IETF 78
26 July 2010
• RFC 5280 currently defines two examples for how to generate key identifiers.
• Neither example is required, but <some|many> developers interpret the examples as required (the only algorithmic ways to generate key IDs)
• We want to explicitly add more methods that are similar to the example that’s already there:
  – The keyIdentifier is composed of the least significant 160-bits of the SHA-224/256/384/512 hash of the value of the BIT STRING subjectPublicKey (excluding the tag, length, and number of unused bits).
Comments

• We also could add a qualifier/type identifier for folks who want to know how the key ID was generated
• We could add a new extension to indicate the qualification, but that is a separate question
• We do NOT propose putting any bits in the current extensions (AKI/SKI) to indicate the hash algorithm used to generate the ID
Way Ahead

• Adopt as WG item?
