Extending YANG with Language Abstractions  
draft-linowski-netmod-yang-abstract-04

Abstract

YANG - the NETCONF Data Modeling Language - supports modeling of a tree of data elements that represent the configuration and runtime status of a particular network element managed via NETCONF. This memo suggests to enhance YANG with supplementary modeling features and language abstractions with the aim to improve the model extensibility and reuse.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 22, 2011.

## 1. Introduction

YANG - the NETCONF Data Modeling Language ([RFC6020]) - supports modeling of a tree of data elements that represent the configuration and runtime status of a particular network element managed via NETCONF. This document defines extensions for the modeling language YANG as new language statements, which introduce language abstractions to improve the model extensibility and reuse. A model example from an actual network management system is given to highlight the value of proposed language extensions, especially class inheritance and recursiveness. The language extensions defined in this document have been implemented with two open source tools. These tools have been used to validate the model examples through the document.

### 1.1. Key Words

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14, [RFC2119].

### 1.2. Motivation

- o Many systems today have a management information base that in effect is organized as a tree build of recursively nested container nodes. For example, the physical resources in the ENTITY-MIB conceptually form a containment tree. The index entPhysicalContainedIn points to the containing entity in a flat list. The ability to represent nested, recursive data structures of arbitrary depth would enable the representation of the primary containment hierarchy of physical entities as a node tree in the server MIB and in the NETCONF payload.
- o A manager scanning the network in order to update the state of an inventory management system might be only interested in data structures that represent a specific type of hardware. Such a manager would then look for entities that are of this specific type, including those that are an extension or specialization of this type. To support this use case, it is helpful to bear the corresponding type information within the data structures, which describe the network element hardware.
- o A system that is managing network elements is concerned e.g. with managed objects of type "plug-in modules" that have a name, a version and an activation state. In this context, it is useful to define the "plug-in module" as a concept that is supposed to be further detailed and extended by additional concrete model

elements. In order to realize such a system, it is worth to model abstract entities, which enable reuse and ease concrete refinements of that abstract entity in a second step.

- o As particular network elements have specific type of components that need to be managed (OS images, plug-in modules, equipment, etc.), it should be possible to define concrete types, which describe the managed object precisely. By using type-safe extensions of basic concepts a system in the manager role can safely and explicitly determine that e.g. the "equipment" is actually of type "network card".
- o Currently different SDOs are working on the harmonization of their management information models. Often a model mapping or transformation between systems becomes necessary. The harmonization of the models is done e.g. by mapping of the two models on object level or integrating an object hierarchy into an existing information model. Extending YANG with language abstractions can simplify on the one hand the adoption of IETF resource models by other SDOs and facilitate the alignment with other SDO's resource models (e.g. TM Forum SID). The proposed YANG extensions can on the other hand enable the utilization of YANG modeling language in other SDOs, which are used to model complex management systems in a top-down manner and use high-level language features frequently.

This memo specifies additional modeling features for the YANG language in the area of structured model abstractions, typed references as well as recursive data structures and discusses how these new features can improve the modeling capabilities of YANG.

Section 1.5.1 contains a physical resource model, which deals with some of the modeling challenges illustrated above. Section 1.5.2 gives an example, which uses the base classes defined in the physical resource model and derives a model for physical entities defined in Entity MIB".

### 1.3. Modeling Improvements with Language Abstractions

Complex Types and Typed Instance Identifiers provide various technical improvements on modeling level:

- o In case the model of a system that should be managed with NETCONF makes use of inheritance, complex types enable an almost one-to-one mapping between the classes in the original model and the YANG module.

- o Typed instance identifiers allow representing associations between the concepts in a type-safe way to prevent type errors caused by referring to data nodes of incompatible types. This avoids referring to a particular location in the MIB, which is not mandated by the domain model.
- o Complex types allow defining complete, self-contained type definitions. It is not necessary to explicitly add a key statement to lists, which use a grouping defining the data nodes.
- o Complex types simplify concept refinement by extending a base complex type and make it superfluous to represent concept refinements with workarounds such as huge choice-statements with complex branches.
- o Abstract complex types ensure correct usage of abstract concepts by enforcing the refinement of common set of properties before instantiation.
- o Complex types allow defining recursive structures. This enables to represent complex structures of arbitrary depth by nesting instances of basic complex types that may contain themselves.
- o Complex types avoid introducing meta-data types (e.g. type code enumerations) and meta-data leafs (e.g. leafs containing a type code) to indicate, which concrete type of object is actually represented by a generic container in the MIB. This also avoids to explicitly rule out illegal use of sub-type specific properties in generic containers.
- o Complex type instances include the type information in the NETCONF payload. This allows to determine the actual type of an instance during the NETCONF payload parsing and avoids the use of additional leafs in the model, which provide the type information as content.
- o Complex types may be declared explicitly as optional features, which is not possible when the actual type of an entity represented by a generic container is indicated with a type code enumeration.

Appendix C 'Example YANG Module for the IPFIX/PSAMP Model' lists technical improvements for modeling with Complex Types and Typed Instance Identifiers and exemplifies the usage of the proposed YANG extensions based on the IPFIX/PSAMP configuration model in [IPFIXCONF].

## 1.4. Design Approach

The proposed additional features for YANG in this memo are designed to reuse existing YANG statements whenever possible. Additional semantics is expressed by an extension that is supposed to be used as a substatement of an existing statement.

The proposed features don't change the semantics of models that are valid with respect to the YANG specification [RFC6020].

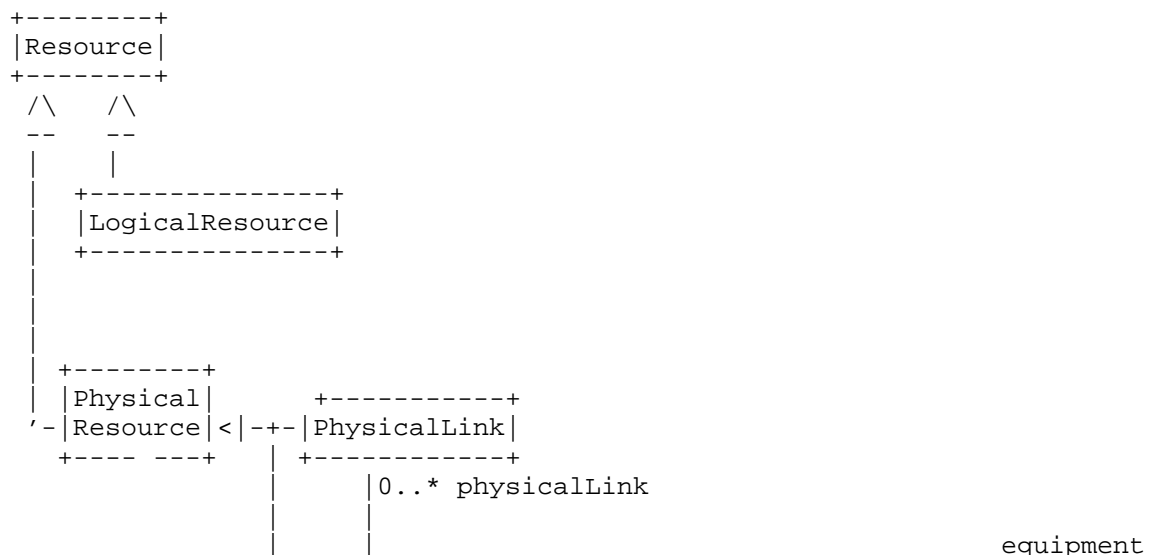

## 1.5. Modeling Resource Models with YANG

### 1.5.1. Example of a Physical Network Resource Model

The diagram below depicts a portion of an information model for manageable network resources used in an actual network management system.

Note: The referenced model (UDM, Unified Data Model) is based on key resource modelling concepts from [SID V8] and is compliant with selected parts of SID Resource Abstract Business Entities domain ([UDM]).

The class diagram in Figure 1 and the according YANG module excerpt focus on basic resource ("Resource" and the distinction between logical- and physical resources) and hardware abstractions ("Hardware", "Equipment", and "EquipmentHolder"). Some class attributes were omitted to achieve decent readability.

Figure 1: Physical Network Resource Model

Since this model is an abstraction of network element specific MIB topologies, modeling it with YANG creates some challenges. Some of these challenges and how they can be addressed with complex types are explained below:

- o Modeling of abstract concepts: Classes like "Resource" represent concepts that primarily serve as a base class for derived classes. With complex types, such an abstract concept could be represented by an abstract complex type (see "complex-type extension statement" and "abstract extension statement").
- o Class Inheritance: Information models for complex management domains often use class inheritance to create specialized classes

like "PhysicalConnector" from a more generic base class (here "Hardware"), which itself might inherit from another base class ("PhysicalResource") etc. Complex types allow creating enhanced versions of an existing (abstract or concrete) base type via an extension (see "extends extension statement").

- o Recursive containment: In order to specify containment hierarchies models frequently contain different aggregation associations, in which the target (contained element) is either the containing class itself or a base class of the containing class. In the model above, the recursive containment of "EquipmentHolder" is an example of such a relationship. Complex types support such a containment by using a complex type (or one of its ancestor types) as type of an instance or instance list that is part of its definition (see "instance(-list) extension statement").
- o Reference relationships: A key requirement on large models for network domains with many related managed objects is the association between classes that represent an essential relationship between instances of such a class. For example, the relationship between "PhysicalLink" and "Hardware" tells which physical link is connecting which hardware resources. It is important to notice that this kind of relationships do not mandate any particular location of the two connected hardware instances in any MIB. Such containment agnostic relationships can be represented by a typed instance identifier that embodies one direction of such an association (see "Typed instance identifiers").

The YANG module excerpt below shows how the challenges listed above can be addressed by the Complex Types extension (module import prefix "ct:"). The complete YANG module for the physical resource model in Figure 1 can be found in Appendix B: 'YANG Modules for Physical Network Resource Model and Hardware Entities Model'.

Note: The YANG extensions proposed in this document have been implemented as the open source tools "Pyang Extension for Complex Types" ([Pyang-ct], ([Pyang]) and "Libsmi Extension for Complex Types" ([Libsmi]). All model examples in the document have been validated with the tools Pyang-ct and Libsmi.

<CODE BEGINS>

```
module udmcore {  
  
    namespace "http://example.com/udmcore";
```

```
prefix "udm";

import ietf-complex-types {prefix "ct"; }

    // Basic complex types...

ct:complex-type PhysicalResource {
  ct:extends Resource;
  ct:abstract true;
  // ...
  leaf serialNumber {type string;}
}

ct:complex-type Hardware {
  ct:extends PhysicalResource;
  ct:abstract true;
  // ...
  leaf-list physicalLink {
    type instance-identifier {ct:instance-type PhysicalLink;}
  }
  ct:instance-list containedHardware {
    ct:instance-type Hardware;
  }
}

ct:instance-list physicalConnector {
  ct:instance-type PhysicalConnector;
}

ct:complex-type PhysicalLink {
  ct:extends PhysicalResource;
  // ...
  leaf-list hardware {
    type instance-identifier {ct:instance-type Hardware;}
  }
}

ct:complex-type ManagedHardware {
  ct:extends Hardware;
  ct:abstract true;
  // ...
}

ct:complex-type PhysicalConnector {
  ct:extends Hardware;
```

```
        leaf location {type string;}
        // ...
    leaf-list sourcePhysicalConnector {
        type instance-identifier {ct:instance-type PhysicalConnector;}
    }
    leaf-list targetPhysicalConnector {
        type instance-identifier {ct:instance-type PhysicalConnector;}
    }
}

ct:complex-type Equipment {
    ct:extends ManagedHardware;
    // ...
    ct:instance-list equipment {
        ct:instance-type Equipment;
    }
}

ct:complex-type EquipmentHolder {
    ct:extends ManagedHardware;
    leaf vendorName {type string;}
    // ...
    ct:instance-list equipment {
        ct:instance-type Equipment;
    }
    ct:instance-list equipmentHolder {
        ct:instance-type EquipmentHolder;
    }
}
// ...
}

<CODE ENDS>
```

#### 1.5.2. Modeling Entity MIB Entries as Physical Resources

The physical resource module described above can now be used to model physical entities as defined in the Entity MIB [RFC4133]. For each physical entity class listed in the "PhysicalClass" enumeration, a complex type is defined. Each of these complex types extends the most specific complex type already available in the physical resource module. For example, the type "HWModule" extends the complex type "Equipment" as a hardware module. Physical entity properties that should be included in a physical entity complex type are combined in a grouping, which is then used in each complex type definition of an entity.

This approach has following benefits:

- o The definition of the complex types for hardware entities becomes compact as many of the features can be reused from the basic complex type definition.
- o Physical entities are modeled in a consistent manner as predefined concepts are extended.
- o Entity MIB specific attributes as well as vendor specific attributes can be added without having to define separate extension data nodes.

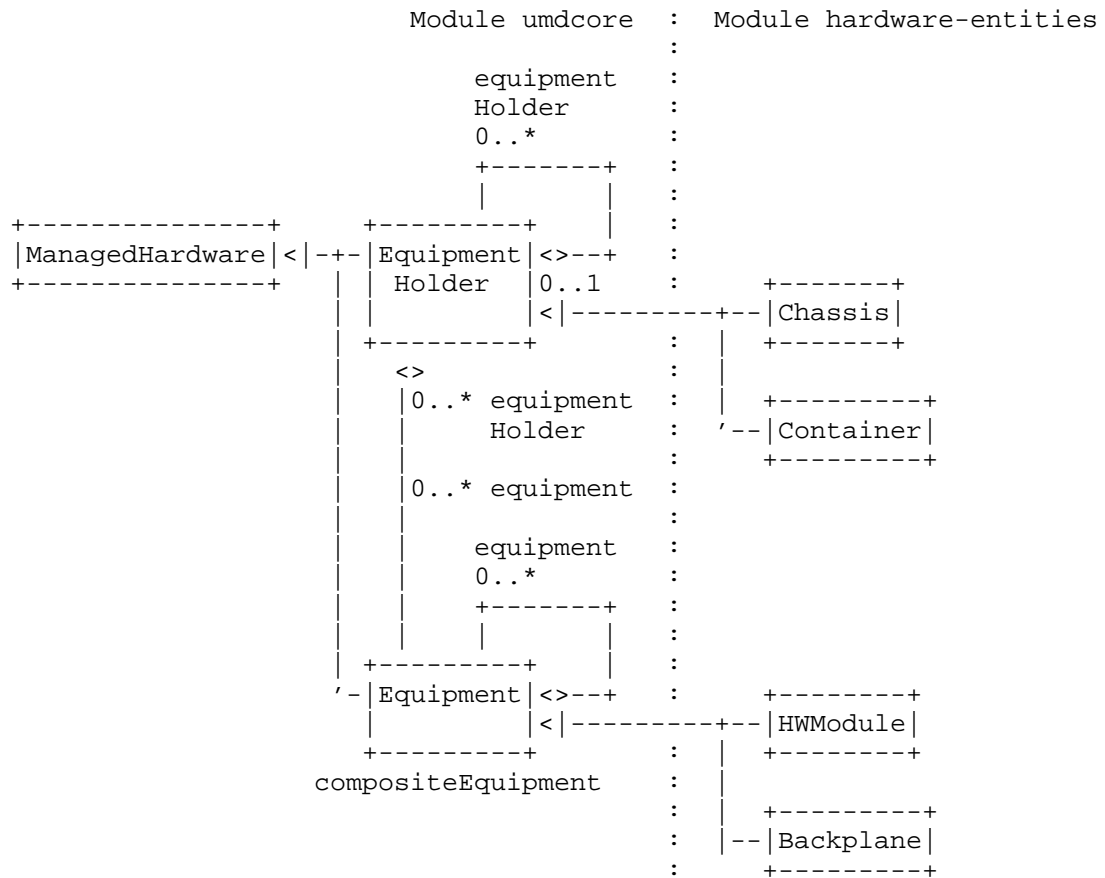

Figure 2: Hardware Entities Model

Below is an excerpt of the according YANG module using complex types to model hardware entities. The complete YANG module for the Hardware Entities model in Figure 2 can be found in Appendix B: 'YANG Modules for Physical Network Resource Model and Hardware Entities Model'.

&lt;CODE BEGINS&gt;

```
module hardware-entities {

    namespace "http://example.com/hardware-entities";
    prefix "hwe";

    import ietf-yang-types {prefix "yt";}
    import ietf-complex-types {prefix "ct";}
    import udmcore {prefix "uc";}

    grouping PhysicalEntityProperties {
        // ...
        leaf mfgDate {type yang:date-and-time; }
        leaf-list uris {type string; }
    }

    // Physical entities representing equipment

    ct:complex-type HWModule {
        ct:extends uc:Equipment;
        description "Complex type representing module entries
                    (entPhysicalClass = module(9)) in entPhysicalTable";
        uses PhysicalEntityProperties;
    }

    // ...

    // Physical entities representing equipment holders

    ct:complex-type Chassis {
        ct:extends uc:EquipmentHolder;
        description "Complex type representing chassis entries
                    (entPhysicalClass = chassis(3)) in entPhysicalTable";
        uses PhysicalEntityProperties;
    }

    // ...
}

<CODE ENDS>
```

## 2. Complex Types

### 2.1. Definition

YANG type concept is currently restricted to simple types, e.g. restrictions of primitive types, enumerations or union of simple types.

Complex types are types with a rich internal structure, which may be composed of substatements defined in Table 1 (e.g. lists, leafs, containers, choices). A new complex type may extend an existing complex type. This allows providing type-safe extensions to existing YANG models as instances of the new type.

Complex types have the following characteristics:

- o Introduction of new types, as a named, formal description of a concrete manageable resource as well as abstract concepts.
- o Types can be extended, i.e. new types can be defined by specializing existing types adding new features. Instances of such an extended type can be used wherever instances of the base type may appear.
- o The type information is made part of the NETCONF payload in case a derived type substitutes a base type. This enables easy and efficient consumption of payload elements representing complex type instances.

### 2.2. complex-type extension statement

The extension statement "complex-type" is introduced that accepts an arbitrary number of node tree defining statements among other common YANG statements ("YANG Statements", [RFC6020] Section 7).

substatement	cardinality
abstract	0..1
anyxml	0..n
choice	0..n
container	0..n
description	0..1
ct:instance	0..n
ct:instance-list	0..n
ct:extends	0..1
grouping	0..n
if-feature	0..n
key	0..1
leaf	0..n
leaf-list	0..n
list	0..n
must	0..n
ordered-by	0..n
reference	0..1
refine	0..n
status	0..1
typedef	0..n
uses	0..n

Table 1: complex-type's substatements

Complex type definitions may appear at every place, where a grouping may be defined. That includes the module, submodule, rpc, input, output, notification, container, and list statements.

Complex type names populate a distinct namespace. As with YANG groupings, it is possible to define a complex type and a data node (e.g. leaf, list, instance statements) with the same name in the same scope. All complex type names defined within a parent node or at the top-level of the module or its submodules share the same type identifier namespace. This namespace is scoped to the parent node or module.

A complex type MAY have an instance key. An instance key is either defined with the "key" statement as part of the complex type or is inherited from the base complex type. It is not allowed to define an additional key if the base complex type or one of its ancestors already defines a key.

Complex-type definitions do not create nodes in the schema tree.

### 2.3. instance extension statement

The "instance" extension statement is used to instantiate a complex type by creating a subtree in the management information node tree. The instance statement takes one argument that is the identifier of the complex type instance. It is followed by a block of substatements.

The type of the instance is specified with the mandatory "ct:instance-type" substatement. The type of an instance **MUST** be a complex type. Common YANG statements may be used as substatements of the "instance" statement. An instance is by default optional. To make an instance mandatory, "mandatory true" has to be applied as substatement.

substatement	cardinality
description	0..1
config	0..1
ct:instance-type	1
if-feature	0..n
mandatory	0..1
must	0..n
reference	0..1
status	0..1
when	0..1
anyxml	0..n
choice	0..n
container	0..n
ct:instance	0..n
ct:instance-list	0..n
leaf	0..n
leaf-list	0..n
list	0..n

Table 2: instance's substatements

The "instance" and "instance-list" extension statements (see Section 2.4 "instance-list extension statement") are similar to the existing "leaf" and "leaf-list" statements, with the exception that the content is composed of subordinate elements according to the instantiated complex type.

It is also possible to add additional data nodes by using the according leaf, leaf-list, list, and choice statements etc. as substatements of the instance declaration. This is an in-place

augmentation of the used complex type confined to a complex type instantiation (see also Section 2.13 "Using complex types" for details on augmenting complex types).

#### 2.4. instance-list extension statement

The "instance-list" extension statement is used to instantiate a complex type by defining a sequence of subtrees in the management information node tree. In addition, the "instance-list" statement takes one argument that is the identifier of the complex type instances. It is followed by a block of substatements.

The type of the instance is specified with the mandatory "ct:instance-type" substatement. In addition it can be defined how often an instance may appear in the schema tree by using the min-elements and max-elements substatements. Common YANG statements may be used as substatements of the "instance-list" statement.

In analogy to "instance" statement, sub-statement like "list", "choice", leaf" etc. MAY be used to augment the instance list elements at the root level with additional data nodes.

substatement	cardinality
description	0..1
config	0..1
ct:instance-type	1
if-feature	0..n
max-elements	0..1
min-elements	0..1
must	0..n
ordered-by	0..1
reference	0..1
status	0..1
when	0..1
anyxml	0..n
choice	0..n
container	0..n
ct:instance	0..n
ct:instance-list	0..n
leaf	0..n
leaf-list	0..n
list	0..n

Table 3: instance-list's substatements

In case the instance list represents configuration data, the used complex type of an instance MUST have an instance key.

Instances as well as instance lists may appear as arguments of the "deviate" statement.

## 2.5. extends extension statement

A complex type MAY extend exactly one existing base complex type by using the "extends" extension statement. The keyword "extends" MAY occur as substatement of the "complex-type" extension statement. The argument of the "complex-type" extension statement refers to the base complex type via its name. In case a complex type represents configuration data (the default), it MUST have a key, otherwise it MAY have a key. A key is either defined with the key statement as part of the complex type or is inherited from the base complex type.

substatement	cardinality
description	0..1
reference	0..1
status	0..1

Table 4: extends' substatements

## 2.6. abstract extension statement

Complex types may be declared to be abstract by using the "abstract" extension statement. An abstract complex type cannot be instantiated, meaning it cannot appear as most specific type of an instance in NETCONF payload. In case an abstract type extends a base type, the base complex type MUST be also abstract. By default, complex types are not abstract.

The abstract complex type serves only as a base type for derived concrete complex types and cannot be used as a type for an instance in NETCONF payload.

The "abstract" extension statement takes a single string argument, which is either "true" or "false". In case a "complex-type" statement does not contain an "abstract" statement as substatement, the default is "false". The "abstract" statement does not support any substatements.

## 2.7. XML Encoding Rules

An "instance" node is encoded as an XML element, where an "instance-list" node is encoded as a series of XML elements. The XML element name is the "instance" respectively "instance-list" identifier, and its XML namespace is the module's XML namespace.

Instance child nodes are encoded as subelements of the instance XML element. Subelements representing child nodes defined in the same complex type may appear in any order. However child nodes of an extending complex type follow the child nodes of the extended complex type. As such, the XML encoding of lists is similar to the encoding of containers and lists in YANG.

Instance key nodes are encoded as subelements of the instance XML element. Instance key nodes must appear in the same order as they are defined within the "key" statement of the according complex type definition and precede all other nodes defined in the same complex type. I.e. if key nodes are defined in an extending complex type, XML elements representing key data precede all other XML elements representing child nodes. On the other hand XML elements representing key data follow the XML elements representing data nodes of the base type.

The type of actual complex type instance is encoded in a type element, which is put in front of all instance child elements, including key nodes, as described in Section 2.8 ("Type Encoding Rules").

The proposed XML encoding rules conform to the YANG XML encoding rules in [RFC6020]. Compared to YANG, enabling key definitions in derived hierarchies is a new feature introduced with the complex types extension. As a new language feature complex types introduce also a new payload entry for the instance type identifier.

Based on our implementation experience, the proposed XML encoding rules support consistent mapping of YANG models with complex types to XML Schema using XML complex types.

## 2.8. Type Encoding Rules

In order to encode the type of an instance in NETCONF payload, XML elements named "type" belonging to the XML namespace "urn:ietf:params:xml:ns:yang:ietf-complex-type-instance" are added to the serialized form of instance and instance-list nodes in the payload. The suggested namespace prefix is "cti". The "cti:type" XML elements are inserted before the serialized form of all members that have been declared in the according complex type definition.

The "cti:type" element is inserted for each type in the extension chain to the actual type of the instance (most specific last). Each type name includes its corresponding namespace.

The type of a complex type instance MUST be encoded in the reply to NETCONF <get> and <get-config> operations, and in the payload of NETCONF <edit-config> operation if the operation is "create" or "replace". The type of the instance MUST also be specified in case <copy-config> is used to export a configuration to a resource addressed with an URI. The type of the instance has to be specified in user defined RPC's.

The type of the instance MAY be specified in case the operation is "merge" (either because this is explicitly specified or no operation attribute is provided).

In case the node already exists in the target configuration and the type attribute (type of a complex type instance) is specified but differs from the data in the target, an <rpc-error> element is returned with an <error-app-tag> value of "wrong-complex-type". In case no such element is present in the target configuration but the type attribute is missing in the configuration data, an <rpc-error> element is returned with an <error-tag> value of "missing-attribute".

The type MUST NOT be specified in case the operation is "delete".

## 2.9. Extension and Feature Definition Module

The module below contains all YANG extension definitions for complex types and typed instance identifiers. In addition a "complex-type" feature is defined, which may be used to provide conditional or alternative modeling for depending on the support status of complex types in a NETCONF server. A NETCONF server that supports the complex types modeling features and the XML encoding for complex types as defined in this document MUST advertise this as a feature. This is done by including the feature name "complex-types" into the feature parameter list as part of the NETCONF <hello> message as described in Section 5.6.4 in [RFC6020].

#### 2.10. Example Model for Complex Types

The example model below shows how complex types can be used to represent physical equipment in a vendor independent, abstract way. It reuses the complex types defined in the physical resource model in Section 1.5.1

<CODE BEGINS>

```
module hw {

    namespace "http://example.com/hw";
    prefix "hw";

    import ietf-complex-types {prefix "ct"; }
    import udmcore {prefix "uc"; }

    // Holder types

    ct:complex-type Slot {
        ct:extends uc:EquipmentHolder;
        leaf slotNumber { type uint16; config false; }
        // ...
    }

    ct:complex-type Chassis {
        ct:extends uc:EquipmentHolder;
        leaf numberOfChassisSlots { type uint32; config false; }
        // ..
    }

    // Equipment types

    ct:complex-type Card {
        ct:extends uc:Equipment;
        leaf position { type uint32; mandatory true; }
        leaf slotsRequired {type uint32; }
    }

    // Root Element
    ct:instance hardware { type uc:ManagedHardware; }

} // hw module

<CODE ENDS>
```

## 2.11. NETCONF Payload Example

Following example shows the payload of a reply to a NETCONF <get> command. The actual type of managed hardware instances is indicated with the "cti:type" elements as required by the type encoding rules. The containment hierarchy in the NETCONF XML payload reflects the containment hierarchy of hardware instances. This makes filtering

based on the containment hierarchy possible without having to deal with values of key-ref leaves that represent the tree structure in a flattened hierarchy.

```

<hardware>
  <cti:type>uc:BasicObject</cti:type>
  <distinguishedName>/R-T31/CH-2</distinguishedName>
  <globalId>6278279001</globalId>
  <cti:type>uc:Resource</cti:type>
  <cti:type>uc:PhysicalResource</cti:type>
  <otherIdentifier>Rack R322-1</otherIdentifier>
  <serialNumber>R-US-3276279a</serialNumber>
  <cti:type>uc:Hardware</cti:type>
  <cti:type>uc:ManagedHardware</cti:type>
  <cti:type>hw:EquipmentHolder</cti:type>
  <equipmentHolder>
    <cti:type>uc:BasicObject</cti:type>
    <distinguishedName>/R-T31/CH-2/SL-1</distinguishedName>
    <globalId>548872003</globalId>
    <cti:type>uc:Resource</cti:type>
    <cti:type>uc:PhysicalResource</cti:type>
    <otherIdentifier>CU-Slot</otherIdentifier>
    <serialNumber>T-K4733890x45</serialNumber>
    <cti:type>uc:Hardware</cti:type>
    <cti:type>uc:ManagedHardware</cti:type>
    <cti:type>uc:EquipmentHolder</cti:type>
    <equipment>
      <cti:type>uc:BasicObject</cti:type>
      <distinguishedName>/R-T31/CH-2/SL-1/C-3</distinguishedName>
      <globalId>89772001</globalId>
      <cti:type>uc:Resource</cti:type>
      <cti:type>uc:PhysicalResource</cti:type>
      <otherIdentifier>ATM-45252</otherIdentifier>
      <serialNumber>A-778911-b</serialNumber>
      <cti:type>uc:Hardware</cti:type>
      <cti:type>uc:ManagedHardware</cti:type>
      <cti:type>uc:Equipment</cti:type>
      <installed>true</installed>
      <version>A2</version>
      <redundancy>1</redundancy>
      <cti:type>hw:Card</cti:type>
      <usedSlots>1</usedSlots>
    </equipment>
    <cti:type>hw:Slot</cti:type>
    <slotNumber>1</slotNumber>
  </equitmentHolder>
  <cti:type>hw:Chassis</cti:type>
  <numberOfChassisSlots>6</numberOfChassisSlots>
  // ...
</hardware>

```

## 2.12. Update Rules for Modules Using Complex Types

In addition to the module update rules specified in Section 10 in [RFC6020], modules that define complex-types, instances of complex types and typed instance identifiers must obey following rules:

- o New complex types MAY be added.
- o A new complex type MAY extend an existing complex type.
- o New data definition statements MAY be added to a complex type only if:
  - \* they are not mandatory or
  - \* they are not conditionally dependent on a new feature (i.e., have an "if-feature" statement, which refers to a new feature).
- o The type referred to by the instance-type statement may be changed to a type that derives from the original type only if the original type does not represent configuration data.

## 2.13. Using Complex Types

All data nodes defined inside a complex type reside in the complex type namespace, which is their parent node namespace.

### 2.13.1. Overriding Complex Type Data Nodes

It is not allowed to override a data node inherited from a base type. I.e. it is an error if a type "base" with a leaf named "foo" is extended by another complex type ("derived") with a leaf named "foo" in the same module. In case they are derived in different modules, there are two distinct "foo" nodes which are mapped to the XML namespaces of the module, where the complex types are specified.

A complex type that extends a basic complex type may use the "refine" statement in order to improve an inherited data node. The target node identifier must be qualified by the module prefix to indicate clearly, which inherited node is refined.

The following refinements can be done:

- o A leaf or choice node may have a default value, or a new default value if it already had one
- o Any node may have a different "description" or "reference" string.

- o A leaf, anyxml, or choice node may have a "mandatory true" statement. However, it is not allowed to change from "mandatory true" to "mandatory false".
- o A leaf, leaf-list, list, container, or anyxml node may have additional "must" expressions.
- o A list, leaf-list, instance or instance-list node may have a "min-elements" statement, if the base type does not have one or one with a value that is greater than the minimum value of the base type.
- o A list, leaf-list, instance or instance-list node may have a "max-elements" statement, if the base type does not have one or one with a value that is smaller than the maximum value of the base type.

It is not allowed to refine complex-type nodes inside instance or instance-list statements.

#### 2.13.2. Augmenting Complex Types

Augmenting complex types is only allowed if a complex type is instantiated in an "instance" or "instance-list" statement. This confines the effect of the augmentation to the location in the schema tree, where the augmentation is done. The argument of the "augment" statement MUST be in the descendant form (as defined by the rule "descendant-schema-nodeid" in Section 12 in [RFC6020]).

```
ct:complex-type Chassis {
    ct:extends EquipmentHolder;
    container chassisInfo {
        config false;
        leaf numberOfSlots { type uint16; }
        leaf occupiedSlots { type uint16; }
        leaf height {type unit16;}
        leaf width {type unit16;}
    }
}

ct:instance-list chassis {
    type Chassis;
    augment "chassisInfo" {
        leaf modelId { type string; }
    }
}
```

When augmenting a complex type, only the "container", "leaf", "list", "leaf-list", "choice", "instance", "instance-list" and "if-feature" statements may be used within the "augment" statement. The nodes added by the augmentation MUST NOT be mandatory nodes. One or many augment statements may not cause the creation of multiple nodes with the same name from the same namespace in the target node.

To achieve less complex modeling this document proposes the augmentation of complex type instances without recursion.

### 2.13.3. Controlling the Use of Complex Types

A server might not want to support all complex types defined in a supported module. This issue can be addressed with YANG features as follows:

- o Features are defined that are used inside complex type definitions (by using "if-feature" as substatement) to make them optional. In this case such complex types may only be instantiated if the feature is supported (advertized as capability in the NETCONF <hello> message).
- o The "deviation" statement may be applied to node trees, which are created by "instance" and "instance-list" statements. In this case, only the substatement "deviate not-supported" is allowed.
- o It is not allowed to apply the deviation statement to node tree elements that may occur because of the recursive use of a complex type. Other forms of deviations ("deviate add", "deviate replace", "deviate delete") are NOT supported inside node trees spanned by "instance" or "instance-list".

As complex type definitions do not contribute by itself to the data node tree, data node declarations inside complex types cannot be target of deviations.

In the example below, client applications are informed that the leaf "occupiedSlots" is not supported in the top-level chassis. However, if a chassis contains another chassis, the contained chassis may support the leaf informing about the number of occupied slots.

```
deviation "/chassis/chassisSpec/occupiedSlots" {  
    deviate not-supported;  
}
```

### 3. Typed Instance Identifier

#### 3.1. Definition

Typed instance identifier relationships are an addition to the relationship types already defined in YANG, where the leafref relationship is location dependent, and the instance-identifier does not specify to which type of instances the identifier points to.

A typed instance identifier represents a reference to an instance of a complex type without being restricted to a particular location in the containment tree. This is done by using the extension statement "instance-type" as a substatement of the existing "type instance identifier" statement.

Typed instance identifiers allow referring to instances of complex types that may be located anywhere in the schema tree. The "type" statement plays the role of a restriction that must be fulfilled by the target node, which is referred to with the instance identifier. The target node **MUST** be of a particular complex type, either the type itself or any type that extends this complex type.

#### 3.2. instance-type extension statement

The "instance-type" extension statement specifies the complex type of the instance referred by the instance-identifier. The referred instance may also instantiate any complex type that extends the specified complex type.

The instance complex type is identified by the single name argument. The referred complex type **MUST** have a key. This extension statement **MUST** be used as a substatement of the "type instance-identifier" statement. The "instance-type" extension statement does not support any substatements.

#### 3.3. Typed Instance Identifier Example

In the example below, a physical link connects an arbitrary number of physical ports. Here typed instance identifiers are used to denote, which "PhysicalPort" instances (anywhere in the data tree) are connected by a "PhysicalLink".

```

// Extended version of type Card
ct:complex-type Card {
  ct:extends Equipment;
  leaf usedSlot { type uint16; mandatory true; }
  ct:instance-list port {
    type PhysicalPort;
  }
}

ct:complex-type PhysicalPort {
  ct:extends ManagedHardware;
  leaf portNumber { type int32; mandatory true; }
}

ct:complex-type PhysicalLink {
  ct:extends ManagedHardware;
  leaf media { type string; }
  leaf-list connectedPort {
    type instance-identifier {
      ct:instance-type PhysicalPort;
    }
    min-elements 2;
  }
}

```

Below is the XML encoding of an element named "link" of type "PhysicalLink":

```

<link>
  <objectId>FTCL-771</objectId>
  <media>Fiber</media>
  <connectedPort>/hw:hardware[objectId='R-11']
    /hw:equipment[objectId='AT22']/hw:port[objectId='P12']
  </connectedPort>
  <connectedPort>/hw:hardware[objectId='R-42']
    /hw:equipment[objectId='AT30']/hw:port[objectId='P3']
  </connectedPort>
  <serialNumeber>F-7786828</serialNumber>
  <commonName>FibCon 7</commonName>
</link>

```

#### 4. IANA Considerations

This document registers two URIs in the IETF XML registry. Following the format in [RFC3688], the following registrations are requested:

URI: urn:ietf:params:xml:ns:yang:ietf-complex-types  
URI: urn:ietf:params:xml:ns:yang:ietf-complex-type-instance

Registrant Contact: The NETMOD WG of the IETF.

XML: N/A, the requested URIs are XML namespaces.

This document registers one module name in the 'YANG Module Names' registry, defined in [RFC6020].

name: ietf-complex-types

namespace: urn:ietf:params:xml:ns:yang:ietf-complex-types

prefix: ct

RFC: XXXX

RFC Ed.: Please replace XXXX with actual RFC number and remove this note.

## 5. Security Considerations

The YANG module "complex-types" in this memo defines YANG extensions for Complex-types and Typed Instance Identifiers as new language statements.

Complex-types and Typed Instance Identifiers themselves do not have any security impact on the Internet.

The security considerations described throughout [RFC6020] apply here as well.

## 6. Acknowledgements

The authors would like to thank to Martin Bjorklund, Balazs Lengyel, Gerhard Muenz, Dan Romascanu, Juergen Schoenwaelder and Martin Storch for their valuable review and comments on different versions of the document.

## Appendix A. Change Log

### A.1. 03-04

- o Changed the complex type XML encoding rules so that XML elements representing data nodes defined in the same complex type may appear in any order.
- o Used the "ct:" prefix in substatement tables when referring to complex type extension statements.

- o Modeled the IPFIX/PSMAP example based on v-07 of the IPFIX configuration draft. Changed motivation text accordingly.
- o Minor updates and clarifications in the text.

#### A.2. 02-03

- o Added an example based on the physical resource modeling concepts of SID. A simplified class diagram and an excerpt of an according YANG module were added in the introduction section.
- o Changed the example YANG module in the NETCONF payload section to be based on the physical resource types defined in the added physical resource model.
- o A second example shows how Entity MIB entries can be modeled as physical resources. The example includes a class diagram and an according YANG module excerpt.
- o The complete YANG modules for both examples were added into the appendix.
- o Changed the complex type encoding rules.
- o Updated the NETCONF payload example the changed type encoding rules and the changed example module.
- o Changed the augmentation rules for complex types. Instead of using "." as argument in the augment statement, instance and instance-list statement may now contain additional data node statements. The substatement tables for the instance and instance-list statements were updated accordingly.
- o Minor updates in the text and examples.

#### A.3. 01-02

- o It is no longer allowed to use the "config" statement inside a complex type definition.
- o Complex type can now be defined where a grouping can be defined. Complex types have their own namespace.
- o Explicitly specified which kind of refinements can be applied to elements of the base type in the definition of an extending complex type.

- o Confined the use of deviations for complex types to complex type instantiations.
- o Defined augmentation of complex types allowing augmentation only during instantiation via an "instance" or "instance-list" statement.
- o Removed leftovers from substatement tables.
- o Updates and bug-fixes in the examples.

#### A.4. 00-01

- o Transformed proposed new YANG statements to YANG extension statements (complex-type, element, extends, abstract).
- o Renamed statement "element" to the extension statement "instance" in order to avoid confusion with XML payload elements.
- o Introduced extension statement "instance-type" as allowing the use of the existing "type" statement as substatement in the existing "instance-identifier" statement cannot be done with extensions.
- o Added the complex type extension statement module.
- o Updated examples to reflect the changes mentioned above.
- o Added update rules for complex types.
- o Updated IANA Considerations section.
- o Added this change log.

#### Appendix B. YANG Modules for Physical Network Resource Model and Hardware Entities Model

YANG module for the 'Physical Network Resource Model':

<CODE BEGINS>

```
module udmcore {  
  
    namespace "http://example.com/udmcore";  
    prefix "udm";  
  
    import ietf-yang-types {prefix "yang";}   
    import ietf-complex-types {prefix "ct";}   
}
```

```
ct:complex-type BasicObject {
  ct:abstract true;
  key "distinguishedName";
  leaf globalId {type int64;}
  leaf distinguishedName {type string; mandatory true;}
}

ct:complex-type ManagedObject {
  ct:extends BasicObject;
  ct:abstract true;
  leaf instance {type string;}
  leaf objectState {type int32;}
  leaf release {type string;}
}

ct:complex-type Resource {
  ct:extends ManagedObject;
  ct:abstract true;
  leaf usageState {type int16;}
  leaf managementMethodSupported {type string;}
  leaf managementMethodCurrent {type string;}
  leaf managementInfo {type string;}
  leaf managementDomain {type string;}
  leaf version {type string;}
  leaf entityIdentification {type string;}
  leaf description {type string;}
  leaf rootEntityType {type string;}
}

ct:complex-type LogicalResource {
  ct:extends Resource;
  ct:abstract true;
  leaf lrStatus {type int32;}
  leaf serviceState {type int32;}
  leaf isOperational {type boolean;}
}

ct:complex-type PhysicalResource {
  ct:extends Resource;
  ct:abstract true;
  leaf manufactureDate {type string;}
  leaf otherIdentifier {type string;}
  leaf powerState {type int32;}
  leaf serialNumber {type string;}
  leaf versionNumber {type string;}
```

```
}

ct:complex-type Hardware {
  ct:extends PhysicalResource;
  ct:abstract true;
  leaf width {type string;}
  leaf height {type string;}
  leaf depth {type string;}
  leaf measurementUnits {type int32;}
  leaf weight {type string;}
  leaf weightUnits {type int32;}
  leaf-list physicalLink {
    type instance-identifier {
      ct:instance-type PhysicalLink;
    }
  }
  ct:instance-list containedHardware {
    ct:instance-type Hardware;
  }
  ct:instance-list physicalConnector {
    ct:instance-type PhysicalConnector;
  }
}

ct:complex-type PhysicalLink {
  ct:extends PhysicalResource;
  leaf isWireless {type boolean;}
  leaf currentLength {type string;}
  leaf maximumLength {type string;}
  leaf mediaType {type int32;}
  leaf-list hardware {
    type instance-identifier {
      ct:instance-type Hardware;
    }
  }
}

ct:complex-type ManagedHardware {
  ct:extends Hardware;
  leaf additionalInfo {type string;}
  leaf physicalAlarmReportingEnabled {type boolean;}
  leaf physicalAlarmStatus {type int32;}
  leaf coolingRequirements {type string;}
  leaf hardwarePurpose {type string;}
  leaf isPhysicalContainer {type boolean;}
```

```
    }

    ct:complex-type AuxiliaryComponent {
        ct:extends ManagedHardware;
        ct:abstract true;
    }

    ct:complex-type PhysicalPort {
        ct:extends ManagedHardware;
        leaf portNumber {type int32;}
        leaf duplexMode {type int32;}
        leaf ifType {type int32;}
        leaf vendorPortName {type string;}
    }

    ct:complex-type PhysicalConnector {
        ct:extends Hardware;
        leaf location {type string;}
        leaf cableType {type int32;}
        leaf gender {type int32;}
        leaf inUse {type boolean;}
        leaf pinDescription {type string;}
        leaf typeOfConnector {type int32;}
        leaf-list sourcePhysicalConnector {
            type instance-identifier {
                ct:instance-type PhysicalConnector;
            }
        }
        leaf-list targetPhysicalConnector {
            type instance-identifier {

## Appendix C. Example YANG Module for the IPFIX/PSAMP Model

### C.1. Modeling Improvements for the IPFIX/PSAMP Model with Complex types and Typed instance identifiers

The module below is a variation of the IPFIX/PSAMP configuration model, which uses complex types and typed instance identifiers to model the concept outlined in [IPFIXCONF].

When looking at the YANG module with complex types and typed instance identifiers, various technical improvements on modeling level become apparent.

- o There is almost a one-to-one mapping between the domain concepts introduced in IPFIX and the complex types in the YANG module
- o All associations between the concepts (which are not containment) are represented with typed identifiers. That avoids having to refer to a particular location in the tree, which is not mandated by the original model.
- o It is superfluous to represent concept refinement (class inheritance in the original model) with containment in form of quite big choice-statements with complex branches. Instead, concept refinement is realized by complex types extending a base complex type.
- o It is unnecessary to introduce metadata identities and leafs (e.g. "identity cacheMode" and "leaf cacheMode" in "grouping cacheParameters") that just serve the purpose of indicating which concrete sub-type of a generic type (modeled as grouping, which contains the union of all features of all subtypes) is actually represented in the MIB.

- o Ruling out illegal use of sub-type specific properties (e.g. "leaf maxFlows") by using "when" statements that refer to a sub-type discriminator is not necessary (e.g. when "../cacheMode != 'immediate'").
- o It is not needed to define properties like the configuration status wherever a so called "parameter grouping" is used. Instead those definitions can be put inside the complex-type definition itself.
- o It can be avoided to separating the declaration of the key from the related data nodes definitions in a grouping (see use of "grouping selectorParameters").
- o Complex types may be declared as optional features. If the type is indicated with an identity (e.g. "identity immediate"), this is not possible, since "if-feature" is not allowed as a substatement of "identity".
