Path Computation Element (PCE) Protocol Extension for Stateful PCE
Usage in GMPLS Networks

draft-zhang-pce-pcep-stateful-pce-gmpls-02.txt

Status of this Memo

This Internet-Draft is submitted to IETF in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/lid-abstracts.txt>.

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>.

This Internet-Draft will expire on August 21, 2013.

Abstract

The Path Computation Element (PCE) facilitates Traffic Engineering (TE) based path calculation in large, multi-domain, multi-region, or multi-layer networks. [Stateful-PCE] provides the fundamental PCEP extensions needed to support stateful PCE functions, without specifying the technology-specific extensions. This memo provides extensions required for PCE communication protocol (PCEP) so as to enable the usage of a stateful PCE capability in GMPLS networks.

1. Introduction

[RFC 4655] presents the architecture of a Path Computation Element (PCE)-based model for computing Multiprotocol Label Switching (MPLS) and Generalized MPLS (GMPLS) Traffic Engineering Label Switched Paths (TE LSPs). To perform such a constrained computation, a PCE stores the network topology (i.e., TE links and nodes) and resource information (i.e., TE attributes) in its TE Database (TED). To request path computation services to a PCE, [RFC 5440] defines the PCE Communication Protocol (PCEP) for communications between a Path Computation Client (PCC) and a PCE, or between two PCEs. PCEP protocol specified in [RFC 5440] mainly focuses on MPLS networks and the PCEP extensions needed for GMPLS-controlled networks are provided in [PCEP-GMPLS].

Stateful PCEs are shown to be helpful in many application scenarios, in both MPLS and GMPLS networks, as illustrated in [Stateful-APP]. In order for these applications to be able to exploit the capability of stateful PCEs, extensions to the PCE communication protocol (i.e., PCEP) are required.

[Stateful-PCE] provides the fundamental extensions needed for stateful PCE to support general functionality, but leaves out the specification for technology-specific objects/TLVs. Complementarily, this document focuses on the extensions that are necessary in order for its deployment in GMPLS-controlled networks.

2. PCEP Extensions

2.1. Overview of Requirements

This section notes the main functional requirements for PCEP extensions to support stateful PCE for use in GMPLS networks, based on the description in [Stateful-APP]. Many requirements are common across a variety of network types (e.g., MPLS-TE networks and GMPLS networks) and the protocol extensions to meet the requirements are already described in [Stateful-PCE]. This document does not repeat the description of those protocol extensions. Other requirements that are also common across a variety of network types do not currently have protocol extensions defined in [Stateful-PCE]. In these cases, this document presents protocol extensions for discussion by the PCE working group and potential inclusion in [Stateful-PCE]. In addition, this document presents protocol extensions for a set of requirements which are specific to the use of a stateful PCE in a GMPLS-controlled network.

The basic requirements are as follows:

- o Advertisement and negotiation of the stateful PCE capability. This generic requirement is covered in Section 7.1.1 of [Stateful-PCE]. Section 2.2 of this document discusses other potential extensions for this functionality.
- o LSP delegation is already covered in Section 5.5 of [Stateful-PCE]. Section 2.3 of this document provides extension for its application in GMPLS-controlled networks. Moreover, further discussion of some generic details that may need additional consideration is provided.
- o LSP synchronization (see [Stateful-APP] Section 2.2). This is a generic requirement already covered in Section 5.4 of [Stateful-PCE]. However, there are further extensions required specifically for GMPLS networks and discussed in Section 2.4.o Reference to LSPs by identifiers is discussed in Section 7.2 of [Stateful-PCE]. This feature can be applied to reduce the data carried in PCEP messages. Use cases and additional Error Codes are necessary, as described in Section 2.5 and 2.6.

2.2. Stateful PCE Capability Advertisement and Negotiation

Whether a PCE has stateful capability or not can be negotiated during the PCEP session establishment process. It can also be advertised through routing protocols as described in [RFC5088]. In either case, the following additional aspects should also be considered.

2.2.1. PCE Capability Negotiation/Advertisement in Multi-layer Networks

In multi-layer network scenarios, such as an IP-over-optical network, if there are dedicated PCEs responsible for each layer, then the PCCs should be informed of which PCEs they should synchronize their LSP states with, as well as send path computation requests to. The Layer-Cap TLV defined in [INTER-LAYER] can be used to indicate which layer a PCE is in charge of. This TLV is optional and MAY be carried in the OPEN object. It is RECOMMENDED that a PCC synchronizes its LSP states with the same PCEs that it can use for path computation in a multi-layer network. In a single layer, this TLV MAY not be used. However, if the PCE capability discovery depends on IGP and if an IGP instance spans across multiple layers, this TLV is still needed.

Alternatively, the extension to current OSPF PCED TLV is needed. A new domain-type denoting the layer information can be defined:

domain-type: T.B.D.

When it is carried in PCE-DOMAIN sub-TLV, it denotes the layer for which a PCE is responsible for path computation as well as LSP state synchronization. When carried in the PCE-NEIG-DOMAIN sub-TLV, it denotes its adjacent layers for which a PCE can compute paths and synchronize the LSP states. The DOMAIN-ID information can be represented using the following format, to denote the layer information:

0										1										2										3									
0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+																																							
LSP Enc. Type										Switching Type										Reserved																			
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+																																							

2.3. LSP Delegation in GMPLS Networks

To enable the PCE to control an LSP, the PCUpd message is defined in [Stateful-PCE]. However, technology-specific specification is not covered. The following defines the <path> descriptor that should be used in GMPLS networks:

<path> ::= <ERO> <attribute-list>

Where:

```

<attribute-list> ::= [ <LSPA> ]
                    [ <BANDWIDTH> ]
                    [ <GENERALIZED-BANDWIDTH>... ]
                    [ <metric-list> ]

<metric-list> ::= <METRIC> [ <metric-list> ]

```

The 0 bit in the <GENERALIZED-BANDWIDTH> object has no meaning for LSP state synchronization and MUST be set to 0. Furthermore, this object MAY appear twice, one with R set to 1 and the other with R set to 0. This is to denote the asymmetric bandwidth property of the updated bi-directional LSP.

As explained in [stateful-APP], LSP state synchronization and/or LSP parameter change controlled by a stateful PCE in a multi-domain network is complex and requires well-defined operational procedures as well as protocol design.

[TBD: protocol extensions]

2.4. LSP Synchronization in GMPLS networks

For LSP state synchronization of stateful PCEs in GMPLS networks, the LSP attributes, such as its bandwidth, associated route as well as protection information etc, should be updated by PCCs to PCE LSP database (LSP-DB). Note the LSP state synchronization described in this document denotes both the bulk LSP report at the initialization phase as well as the LSP state report afterwards described in [Stateful-PCE].

As per [Stateful-PCE], it does not cover technology-specific specification for state synchronization. Therefore, extensions of PCEP protocol for stateful PCE usage in GMPLS networks are required. For LSP state synchronization, the objects/TLVs that should be used for stateful PCE in GMPLS networks are defined in [PCEP-GMPLS] and are briefly summarized as below:

- o GENERALIZED BANDWIDTH
- o GENERALIZED ENDPOINTS
- o PROTECTION ATTRIBUTE
- o Use of IF_ID_ERROR_SPEC. [Stateful-PCE] section 7.2.2 only considers RSVP_ERROR_SPEC TLVs. GMPLS extends this to also support IF_ID_ERROR_SPEC, for example, to report about failed unnumbered interfaces.
- o Extended Objects to support the inclusion of the label and unnumbered links.

Per [Stateful-PCE], the PCRpt message is defined for LSP state synchronization purpose. PCRpt is used by a PCC to report one or more of its LSPs to a stateful PCE. However, the <path> descriptor is technology-specific and left undefined.

For LSP state synchronization in GMPLS networks, the encoding of the <path> descriptor is defined as follows:

```
<path> ::= <ERO> <attribute-list>
```

Where:

```
<attribute-list> ::= [ <LSPA> ]
                        [ <BANDWIDTH> ]
```

[<GENERALIZED-BANDWIDTH>...]

[<RRO>]

[<IRO>]

[<XRO>]

[<metric-list>]

<metric-list>::= <METRIC>[<metric-list>]

The objects included in the <path> descriptor can be found in [RFC5440], [PCE-GMPLS] and [RFC5521].

For all the objects presented in this section, the P and I bit MUST be set to 0 since they are only used by a PCC to report its LSP information.

In GMPLS networks, the <ERO> object may include a list of the label sub-object for SDH/SONET, OTN and DWDM networks. It may also include a list of unnumbered interface IDs to denote the allocated resource. The <RRO>, <IRO> and <XRO> objects MAY include unnumbered interface IDs and labels for networks such as OTN and WDM networks.

If the LSP being reported is a protecting LSP, the <PROTECTION-ATTRIBUTE> TLV MUST be included in the <LSPA> object to denote its attributes and restrictions. Moreover, if the status of the protecting LSP changes from non-operational to operational, this should be synchronized to the stateful PCE. For example, in 1:1 protection, the combination of S=0, P=1 and O=0 denotes the protecting path is set up already but not used for carrying traffic. Upon the working path failure, the operational status of the aforementioned protecting LSP changes to in-use (i.e., O=1). This information should be synchronized with a stateful PCE through a PCRpt message.

The O bit in the <GENERALIZED-BANDWIDTH> object has no meaning for LSP state synchronization and MUST be set to 0. Furthermore, this object MAY appear twice, one with R set to 1 and the other with R set to 0. This is to denote the asymmetric bandwidth property of the updated bi-directional LSP.

2.5. Modification of Existing PCEP Messages and Procedures

One of the advantages mentioned in [Stateful-APP] is that the stateful nature of a PCE simplifies the information conveyed in PCEP messages, notably between PCC and PCE, since it is possible to refer to PCE managed state for active LSPs. To be more specific, with a stateful PCE, it is possible to refer to a LSP with a unique identifier in the scope of the PCC-PCEP session and thus use such identifier to refer to that LSP.

2.5.1. Use cases

Use Case 1: Assuming a stateful PCE's LSP-DB is up-to-date, a PCC (e.g. NMS) requesting for a re-optimization of one or several LSPs can send the request with 'R' bit set and only provides the relevant LSP unique identifiers.

Upon receiving the PCReq message, PCE should be able to correlate with one or multiple LSPs with their detailed state information and carry out optimization accordingly.

The handling of RP object specified in [RFC5440] is stated as following:

'The absence of an RRO in the PCReq message for a non-zero-bandwidth TE LSP (when the R bit of the RP object is set) MUST trigger the sending of a PCErr message with Error-Type="Required Object Missing" and Error-value="RRO Object missing for re-optimization."

If a PCE has stateful capabilities, and such capabilities have been negotiated and advertised, specific rules given in [RFC5440] may need to be relaxed. In particular, the re-optimization case: if the re-optimization request refers to a given LSP state, and the RRO information is available, the PCE can proceed.

Use Case 2: in order to set up a LSP which has a constraint that its route should not use resources used by one or more existing LSPs, a PCC can send a PCReq with the identifiers of these LSPs. A stateful PCE should be able to find the corresponding route and resource information so as to meet the constraints set by the requesting PCC. Hence, the LSP identifier TLV defined in [Stateful-PCE] can be used in XRO object for this purpose. Note that if the PCC is a node in the network, the constraint LSP ID information will be confined to the LSPs initiated by itself.

2.5.2. Modification for LSP Re-optimization

For re-optimization, upon receiving a path computation request and the 'R' bit is set, the stateful PCE SHOULD still perform the re-optimization in the following two cases:

Case 1: the existing bandwidth and route information of the to-be-optimized LSP is provided in the path computation request. This information should be provided via <BANDWIDTH>, <GENERALIZED-BANDWIDTH>, <ERO> objects.

Case 2: the existing bandwidth and route information can be found locally in its LSP-DB. In this case, the PCRep and PCReq messages need to be modified to carry LSP identifiers. The stateful PCE can find this information using the per-node LSP ID together with the PCC's address.

If no LSP state information is available to carry out re-optimization, the stateful PCE should report the error 'LSP state information unavailable for the LSP re-optimization' (Error Type = T.B.D., Error value= T.B.D.).

2.5.3. Modification for Route Exclusion

A LSP identifier sub-object is defined and its format as follows:

L bit:

The L bit SHOULD NOT be set, so that the subobject represents a strict hop in the explicit route.

Type:

Subobject Type for a per-node LSP identifier.

Length:

The Length contains the total length of the subobject in bytes, including the Type and Length fields.

LSP ID:

This is the identifier given to a LSP and it is unique on a node basis. It is defined in [Stateful-PCE].

Flags:

This field is defined in [Stateful-PCE]. It is not used in this sub-object and should be ignored upon receipt.

Optional TLVs:

Additional TLVs can be defined in the future to provide further information to identify a LSP. In this document, no TLVs are defined.

One or multiple of these sub-objects can be present in the XRO object. When a stateful PCE receives a path computation request carrying this sub-object, it should find relevant information of these LSPs and preclude the resource during the path computation process. If a stateful PCE cannot recognize one or more of the received LSP identifiers, it should reply PCErr saying "the LSP state information for route exclusion purpose cannot be found" (Error-type = T.B.D., Error-value= T.B.D.). Optionally, it may provide with the unrecognized identifier information to the requesting PCC.

2.6. Additional Error Type and Error Values Defined

Error Type Meaning

21(TBD) LSP state information missing

 Error-value 1: LSP state information unavailable for the LSP re-optimization

3. Error-value 2: the LSP state information for route exclusion purpose cannot be found IANA Considerations

IANA is requested to allocate new Types for the TLV/Object defined in this document.

T.B.D.

4. Manageability Considerations

The description and functionality specifications presented related to stateful PCEs should also comply with the manageability specifications covered in Section 8 of [RFC4655]. Furthermore, a further list of manageability issues presented in [Stateful-PCE] should also be considered.

Additional considerations are presented in the next sections.

4.1. Requirements on Other Protocols and Functional Components

When the detailed route information is included for LSP state synchronization (either at the initial stage or during LSP state report process), this require the ingress node of an LSP carry the RRO object in order to enable the collection of such information.

5. Security Considerations

The security issues presented in [RFC5440] and [Stateful-PCE] apply to this document.

6. Acknowledgement

We would like to thank Adrian Farrel and Cyril Margaria for the useful comments and discussions.
