Providing interactive service for multicast sessions

- **Conventional multicast session serves multiple users**
- **When a user wants to use interactive service (e.g. pause, rewind...) typically a unicast session is created for this user.**

The problem to address

- **When many users use interactive services at the same time multiple unicast sessions are established using more bandwidth. The worse case is all users keeping unicast connections.**
- **The objective will be to resume the connection to the multicast session as soon as possible.**

Proposed solution

- **For short time-shift case can slightly speeding up the unicast playback until it catch up to the primary multicast stream.**
- **This has an added user advantage that there is no loss of video information.**
- **Short time-shift duration is limited by the playback speed.**

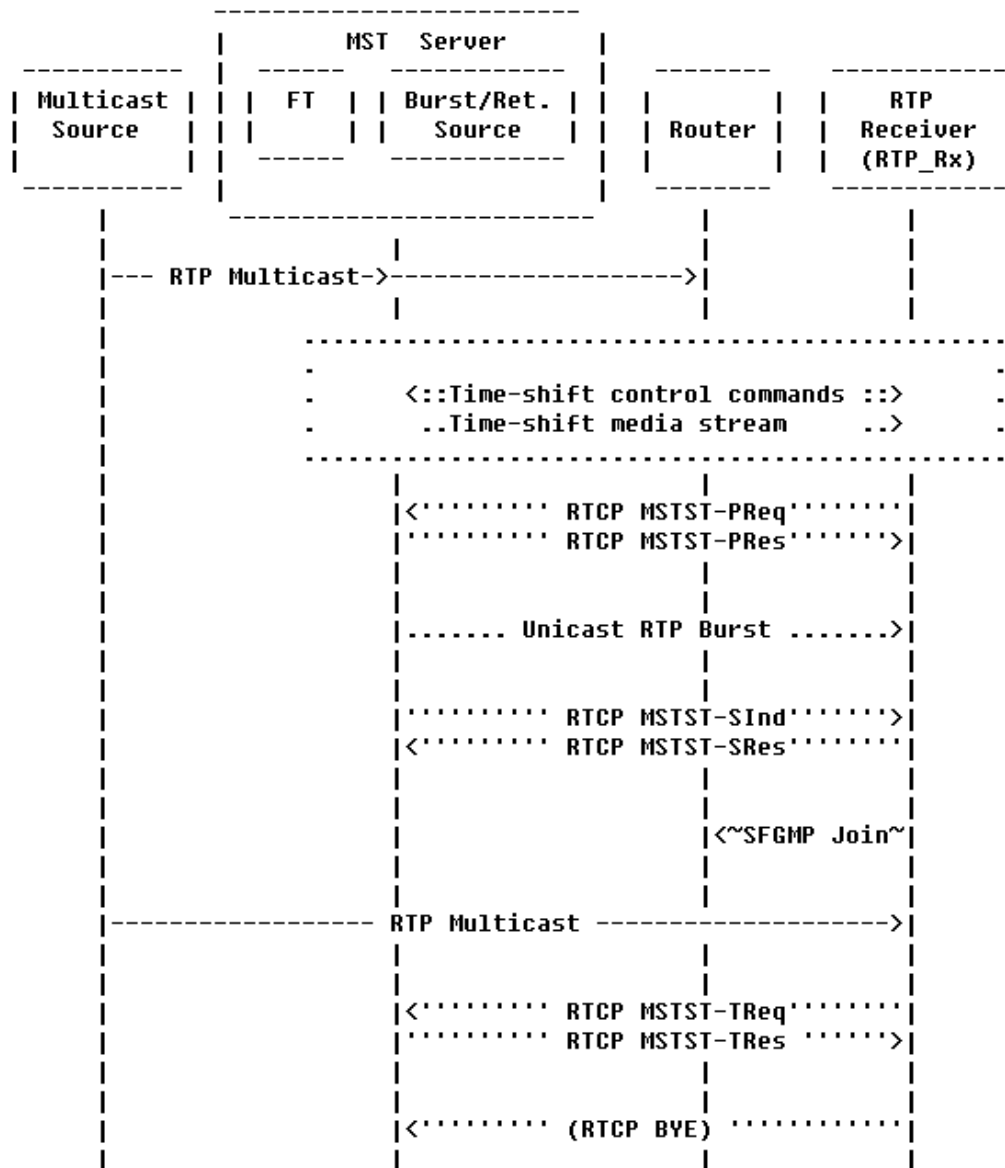

RTSP time-shift

- **RTSP can provide interactive time-shift function with different scale and speed, and an initial switch from multicast session to unicast session**
- **RTSP does not provide a way to switch back from unicast session of time-shift to the original multicast session**

Multicast short time-shift based on RTCP

- **The proposed solution using RTCP feedback will be independent of a specific streaming control protocol like RTSP.**
- **It addresses the synchronization between a primary multicast RTP stream and a parallel time-shifted unicast RTP stream.**

The procedure of MST

Advantage of the proposal

- **Switching back to the multicast session from the unicast session of time-shift, and effectively saving bandwidth.**
- **Adding user advantage that there is no loss of video information.**

Thank you
