

# SNMP over (D)TLS IETF-75

Wes Hardaker  
[ietf@hardakers.net](mailto:ietf@hardakers.net)

# Overview

- Recap of Current Draft Status (-04)
- SSH Identity / securityName refresher
- (D)TLS X.509 / securityName overview
- subjectAltName details
- Other (D)TLS Considerations

# Current Draft Status

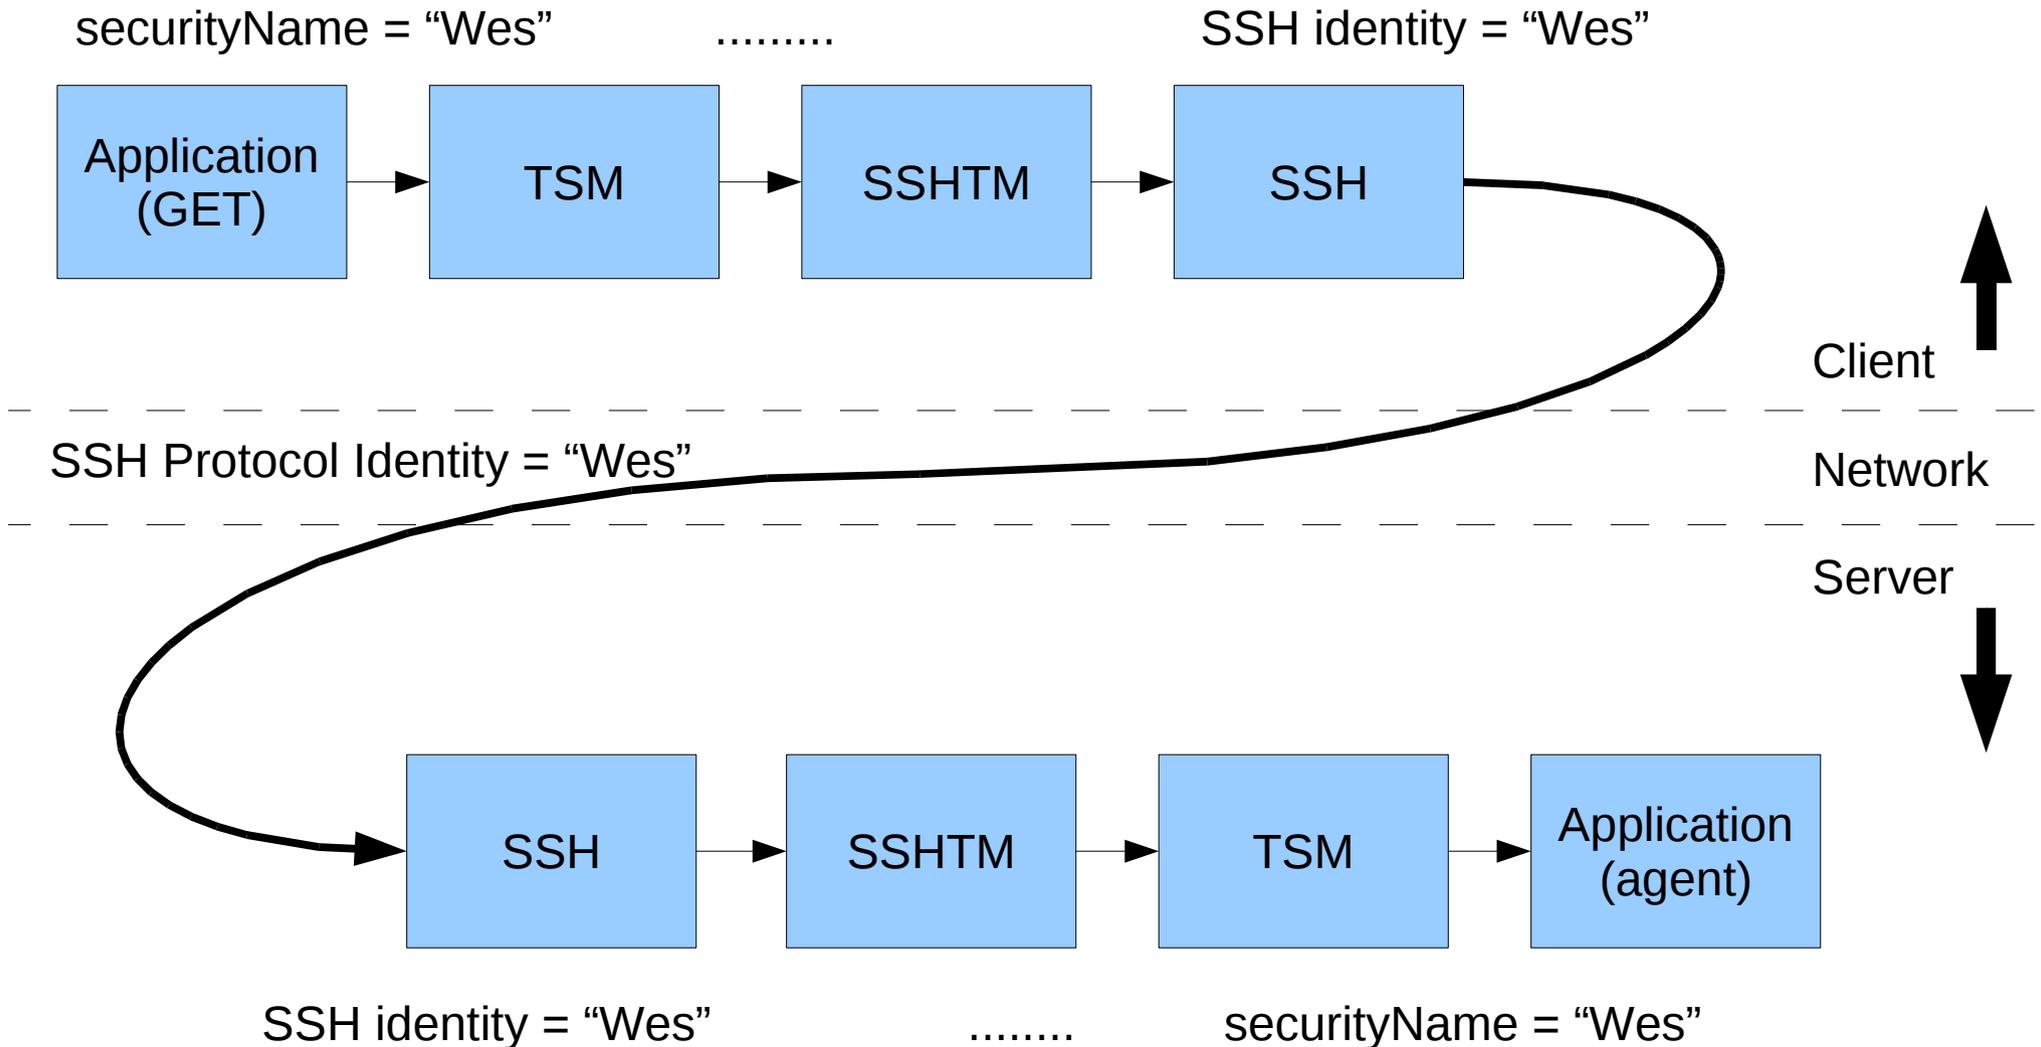

- draft-hardaker-isms-dtls-tm-04
- Updates since -03:
  - Added support for TLS
    - Brings list to TLS, DTLS/UDP and DTLS/SCTP
    - Uses (D)TLS to speak generically about any of them
    - Uses TLS or DTLS over XXX to speak about individuals
  - Other minor wording changes
- Mostly Done!
  - The biggest area for critique is the MIB tables (IMHO)
  - (and is most of the open issues to discuss today)

# Review:

## SSH Identity / securityNames

- SSH has an implicit “identity” that is sent through the protocol.
  - Maps directly to a securityName
  - Traditionally short (“login names”)
- Simple and Easy, mostly
  - TSM optionally adds a “xxxx:” prefix
  - We provide “otheruser@” prefix support to securityNames for non-1:1 mappings

# Review: SSH Identity / securityName

# Review:

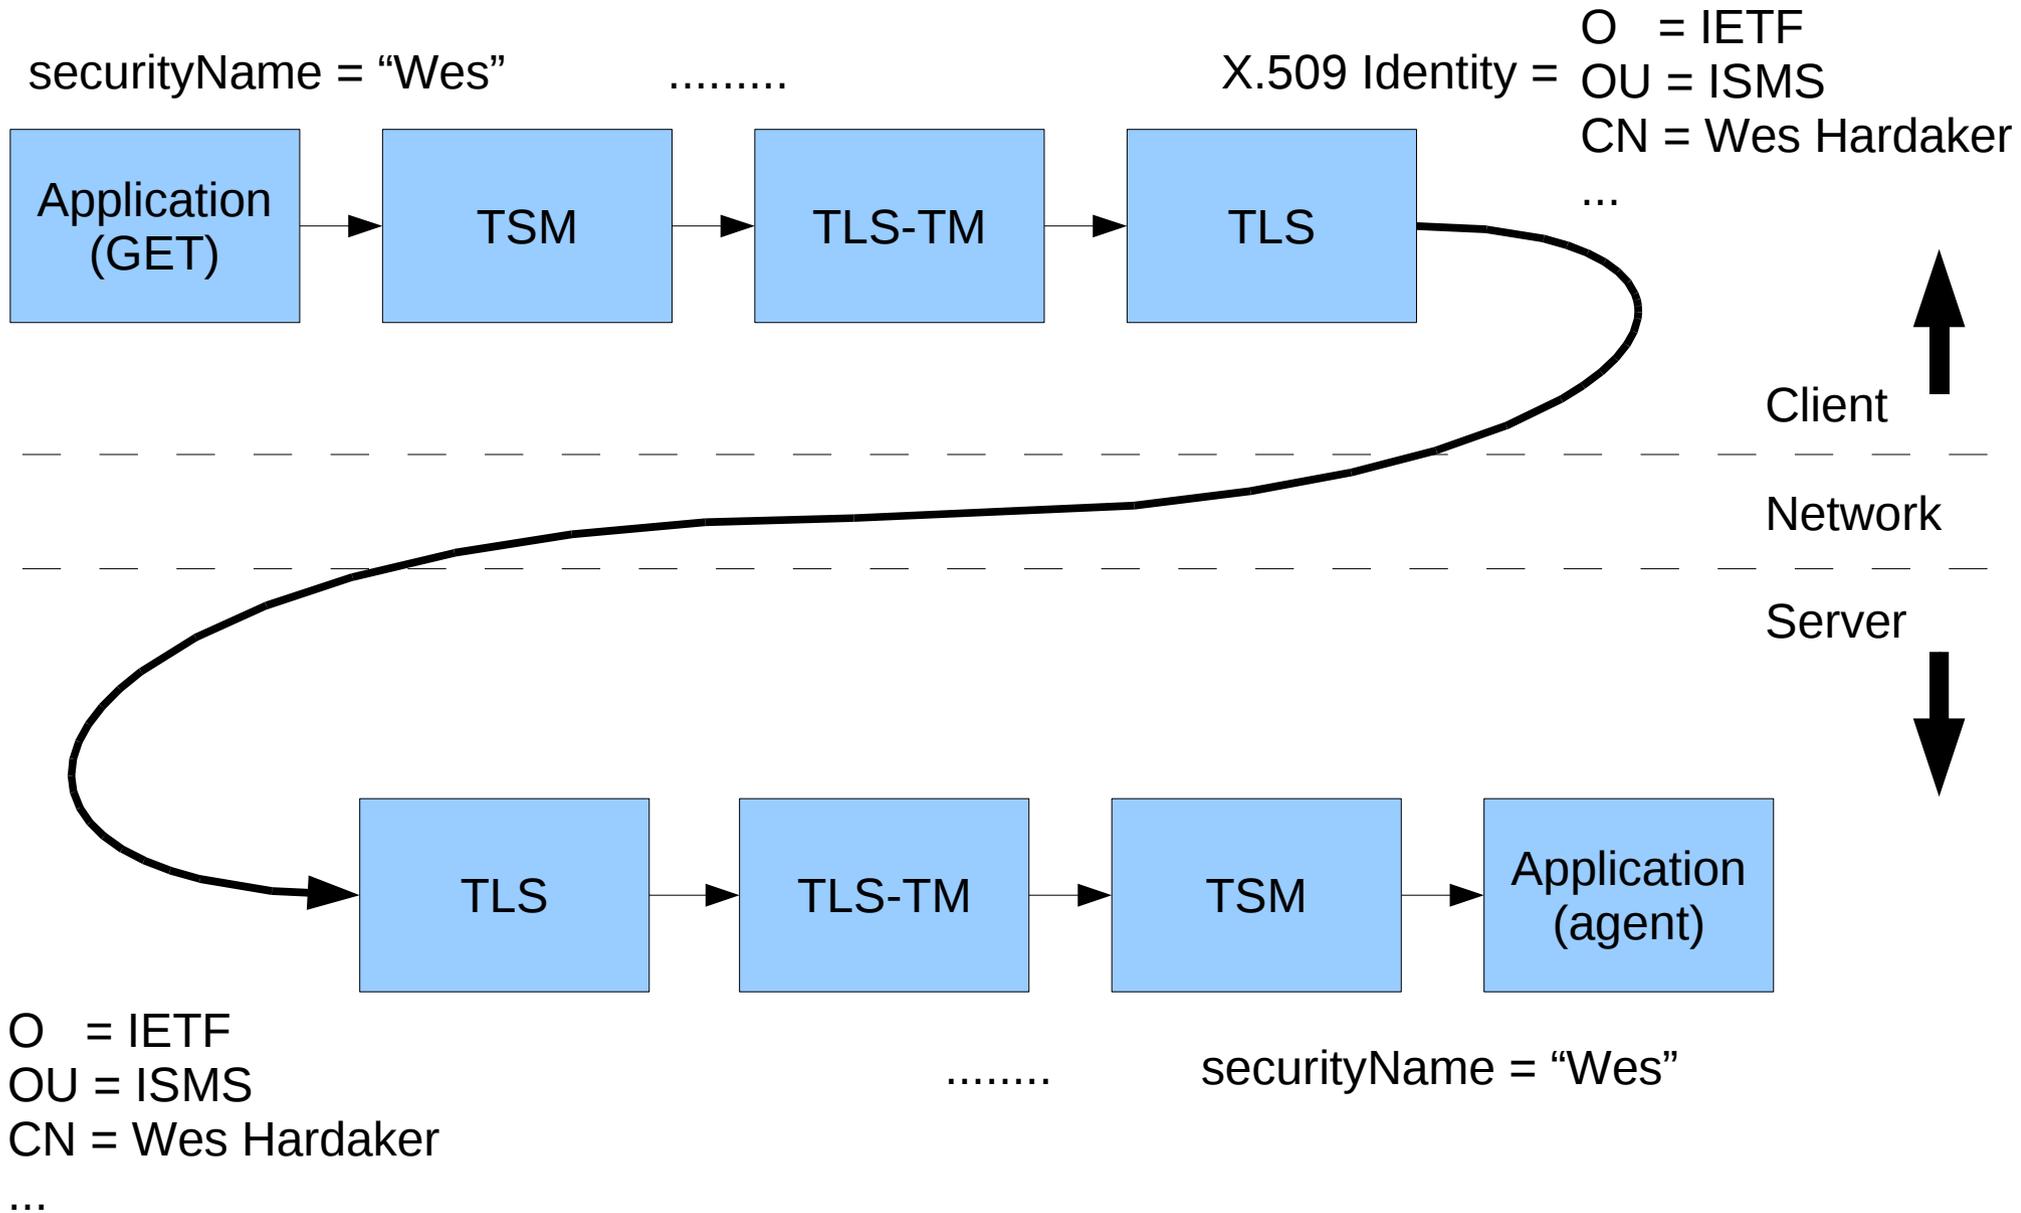

## In other words...

- SSH was fairly straight forward
- An identity string is passed directly in SSH
- ISMS relied on pre-existing SSH configuration
  - SSH already knew where user certificates were
  - SSH already knew a list of remote address and server certificate bindings were
  - IE, configuration was entirely pre-existing

# Now on to (D)TLS...

- (D)TLS is:
  - Provides no “I'm Wes” identity field
  - Uses X.509 certificate based authentication
  - Any needed identity information is expected to come from the certificate
- X.509 certificates provide a lot of data:
  - Location, Organizational Information, Name(s), ...
  - No direct easy 1:1 mapping choice

# X.509 Identity / securityName

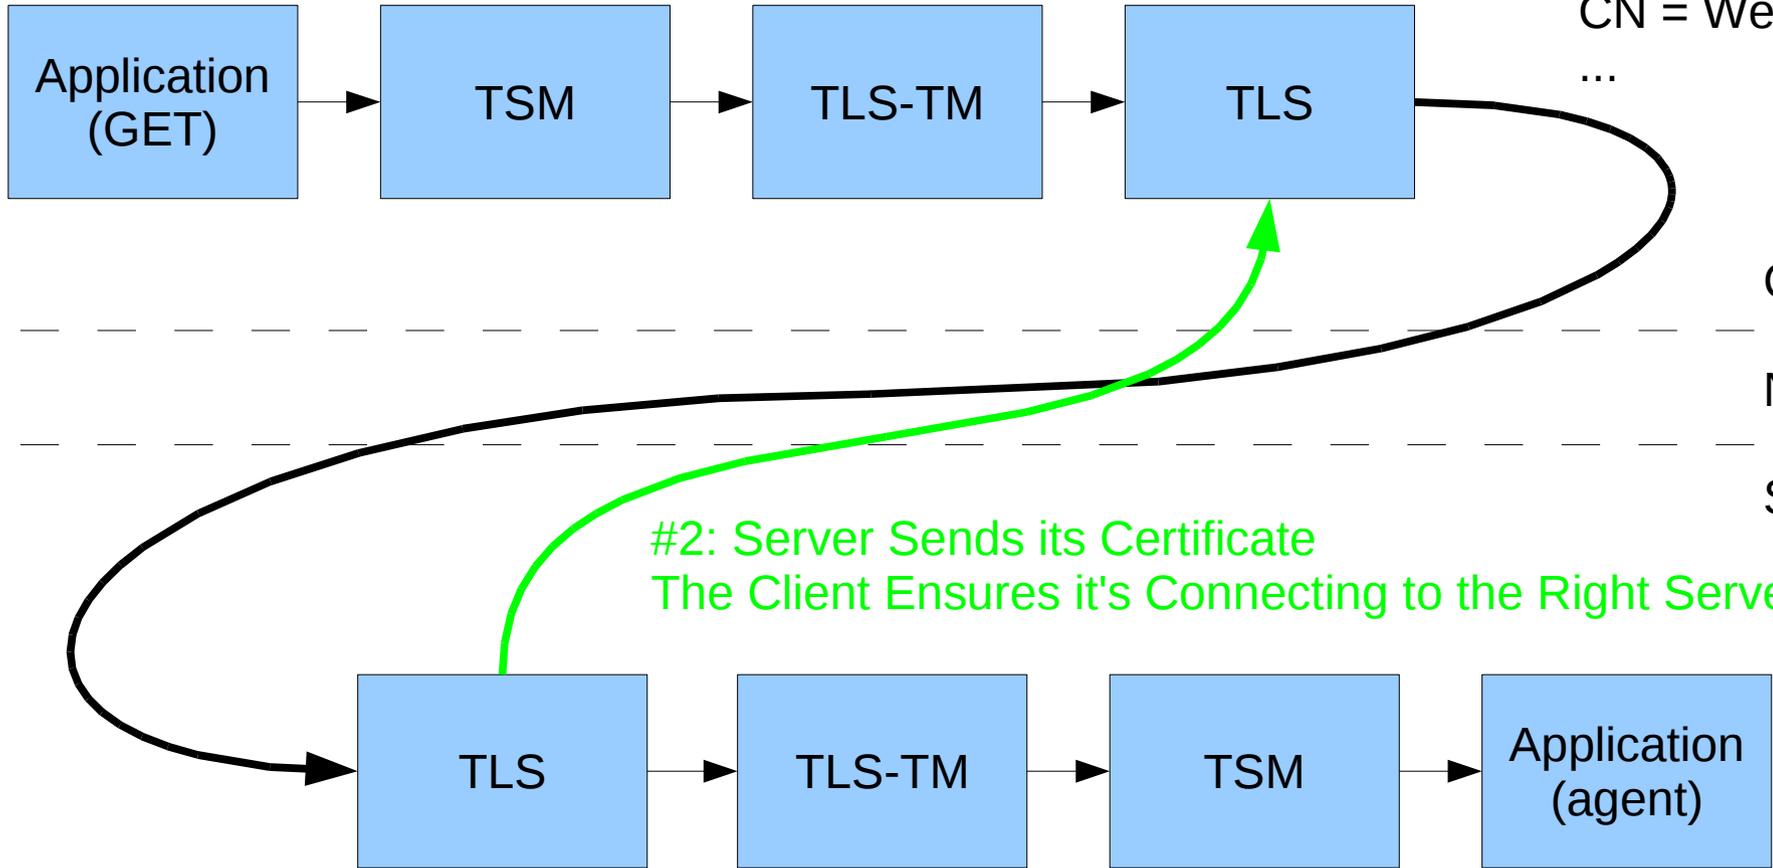

# X.509 Identity / securityName

3 issues:

#1: Client-side Mapping

securityName = "Wes"

X.509 Identity = O = IETF  
OU = ISMS  
CN = Wes Hardaker  
...

O = IETF  
OU = ISMS  
CN = Wes Hardaker  
...

securityName = "Wes"

# 3 Issues

## Client Side Certificate Usage

(1) SNMP-TARGET-MIB outputs: securityName

- Which client certificate should be used?

(2) What server certificate should be expected?

- Can I be sure I'm connecting to the right server?

## Server Side Certificate Usage

(3) How to map a client's certificate to a securityName?

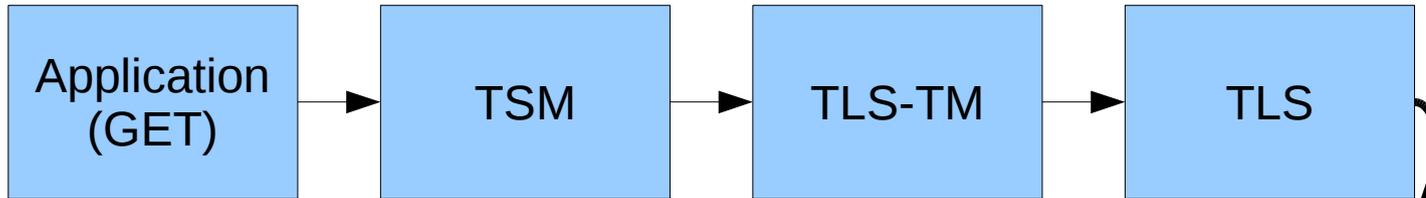

# X.509 Identity / securityName

3 issues:

#1: Client-side Mapping

securityName = "Wes"

X.509 Identity = O = IETF  
OU = ISMS  
CN = Wes Hardaker  
...

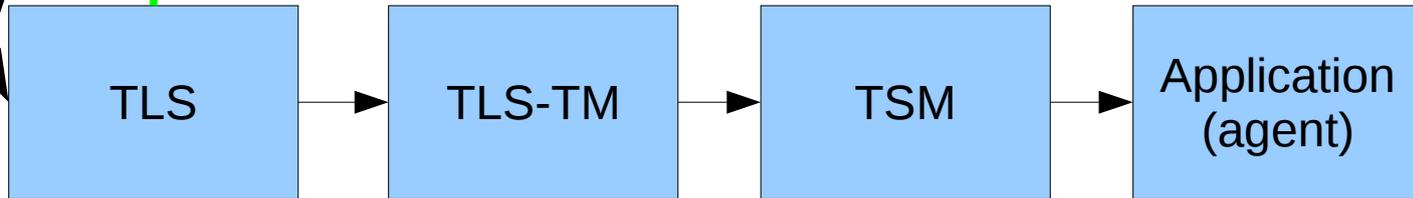

Client

Network

Server

#2: Server Sends its Certificate

The Client Ensures it's Connecting to the Right Server

O = IETF  
OU = ISMS  
CN = Wes Hardaker  
...

#3: Server-side Mapping

securityName = "Wes"

...

# (1) Client Sending: tlstmParamsTable

- Extension table to the snmpTargetParamsTable
- Adds Certificate hash type and hash value
- Used to look up a certificate in an implementation dependent certificate store
- (D)TLS connects using this certificate

# (1) Client Sending: tlstmParamsTable

- Discussed on the mailing list
  - General agreement that this was the right way to go
  - Minor disagreements about the RowStatus wording
- Believed Resolved

# X.509 Identity / securityName

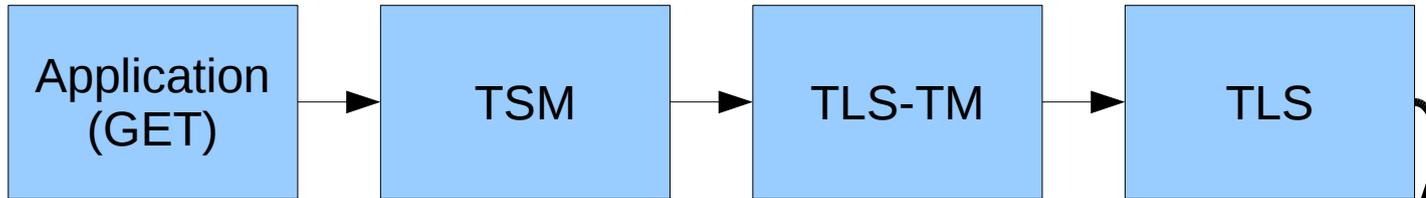

3 issues:

#1: Client-side Mapping

securityName = "Wes"

X.509 Identity =

O = IETF  
OU = ISMS  
CN = Wes Hardaker  
...

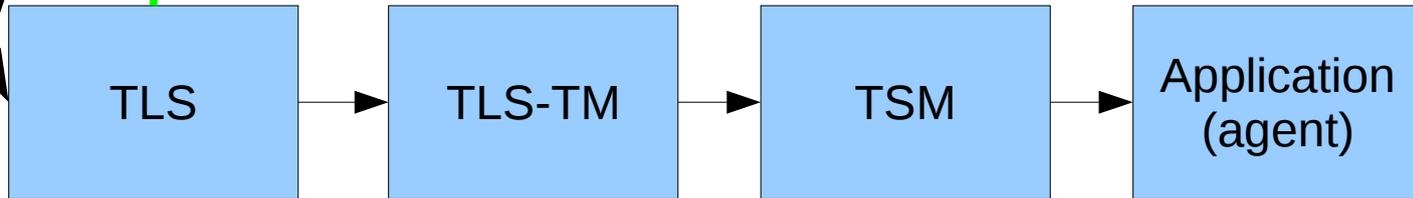

Client ↑

Network

Server ↓

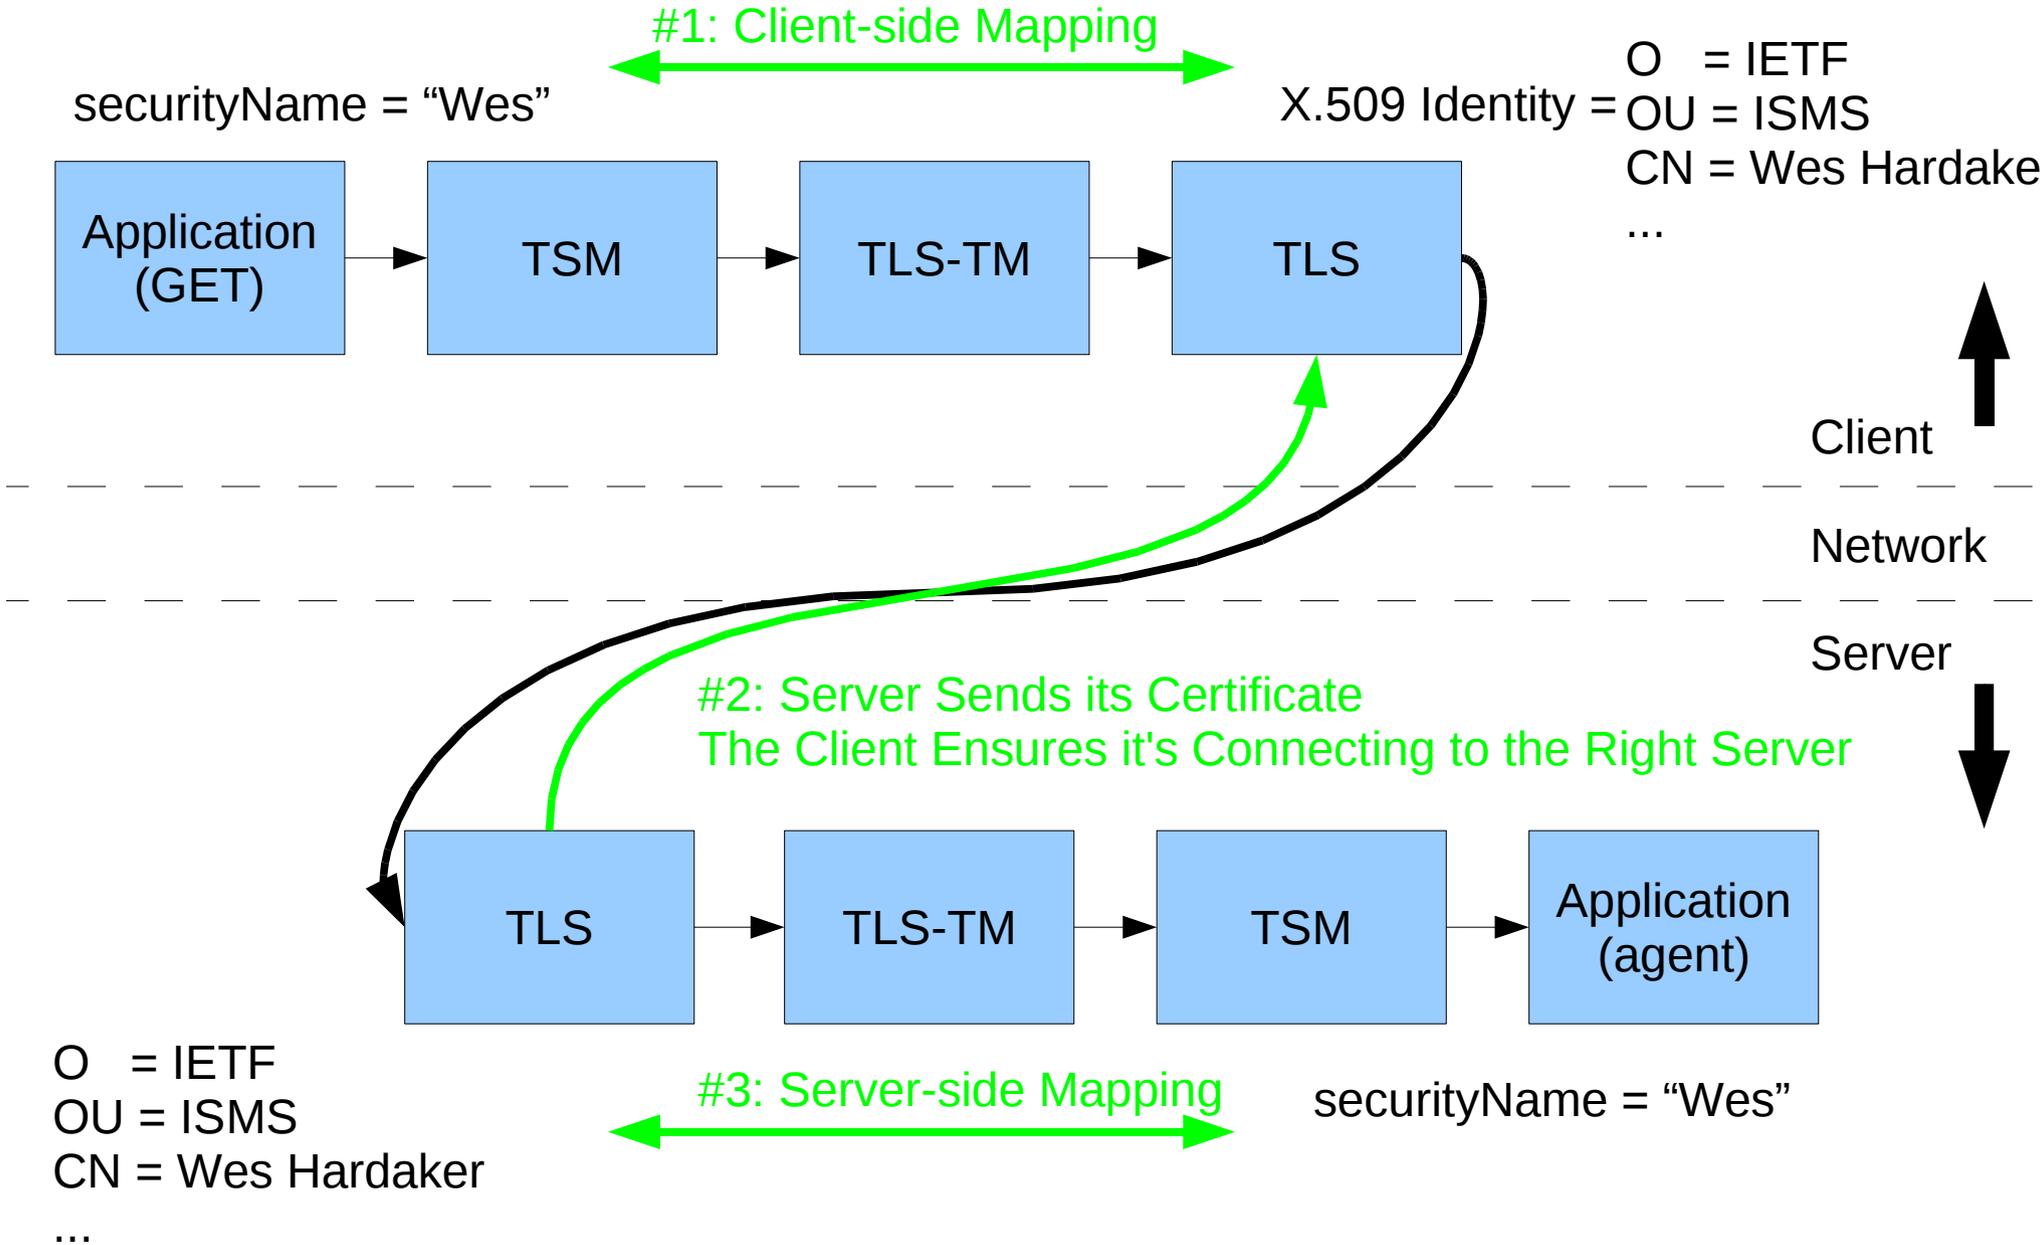

#2: Server Sends its Certificate  
The Client Ensures it's Connecting to the Right Server

O = IETF  
OU = ISMS  
CN = Wes Hardaker  
...

#3: Server-side Mapping

securityName = "Wes"

## (2) Client Receiving: Server Certificate Expectations

- In SSHTM we assumed `known_hosts` exists
- (D)TLS MAY use certificate hierarchies
- In (D)TLSTM we can:
  - a) Decide that the `CommonName` must match
    - (though common, this usage is being deprecated)
  - b) Decide that one `subjectAltName` must match
  - c) Configure a single certificate hash per server
    - (Would extend the `snmpTargetAddrTable`)
  - d) Optional a, b, and/or c
  - e) Assume something exists already

# (2) Client Receiving: Server Certificate Expectations

- Discussed on the mailing list
  - Not fully resolved?
  - Current agreement seems to be:
    - Text to discuss subjectAltName mapping
      - Our addressType needs to be converted to subjectAltName types
      - (referencing external documentation)
    - Don't standards-support but don't prohibit certificate hash per address
  - Any discussion today?

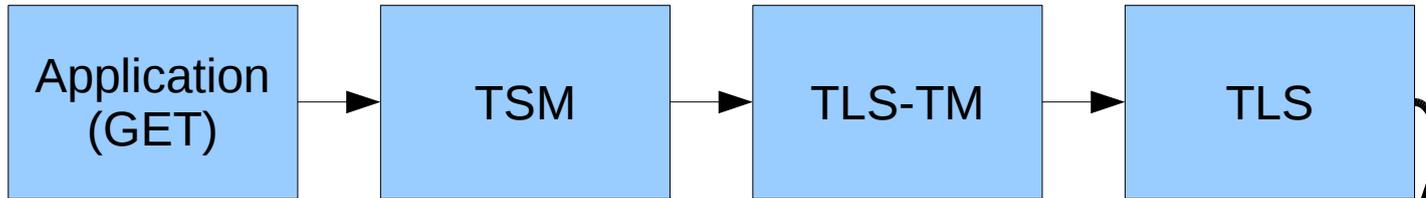

# X.509 Identity / securityName

3 issues:

#1: Client-side Mapping

securityName = "Wes"

X.509 Identity = O = IETF  
OU = ISMS  
CN = Wes Hardaker  
...

O = IETF  
OU = ISMS  
CN = Wes Hardaker  
...

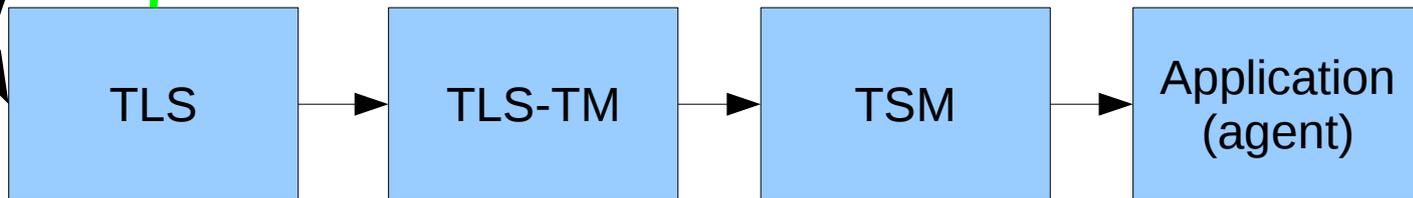

Client

Network

Server

#2: Server Sends its Certificate

The Client Ensures it's Connecting to the Right Server

O = IETF  
OU = ISMS  
CN = Wes Hardaker  
...

#3: Server-side Mapping

securityName = "Wes"

## (3) Server Receiving: Client X.509 Certificates

- Servers will receive a client's X.509 certificate
- Need to map this to a securityName
- Not yet discussed on the mailing list
- (some problems are handled by X.509 handling already, but are referenced here for education; some problems ISMS needs to handle directly)

# (3) Server Receiving: Client X.509 Certificates

- Usable X.509 Certificate Fields:
  - Direct Map (doesn't scale well)
  - CommonName (maybe long; deprecating)
  - SubjectAltName (is the future)
- Compounded By Multiple Certificate Issuers
  - Issuer1 CN="IETF", User CN="Wes"
  - Issuer2 CN="EvilHacker", User CN="Wes"
- Result:
  - A certificate to securityName system is needed
  - The good news is that a solution is fairly simple

# (3) tlstmCertificateToSNTable

- Ordered list of mapping rules
- Mapping Types:
  - Direct Certificate Hash    SN = specified string
  - TrustAnchor Hash            SN = CommonName
  - TrustAnchor Hash            SN = SubjectAltName
- Very Simple Table
  - 8 columns including index and storage/rowstatus
  - But flexible for small-nets or enterprise-wide

### (3) tlstmCertificateToSNTable

```
TlstmCertificateToSNEntry ::= SEQUENCE {  
    tlstmCertID                Unsigned32,  
    tlstmCertHashType          X509IdentifierHashType,  
    tlstmCertHashValue        X509IdentifierHash,  
    tlstmCertMapType          INTEGER { specified(1),  
                                   bySubjectAltName(2), byCN(3) },  
    tlstmCertSecurityName     SnmpAdminString,  
    tlstmCertStorageType      StorageType,  
    tlstmCertRowStatus        RowStatus  
}
```

# (3) subjectAltName Considerations

- RFC5280 SubjectAltName definition:

SubjectAltName ::= GeneralNames

GeneralNames ::= SEQUENCE SIZE (1..MAX) OF GeneralName

GeneralName ::= CHOICE {

|                           |       |                |
|---------------------------|-------|----------------|
| otherName                 | [ 0 ] | OtherName,     |
| rfc822Name                | [ 1 ] | IA5String,     |
| dNSName                   | [ 2 ] | IA5String,     |
| x400Address               | [ 3 ] | ORAddress,     |
| directoryName             | [ 4 ] | Name,          |
| ediPartyName              | [ 5 ] | EDIPartyName,  |
| uniformResourceIdentifier | [ 6 ] | IA5String,     |
| iPAddress                 | [ 7 ] | OCTET STRING,  |
| registeredID              | [ 8 ] | OBJECT IDENT } |

# subjectAltName Considerations

- Choices when looking through subjectAltNames:
  - 1) Pick first of mappable types: rfc822Name, dNSName
    - What about IP Addresses?
  - 2) Add a selection column (rfc822Name or dNSName)
    - Again, picking first found if multiple exist
  - 3) Define our own extension OID for mapping
  - 4) A combination of the above
- Draft currently does #1
- What happens when length is too long (>32)?

# Other (D)TLS Issues/Considerations

- DTLS over UDP provides no session identification
  - (resolved in draft)
  - IE, every packet that arrives on a port could belong to any session that is communicating over that port
  - DTLS-TM Rule: Must have only one session per source-addr, source-port, dest-addr, dest-port
    - (functionally requires clients to use unique port per server)
- Current draft provides a lot of overview text
  - X.509, DTLS, etc.
  - Keep or remove?

# Questions?

# Secret Slides.

- Shhhhhh
- Stop
- Don't go on.

# Certificate Mapping Options

- Don't standardize mapping (ie, no MIB tables)
  - Not a complete solution and difficult deployment
- Standardize Mapping
  - Require conforming certificates
    - (e.g. must have a subjectAltName)
    - Still requires issuer configuration and ordering
    - Reduces reuse of existing infrastructure
  - Provide mapping tables
    - Best trade off
