.

Changed YANG module namespace to match YANG format, and updated examples to use this new namespace.

Fixed some typos.

B.9. 05-06

Removed ':1.0' from capability URI.

Removed open issues section because all known issues are closed.

Moved examples to a separate appendix, and expanded them.

Added example.yang as an appendix to properly explain the examples used within the document.

Replaced normative term 'SHALL' with 'MUST' to be consistent within this document.

Clarified <with-defaults> behavior for non-configuration data nodes.

Clarified various sections based on WGLC comments on mailing list.

Removed some unused terms.

Reversed the order of the change log sections so the most recent changes are shown first.

B.10. 04-05

Updated I-D and YANG module boiler-plate.

Removed redundant 'with-defaults' YANG feature.

Changed definition of 'explicit' mode to match the YANG definition

Removed XSD because the YANG is normative and the XSD is unconstrained, and does not properly extend the 3 affected NETCONF operations.

Made the YANG module a normative section instead of non-normative appendix.

Changed YANG from an informative to a normative reference,

Changed 4741bis from an informative to a normative reference because the YANG module imports the ietf-netconf module in order to augment some operations.

Updated capability requirements to include YANG module capability parameters.

Added a description statement to the with-defaults leaf definition.

Update open issues section; ready to close all open issues.

B.11. 03-04

Clarifications

Added non-netconf interfaces to the definition of explicitly set default data

B.12. 02-03

Clarifications

YAM added

Use the same URN for the capability and the XML namespace to accommodate YANG, and avoid two separate URN/URIs being advertised in the HELLO message, for such a small function.

B.13. 01-02

report-all made mandatory

Placeholder for YAM added, XSD will be removed when 4741 provides the NETCONF YAM

with-defaults is valid for state data as well (if state data has a defined default which might not be so frequent). The definition of explicit was modified for state data.

B.14. 00-01

Changed value set of with-default capability and element

Added version to URI

B.15. -00

Created from draft-bierman-netconf-with-defaults-01.txt

It was decided by the NETCONF mailing list, that with-defaults should be a sub-element of each affected operation. While this violates the XSD of RFC4741 this is acceptable and follows the ideas behind NETCONF and YANG.

Hopefully it will be clarified in the 4741bis RFC whether such extensions are allowed.
