Requirements

- Network performance criteria are becoming critical to path selection
- For example,
 - A financial customer wants a path that meets a certain delay;
 - The service provider is interested in the minimum cost path that meets that requirement.
- Extensions to the PCEP have already been made to express
 - objective functions [RFC5541]
 - metric bound [draft-ietf-pce-pcep-service-aware].

Overall Problem Space

- A TE headend may have no visibility across UNI or NNI boundaries.
- TE headend may not have access to a PCE fully capable of performing the calculations.
- The UNI-N or (and) NNI node(s) is (are) fully capable of performing the calculations and thus no PCE has been deployed.

Expressing the Metric Bound

A new ERO subobject type, Metric Bound (MB) is defined

- Carries the bound on some path metric that needs to be respected for the strict or the loose segment
 - Metric Bound in strict hop is used to aid selection of an appropriate component link within a bundled TE link
- A “best-effort” bit is supported
- Multiple MB subobjects may be present and all are processed
 - Note that doing so may lead to an overly constrained problem
- A loose hop expansion may result in the insertion of a new loose hop(s)
 - Determining the metric bound for the inserted loose hops is local to the node adding the loose hops

Changes from -02

- Added Daniele Ceccarelli as a new co-author.
- Addressed/discussed comments received on the draft
 - Added best-effort bit in Metric Bound subobject
 - If expanding node is doing CSPF, first pass will prune paths that exceed MB
 - If no path found, then rerun CSPF but don't prune on that metric
 - Simply a short cut to avoid some ressignaling
 - Removed optional TLVs from the Objective Function subobject
 - One open discussion on a Path MB
- Some text improvements.

Next Steps

- Authors consider draft mature enough to call for WG adoption
