NEA Asokan Attack Analysis  
draft-salowey-nea-asokan-00.txt

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/lid-abstracts.txt>

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>

This Internet-Draft will expire on April 18, 2011.

## 1. Introduction

The Network Endpoint Assessment protocols are subject to a subtle forwarding attack that has become known as the NEA Asokan Attack. This document describes the attack and countermeasures that may be mounted.

This document is not intended to formally define a protocol but rather to explore the options for countering the Asokan attack. The NEA WG is expected to consider these options, decide which to select, and incorporate specific text defining that option into a Standards Track document. Then this document will be allowed to expire.

## 2. NEA Asokan Attack Explained

The NEA Asokan Attack is a variation on an attack described in a 2002 paper written by Asokan, Niemi, and Nyberg [1]. Figure 1 depicts one version of the original Asokan attack. This attack

involves tricking an authorized user into authenticating to a decoy AAA server, which forwards the authentication protocol from one tunnel to another, tricking a AAA server into believing these messages came from the attacker and granting access to him.

Figure 1: One Example of Original Asokan Attack

As described in the NEA Overview [2], the NEA Reference Model is composed of several nested protocols. The PA protocol is nested in the PB protocol, which is nested in the PT protocol. When used together successfully, these protocols allow a NEA Server to assess the security posture of an endpoint. The NEA Server may use this information to decide whether network access should be granted or for other purposes.

Figure 2 illustrates a NEA Asokan Attack. The attacker wants to trick GoodServer into believing that DirtyEndpoint has good security posture. This might allow the attacker to bring an infected machine onto a network and infect others, for example. To accomplish this goal, the attacker forwards PA messages from CleanEndpoint through BadServer to DirtyEndpoint, which sends them on to GoodServer. GoodServer is tricked into thinking that the PA messages came from DirtyEndpoint and therefore considers DirtyEndpoint to be clean.

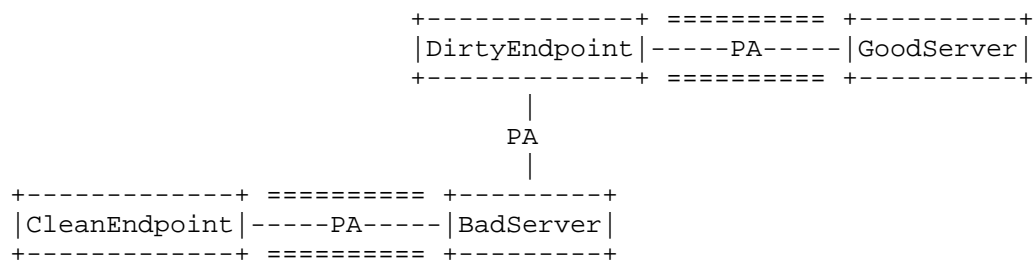

Figure 2: NEA Asokan Attack

Countermeasures against a NEA Asokan Attack are described in section 4.

### 3. Lying Endpoints

Some may argue that there are other attacks against NEA systems that are simpler than the Asokan attack, such as lying endpoint attacks. That is true. It's easy for an endpoint to simply lie about its posture. But there are defenses against lying endpoint attacks, such as using an external measurement agent (EMA).

An EMA is hardware, software, or firmware designed to accurately report on endpoint configuration but be especially secure and hard to compromise. The EMA observes and reports on critical aspects of endpoint posture such as which security-relevant firmware and software has been loaded.

When an EMA is used for NEA, the PA messages that reliably and securely establish endpoint posture are exchanged between the EMA itself and a Posture Validator on the NEA Server. The Posture Collector on the endpoint and any other intermediaries between the EMA and the Posture Validator on the NEA Server are not trusted. They just pass messages along as untrusted intermediaries.

To ensure that the EMA's messages are accurately conveyed to the Posture Validator even if the Posture Collector or other intermediaries have been compromised, these PA messages must provide integrity protection, replay protection, and source authentication between the EMA and the Posture Validator. Confidentiality protection is not needed, at least with respect to the software on the endpoint. But integrity protection should include protection against message deletion and session truncation. Organizations that have developed EMAs have typically developed remote attestation protocols that provide these properties. While the development of lying endpoint detection technologies is out of scope for NEA, these technologies must be supported by the NEA protocols.

## 4. Countermeasures Against The NEA Asokan Attack

### 4.1. Identity Binding

One way to mitigate the Asokan attack is to bind the identities used in tunnel establishment into a cryptographic exchange at the PA layer. While this can go a long way to preventing the attack it does not bind the exchange to a specific TLS exchange, which is desirable. In addition, there is no standard way to extract an

identity from a TLS session, which could make implementation difficult.

#### 4.2. Cryptographic Binding

One way to thwart the NEA Asokan Attack is for the PA exchange to be cryptographically bound to the PT exchange and to any keying material or privileges granted as a result of these two exchanges. This allows the NEA Server to ensure that the PA messages pertain to the same endpoint as the party terminating the PT exchange and that no other party gains any access or advantage from this exchange.

##### 4.2.1. Binding Options

This section discusses binding protocol solution options and provides analysis. Since the proposals for both L2 and L3 PT involve TLS the document focuses on TLS based solutions that can work with either transport.

###### 4.2.1.1. Information from the TLS Tunnel

The TLS handshake establishes cryptographic state between the TLS client and TLS server. There are several mechanisms that can be used to export information derived from this state. The client and server independently include this information in calculations to bind the instance of the tunnel into the PA protocol.

Keying Material Export - RFC 5705 [5] defines Keying Material Exporters for TLS that allow additional secret key material to be extracted from the TLS master secret.

tls-unique Channel Binding Data - RFC 5929 [6] defines several quantities that can be extracted from the TLS session to bind the TLS session to other protocols. The tls-unique binding consists of data extracted from the TLS handshake finished message.

###### 4.2.1.2. TLS Cipher Suites

In order to eliminate the possibility of a man-in-the-middle and thwart the Asokan attack it is important that neither TLS endpoint be in sole control of the TLS pre-master secret. Cipher suites based on key transport such as RSA cipher suites do not meet this requirement, instead Diffie-Hellman Cipher Suites, such as RSA-DHE, are required when this mechanism is employed.

#### 4.2.1.3. Using Additional Key Material from TLS

In some cases key material is extracted from the TLS tunnel and used to derive ciphering keys used in another protocol. For example, EAP-TLS [7] uses key material extracted from TLS in lower layer ciphering. In this case the extracted keys must not be under the control of a single party so the considerations in the previous section are important.

#### 4.2.1.4. EMA assumptions

The EMA needs to obtain the binding data from the TLS exchange and prove knowledge of the binding data in an exchange that has integrity protection, source authentication and replay protection.

### 5. Conclusions

The recommendations for addressing the Asokan attack are as follows:

1. Make use of cryptographic binding, however binding identities of the tunnel endpoints in the EMA may be useful.
2. The same mechanism be used in L2 and L3 PT transports that make use of TLS.
3. Neither TLS endpoint can be in sole control of the TLS pre-master secret.
4. The preferred approach is to use secret key material exported from the TLS handshake using the mechanism defined in RFC 5705. The key material is exported using a standardized label and made available to the EMA that will use it.

### 6. IANA Considerations

This document has no actions for IANA.

### 7. Security Considerations

This document is primarily concerned with analyzing and proposing countermeasures for the NEA Asokan Attack. That does not mean that it covers all the possible attacks against the NEA protocols or against the NEA Reference Model. For a broader security analysis, see the Security Considerations section of the NEA Overview [2], PA-TNC [3], and PB-TNC [4].

## 9. Acknowledgments

The members of the NEA Asokan Design Team were critical to the development of this document: Nancy Cam-Winget, Steve Hanna, Joe Salowey, and Paul Sangster.

The authors would also like to recognize N. Asokan, Valtteri Niemi, and Kaisa Nyberg who published the original paper on this type of attack and Pasi Eronen who extended this attack to NEA protocols in the TNC.

This document was prepared using 2-Word-v2.0.template.dot.
