Thorsten Lohmar
Outline

- Introduction & Background
- Motivation
- High Level Procedures
- Examples
- Summary of features
Some background

- 3GPP defined “Fast Content Switching and Start-up” for RTSP 1.0 within 3GPP Release 7
  - Defined in 3GPP TS 26.234 (Release 7 & later) Chapter 5.5
    (http://www.3gpp.org/ftp/Specs/html-info/26234.htm)
  - Annex M contains examples for most cases

- IMTC has done successful interoperability tests for Fast Content Switching & Start-up
  - Commercial clients and servers from several vendors

- It would be good, that a similar feature is available for RTSP 2.0
Motivation for this feature

- RTSP 2.0 defines the establishment and control of a single content item using RTP

- RTSP 2.0 does not consider the consumption (or snack-ins) of several content items.
  - Example: Users “browse” through Video Portals

- The present proposal decouples the RTSP session from the actual content
  - RTSP & RTP sessions can be re-used for different content
  - Release and Establishment of RTSP & RTP sessions is avoided

- Goals:
  - Minimize Round-Trips to get new content played
  - Ensure fast content switch for most common cases without breaking the on-going streaming session
High Level Procedure

- Prerequisite: A RTSP client has established a streaming session
  - Example: the streaming session consists out of the RTSP control session, and two RTP sessions (i.e. audio & video)

- The user would like to continue with different content from the same site

- The RTSP client sends (typically) only a single RTSP PLAY message with the new content URI to the server
  - The new “Switch-Stream” header describes the replacement of the Media Control URIs
  - The RTP sessions are re-used for transport of the media components of the new content

- The states of the streaming sessions are changed to the new content

Summary of Features

- Content Switch with available Content Description (SDP)
  - The RTSP client has fetched the SDP file for the new content during an earlier transaction
  - Thus, the RTSP client knows about number of media components, codec information and media URIs
  - The RTSP client may establish RTP sessions for new content before or after the actual content switch

- Content Switch without new Content Description (SDP)
  - The RTSP client uses the URI to the SDP file to identify the content
  - The RTSP client receives the full SDP with the RTSP PLAY response
  - The RTSP client may need to add or remove RTP sessions, however, the playout may start in most cases

- Switching Media within an RTSP session
  - The content description defines e.g. multiple video tracks for F1 races
  - The RTSP client can change single media components during an ongoing session
