Table of contents

- 1 Context and objectives
- 2 Metrics
 - Queue-related metrics
 - End-to-end metrics
- 3 Evaluation scenarios
 - Methodology
 - Topology
 - Generic scenarios
 - Diverse network environments
- 4 Deployment
 - Operator control knobs and auto-tuning
 - Parameter sensitivity and stability analysis
 - Implementation cost
 - Interaction with packet scheduling
 - ECN behavior
 - Packet sizes and congestion notification
- 5 Comparing AQMs

Context

- Active Queue Management (AQM) addresses the concerns arising from using unnecessarily large and unmanaged buffers
- AQM : one of the solutions to the bufferbloat issues (and reduce end-to-end latency)
- how do we get the confidence that a specific AQM is better than drop tail and thus "safe" to deploy?
- the WG requires guidelines to ascertain whether the WG should undertake an AQM proposal

Objectives

- define operating regions of an AQM proposal and discuss the parameters sensitivity
- evaluation guidelines for very diverse network environments
- **guidelines for performance evaluation** :
 - how does the proposal compare drop-tail :
 - trade off between reducing the latency and maximizing the goodput
- **guidelines for safe deployment** :
 - how safe is it to deploy the proposal compared to the issues encountered by RED

Table of contents

- 1 Context and objectives
- 2 **Metrics**
 - Queue-related metrics
 - End-to-end metrics
- 3 Evaluation scenarios
 - Methodology
 - Topology
 - Generic scenarios
 - Diverse network environments
- 4 Deployment
 - Operator control knobs and auto-tuning
 - Parameter sensitivity and stability analysis
 - Implementation cost
 - Interaction with packet scheduling
 - ECN behavior
 - Packet sizes and congestion notification
- 5 Comparing AQMs

Metrics to evaluate the trade-off between latency and goodput

- provide generic metrics that can be exploited to evaluate the performance of an AQM, whatever the context
- propose set of metrics to effectively evaluate the trade-off between latency and goodput
- an AQM proposal should :
 - control latency at a desired level
 - minimize the hit on goodput

Queue-related metrics

- Why queue-related metrics?
 - queue-related metrics MUST be considered to understand the behavior of an AQM and the possible impact of its internal parameters
- Which queue-related metrics?
 - **link utilization** : [RFC5136] “the utilization now represents the fraction of the capacity that is being used and is a value between zero (meaning nothing is used) and one (meaning the link is fully saturated)”
 - **queuing delay and queue size** : The queuing delay is the time a packet waits in a queue until it can be forwarded to the lower layers. The queue size is the number of bytes which are occupying the queue.
 - two classes of **packet loss** : AQM-induced losses and buffer overflow
 - long-term packet loss probability
 - time interval between consecutive losses
 - any other queue-related metrics for performance evaluation?

End-to-end metrics

- **Why end-to-end metrics?**
 - End-to-end metrics **MUST** be considered to evaluate the consequences of introducing an AQM on the latency and the goodput
- **Which end-to-end metrics?**
 - **flow completion time** : distribution of the flow completion time depending on the flow size
 - **packet loss** : long term packet loss probability, loss inter-arrival time and packet loss pattern
 - **packet loss synchronization** : degree of synchronization of loss events between two flows on the same path
 - **goodput** : important if scheduling comes into play (possible flow starvation) - end-to-end assessment of how well the AQM improves transport application performance
 - **latency and jitter** : differs from queuing delay and depends on traffic and topology
 - **QoE** : metrics to assess AQM's performance for dedicated context (VoIP, video-streaming, data centers, web)
 - **any other end-to-end metrics for performance evaluation?**

Table of contents

- 1 Context and objectives
- 2 Metrics
 - Queue-related metrics
 - End-to-end metrics
- 3 Evaluation scenarios**
 - Methodology
 - Topology
 - Generic scenarios
 - Diverse network environments
- 4 Deployment
 - Operator control knobs and auto-tuning
 - Parameter sensitivity and stability analysis
 - Implementation cost
 - Interaction with packet scheduling
 - ECN behavior
 - Packet sizes and congestion notification
- 5 Comparing AQMs

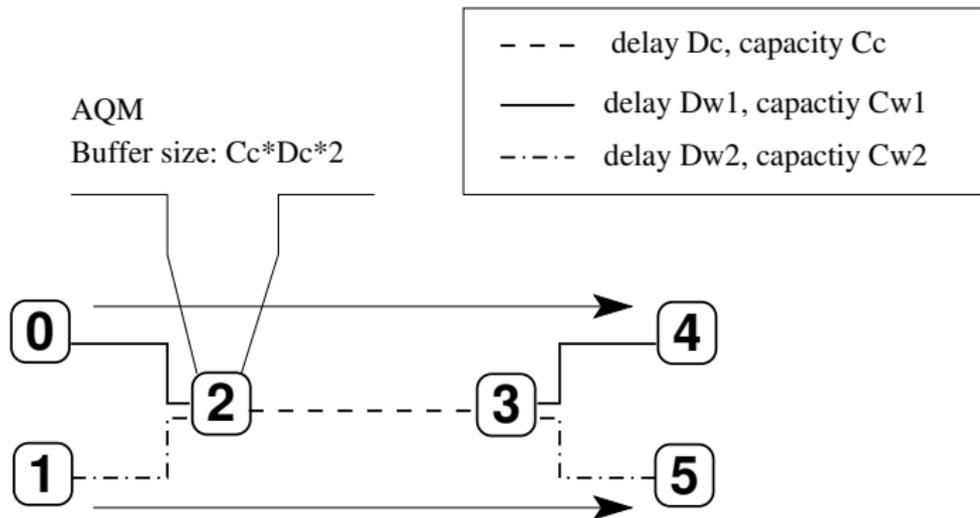

Evaluation scenarios

- provide set of scenarios that could be considered to evaluate the AQM performance
- each scenario is a potential operating region for the tested algorithm
- an evaluation report on a given AQM should make it clear when the parameters of an AQM had to be externally adjusted for the AQM to perform on various scenarios
- for each scenario, the tester should exploit the metrics presented earlier
- the evaluation scenarios can be divided into two classes :
 - generic scenarios that **must** be considered
 - specific network environments scenarios that **could** be considered to evaluate the performance of an AQM in particular conditions
- objective of this presentation :
 - justify and detail the scenarios
 - discuss which scenario **MUST** and which **MAY** be considered
 - agree on a structure for the performance evaluation
 - detailed topology or traffic modelisation may not be discussed here, but comments are welcome on the aqm-list

Methodology

- sufficiently detailed description of the test setup should be provided (that would allow other to replicate the tests)
- the test setup MAY include software and hardware versions (in case they impact on the AQM performance).
- the tester MAY make its data available ?
- the guidelines are not bound to a particular evaluation tool set, however :
 - proposals SHOULD (MUST ?) be experimented on real systems ;
 - proposals MAY be evaluated with event-driven simulations (such as NS-2, NS-3, OMNET, etc.).

Topology

- classical dumbbell network
- AQM in the router before the bottleneck
- the (RTT, Capacity) of each link is independent from the others
- size of the buffer should be carefully set, considering the bandwidth-delay product

Generic scenarios - Traffic profiles

- Why this scenario ?

- applications run over different flavors of TCP (unresponsive flows (UDP ...), or aggressive flows)
- AQM should ensure queuing delay is under control with traffic profiles

- Traffic profiles

Case 1	TCP-friendly Sender	TCP New Reno or others
Case 2	aggressive Transport Sender	TCP Cubic or others
Case 3	unresponsive Transport Sender	UDP flows
Case 4	TCP initial congestion window	mix of TCP New Reno, TCP Cubic with IW3 and IW10
Case 5	traffic mix	TCP transfer, HTTP traffic, VoIP Gaming, CBR, adaptive video streaming

- Output

- (at the AQM level) queuing delay vs. link utilization vs. drop rate
- (e2e level) end-to-end delay vs. goodput vs. drop rate

Generic scenarios - Burst absorption

- Why this scenario ?

- Bursty packet arrivals
- queuing delay spikes must be minimized
- performance penalties (losses) for ongoing flows must be minimized

- Traffic profiles

- Bursty traffic :

Generic	<ul style="list-style-type: none"> • one CBR (UDP) traffic • one repeating TCP transfer • burst of packets (with various sizes of burst)
Realistic	<ul style="list-style-type: none"> • one CBR (UDP) traffic • repeating TCP transfer (IW10) • HTTP web traffic • bursty video frames

- Output

- (at the AQM level) queuing delay vs. link utilization vs. drop rate
- (e2e level) end-to-end delay vs. goodput vs. drop rate
- flow completion time
- Jitter, latency

Generic scenarios - Inter-RTT and intra-protocol fairness

- **Why this scenario ?**
 - asymmetry (various RTT) SHOULD be considered : fairness between the flows
 - AQM must be evaluated against a set of RTT
- **Topology**
 - To evaluate inter-RTT fairness :
 - flows with RTT in [5ms;100ms]
 - flows with RTT in [100ms;200ms]
 - To evaluate intra-protocol fairness :
 - flows with RTT in [5ms;200ms]
- **Output**
 - (at the AQM level) queuing delay vs. link utilization vs. drop rate
 - (e2e level) end-to-end delay vs. goodput vs. drop rate

Generic scenarios - Fluctuating network conditions

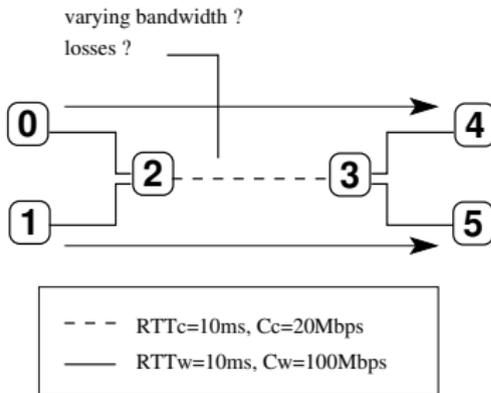

- **Why this scenario?**
 - varying operating conditions (time of day or deployment scenario)
 - stability of the AQM's parameters over time is challenged
- **Traffic profiles**
 - mild congestion
 - medium congestion
 - heavy congestion
 - varying available bandwidth
- **Output**
 - (at the AQM level) queuing delay vs. link utilization vs. drop rate
 - (e2e level) end-to-end delay vs. goodput vs. drop rate

Diverse network environments - Medium bandwidth, medium delay

- **Why this scenario ?**

- this scenario is introduced to carefully evaluate AQM proposals in a generic context
- the tester COULD consider this use case to define the operating region of the AQM

- **Toopology and Traffic profiles**

- **Traffic :**

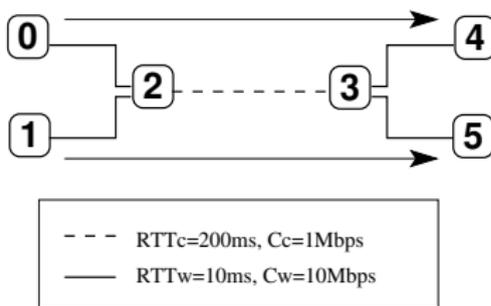

- repeating TCP transfers
- continuous TCP transfer
- HTTP web traffic

- **Output**

- (at the AQM level) queuing delay vs. link utilization vs. drop rate
- (e2e level) end-to-end delay vs. goodput vs. drop rate

Diverse network environments - Low bandwidth, high delay

- Why this scenario?
 - low bandwidth and high delay : seriously challenged burst absorption capacity
 - this use case : operating region of the AQM
- Topology and Traffic profiles

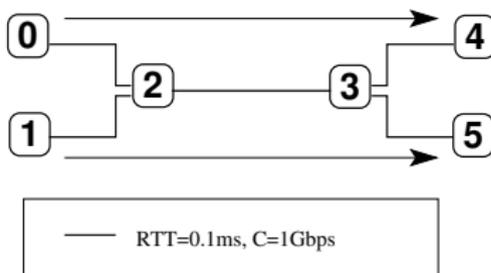

- Traffic :
 - repeating TCP transfers
 - continuous TCP transfer
 - HTTP web traffic
- Output
 - (at the AQM level) queuing delay vs. link utilization vs. drop rate
 - (e2e level) end-to-end delay vs. goodput vs. drop rate

Diverse network environments - High bandwidth, low delay

- Why this scenario ?

- high bandwidth and low delay : may require updated thresholds, auto-tuning of an AQM is challenged
- this use case : define an operating region of the AQM

- Topology and Traffic profiles

- Traffic :
 - repeating TCP transfers

- Output

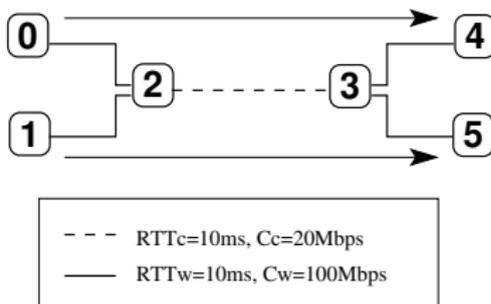

- (at the AQM level) queuing delay vs. link utilization vs. drop rate
- (e2e level) end-to-end delay vs. goodput vs. drop rate

Diverse network environments - Small and large buffers

- **Why this scenario ?**

- size of the buffers impacts on AQMs performance (even if based on queue length or queuing delay)
- low buffer (i.e. 1/10 BDP) and large buffer (i.e. 10 BDP)

- **Toopology and Traffic profiles**

- **Traffic :**

- repeating TCP transfers
- continuous TCP transfer
- HTTP web traffic

- **Output**

- (at the AQM level) queuing delay vs. link utilization vs. drop rate
- (e2e level) end-to-end delay vs. goodput vs. drop rate

Performance evaluation : are we missing anything ?

- Scenarios that **MUST** be considered :
 - various traffic profiles (unresponsive flows, aggressive flows, etc.)
 - burst absorption capacity
 - inter-RTT and intra-protocol fairness
 - fluctuating network conditions
- Scenarios that **MAY** be considered :
 - medium bandwidth, medium delay
 - low bandwidth, high delay
 - high bandwidth, low delay
 - small and large buffers
- are we missing anything ?

Table of contents

- 1 Context and objectives
- 2 Metrics
 - Queue-related metrics
 - End-to-end metrics
- 3 Evaluation scenarios
 - Methodology
 - Topology
 - Generic scenarios
 - Diverse network environments
- 4 **Deployment**
 - Operator control knobs and auto-tuning
 - Parameter sensitivity and stability analysis
 - Implementation cost
 - Interaction with packet scheduling
 - ECN behavior
 - Packet sizes and congestion notification
- 5 Comparing AQMs

Deployment

- This section details deployment issues that **MUST** be discussed (such as stability, implementation cost, implementation feasibility, control knob)
- This section helps to discuss how safe is it deploy the proposal compared to the issues encountered by RED

Operator control knobs and auto-tuning

- **Requirements**

- an AQM scheme should be stable in varying conditions without the need for external tuning (employing auto-tuning if needed)
- an AQM scheme should minimize the control knobs exposed for operator tuning, to be more user-friendly and easier to deploy and debug

Parameter sensitivity and stability analysis

• Requirements

- AQM proposals SHOULD (MAY ?) provide background material to discuss its stability
- AQM proposals SHOULD (MAY ?) provide the input parameter space within the AQM operates as expected
- for parameters that are auto-tuned, the material SHOULD (MAY ?) include stability analysis of the auto-tuning mechanism(s) as well
- the impact of every externally tuned parameter MUST be discussed
- these guidelines discourage unnecessary external tuning

Implementation cost

- **Requirements** that help identify costs associated with implementing the AQM on a particular hardware or software platform
 - AQM proposals SHOULD provide pseudo-code for the complete AQM scheme, highlighting generic implementation
 - AQM proposals SHOULD highlight parts of AQM logic that are platform dependent and discuss if and how AQM behavior could be impacted by the platform

Interaction with packet scheduling

- **Requirements**

- the tester **MUST** discuss the feasibility to add scheduling on top of its algorithm
- this discussion **MAY** detail if dropping policy is placed while packets are enqueued and dequeued

ECN behavior

- **Requirements**

- An AQM scheme **SHOULD** support ECN
- An AQM **SHOULD** leverage ECN as an initial means to control queuing delay before resorting to packet drops
- An AQM scheme **SHOULD** self-adapt and remain stable even with faulty and/or unresponsive ECN implementations

Packet sizes and congestion notification

- **Requirements**

- An AQM scheme SHOULD adhere to recommendations outlined in [I-D.ietf-tsvwg-byte-pkt-congest]
- SHOULD NOT provide undue advantage to flows with smaller packets

Deployment : are we missing anything ?

- operator control knobs and auto-tuning
- parameter sensitivity and stability analysis
- implementation cost
- interaction with packet scheduling
- ECN behavior
- packet sizes and congestion notification
- are we missing anything ?

Table of contents

- 1 Context and objectives

 - Interaction with packet scheduling
 - ECN behavior
 - Packet sizes and congestion notification
- 5 Comparing AQMs

Comparing AQMs

- the guidelines mentioned above may be used for comparing AQMs
- this memo recommends that AQM schemes **MUST** be compared against both performance and deployment categories

Comparing AQMs

• Performance

- AQM schemes **MUST** be compared against all the generic scenarios
- AQM schemes **MAY** be compared for specific network environments
- if an AQM scheme's parameter(s) were externally tuned for optimization or other purposes, these values **MUST** be disclosed
- Fair comparison of AQM schemes :
 - Problem 1 : AQM schemes belong to different varieties such as queue-length based scheme (ex :RED) or queue-delay based scheme (ex : CoDel, PIE)
 - Recommendation : Identify comparable control parameters and comparable input values (ex : qlen and target_delay)
 - Problem 2 : AQM schemes expose different control knobs associated with different semantics (ex :CoDel's "queueing delay target" and PIE's "queueing delay reference" are different)
 - Recommendation : Compare over a range of input parameters (ex : 5ms, 10ms, 15ms target delay values)

• Deployment

- all the deployment criteria discussed earlier must be considered
