

Opportunities and Research Challenges of Hybrid Software Defined Networks

Stefano Vissicchio – Université catholique de Louvain

Laurent Vanbever – Princeton University

Olivier Bonaventure – Université catholique de Louvain

SDN promises improvements...

- ▶ **Ease management**

- ▶ remove today's challenges

- ▶ Unleash additional **flexibility**

- ▶ more easily implement complex policies
- ▶ support Network Function Virtualization

- ▶ **Be real**

- ▶ commodity hardware
 - ▶ growing industrial interest
-

...by relying on architectural changes

- ▶ **homogeneous** devices
- ▶ with API for programmability

...by relying on architectural changes

The SDN proposal

- ▶ **New paradigm**
 - ▶ centralized computation
 - ▶ programmatic interface to forwarding
 - ▶ **New abstractions**
 - ▶ declarative interface to operators
 - ▶ **New protocols**
 - ▶ new API to devices
 - ▶ **New hardware**
 - ▶ with specific capabilities, e.g., match any packet field
-

New solutions → new tradeoffs

▶ Reaction to failures

- ▶ querying the controller [Sharma13] → complex controller, communication overhead, expensive out-of-band network
- ▶ pre-installing backup flow entries [Reitblatt13] → more complex protocols and hardware, not arbitrarily scalable

▶ Scalability

- ▶ distributed controllers [Koponen10] → instance synchronization, state consistency

▶ Communication with the SDN controller

- ▶ state of the art out-of-band network → expensive, doubles the network problems
-

Something to save from good old days?

- ▶ **Distributed protocols provide robustness**
 - ▶ per-device control-plane is a form a robustness
 - ▶ local reactions, seamless convergence techniques
 - ▶ e.g., [Filsfils12,Aceves93,Clad13,rfc4090]
 - ▶ **Scalability is widely studied**
 - ▶ e.g., routing hierarchy + route summarization [rfc2328], route redistribution [Le07]
 - ▶ **No need to communicate with an external system**
-

What about a hybrid SDN approach?

- ▶ SDN may not be needed for everything!
 - ▶ **Hybrid SDN** = co-existence of SDN and distributed protocols
 - ▶ we focus on IGPs as distributed protocols
 - ▶ Challenge: keep only the best of each approach
 - ▶ summing resp. advantages
 - ▶ mitigating resp. limitations
 - ▶ handling the complexity of multiple paradigms
-

Different hybrid SDN models

- ▶ **Topology-based coexistence (TB)**
 - ▶ independent IGP and SDN, running on different subnetworks
 - ▶ **Class-based coexistence (CB)**
 - ▶ independent IGP and SDN, controlling different traffic classes
 - ▶ **Integration (I)**
 - ▶ SDN controlling IGP
-

TB hSDN: Basic idea

- ▶ The network is partitioned in zones
 - ▶ each device belong to only one zone
 - ▶ a zone can be managed by either SDN or IGP

TB hSDN: Opportunities

- ▶ No upgrade **costs** where unnecessary
- ▶ Fewer requirements → **easier IGP configurations**
- ▶ SDN controller manages smaller networks
 - ▶ **less complex controllers, less scalability concerns**

TB hSDN: Challenges

- ▶ Complex **paradigm interaction**
 - ▶ information exchanges needed between zones
- ▶ **Different system interfaces** in different zones

CB hSDN: Basic idea

- ▶ SDN and IGP control different traffic classes
 - ▶ on the same physical topology

CB hSDN: Basic idea

- ▶ SDN and **IGP** control different traffic classes
 - ▶ on the same physical topology

CB hSDN: Basic idea

- ▶ **SDN** and IGP control different traffic classes
 - ▶ on the same physical topology
- ▶ The controller installs **static routes** on IGP routers

CB hSDN: Basic idea

- ▶ **SDN** and IGP control different traffic flows
 - ▶ on the same physical topology
- ▶ The controller programs **forwarding** on SDN devices

CB hSDN: Opportunities

- ▶ **Enabled SDN capabilities**
 - ▶ e.g., on critical traffic
- ▶ Some traffic **offloaded from the controller**

CB hSDN: Challenges

- ▶ **Control-plane coordination**
 - ▶ e.g., to transfer control of classes from SDN to IGP
- ▶ **No unified management interface**

I hSDN: Basic idea

- ▶ SDN needs programmatic interface to devices
 - ▶ OpenFlow is an enabler for SDN
 - ▶ IGP = distributed computation of forwarding tables
 - ▶ standardized, configurable
 - ▶ What about using IGP as an API for SDN?
 - ▶ declaring forwarding requirements
 - ▶ computing paths on the SDN controller
 - ▶ implementing paths through IGP
-

I hSDN: Basic idea

- ▶ IGP forwarding depend on a logical graph
 - ▶ on a physical network

I hSDN: Basic idea

- ▶ IGP forwarding depend on a logical graph
 - ▶ on a physical network
 - ▶ the IGP builds a logical graph of adjacencies

I hSDN: Basic idea

- ▶ IGP forwarding depend on a logical graph
 - ▶ on a physical network
 - ▶ the IGP builds a logical graph of adjacencies
 - ▶ IGP forwarding paths = shortest paths on the logical graph

- ▶ What about faking the IGP topology?

- ▶ adding *fake nodes*

I hSDN: Basic idea

- ▶ What about faking the IGP topology?
 - ▶ adding *fake nodes* (e.g., to attract traffic to SDN switches)

Basic idea

- ▶ What about faking the IGP topology?
 - ▶ adding fake nodes (e.g., to attract traffic to SDN switches)
 - ▶ tweaking *fake link weights* (e.g., to adapt to traffic matrix)

I hSDN: Basic idea

► What about faking the IGP topology?

- ▶ adding fake nodes (e.g., to attract traffic to SDN switches)
- ▶ tweaking fake link weights (e.g., to adapt to traffic matrix)
- ▶ adding ***fake destinations*** (e.g., for finer-grained TE)

- ▶ No update **costs**
- ▶ More **powerful device API** than OpenFlow
 - ▶ some tasks can be delegated to IGP

I hSDN: Challenges

- ▶ Limited **SDN capabilities**
 - ▶ e.g., SDN-specific capabilities only on some paths
- ▶ **More complex API** to devices
 - ▶ e.g., IGP specific mechanisms to be managed

Take away

- ▶ Hybridization sacrifices SDN advantages to mitigate SDN limitations
 - ▶ different models, different tradeoffs
 - ▶ model combinations to further tradeoffs
 - ▶ The SDN controller can be offloaded from some tasks
 - ▶ delegating protocols and techniques working for years
 - ▶ e.g., for short-term decisions
 - ▶ but this requires interaction with traditional protocols
-

Vision

- ▶ Hybrid SDN can provide effective transitional strategies
 - ▶ deployable today
 - ▶ provides incentives for transition to SDN
 - ▶ reduces transitional costs
 - ▶ Hybrid SDN can be an interesting network design point
 - ▶ combining SDN innovation and flexibility with well known and proven guarantees of distributed protocols
-

Network management is hard today

- ▶ Distributed computation
 - ▶ Indirect control of forwarding decisions
 - ▶ Low-level configuration languages
 - ▶ Limited flexibility in the configuration knobs
-

...by relying on architectural changes

Topology-Based (TB) Hybrid SDN

Basic idea

- ▶ The network is divided in zones
 - ▶ a zone can be managed by either SDN or IGP

Basic idea

- ▶ The network is divided in zones
 - ▶ a zone can be managed by either SDN or IGP
- ▶ Information exchanges needed between zones
 - ▶ we assume route redistribution

Pros and cons

- ▶ Local SDN controllers naturally match zones
 - ▶ Automatic failure recovery in the IGP zones
 - ▶ Improved scalability via aggregated route redistribution
 - ▶ ...
-
- ▶ SDN capabilities are limited to SDN zones
 - ▶ Additional complexity of route redistribution [Le07]
 - ▶ ...
-

Pros and cons

- ▶ Local SDN controllers naturally match zones
 - ▶ Automatic failure recovery in the IGP zones
 - ▶ Improved scalability via aggregated route redistribution
 - ▶ ...
-
- ▶ SDN capabilities are limited to SDN zones
 - ▶ Additional complexity of route redistribution [Le07]
 - ▶ **per-packet consistent update**
 - ▶ ...
-

Single zone updates

- ▶ Does the presence of other zones impact the update of a single zone?

Single zone updates

- ▶ Does the presence of other zones impact the update of a single zone? ***YES, unfortunately***

Safe techniques can be disrupted

- ▶ The update can affect forwarding in non-updated zones
 - ▶ multiple zones → conflicting preferences on the borders
 - ▶ redistributed routes → inconsistencies in non-updated zones
 - ▶ Forwarding anomalies can occur in the update
 - ▶ i.e., forwarding loops → traffic losses
 - ▶ in remote zones or across different zones
 - ▶ with safe techniques that change protocol preferences (e.g., [Herrero10, Vanbever11])
-

Multi-zone updates

- ▶ How to perform updates spanning multiple zones?

Known techniques are not easy to extend

- ▶ **Additional update knobs**
 - ▶ activating / de-activating route redistribution
 - ▶ **Additional interactions to be considered**
 - ▶ route selection → route redistribution → route availability → route selection
 - ▶ **Intermediate forwarding paths**
 - ▶ intermediate routes can leak from one zone to another
-

Safe updates are possible

- ▶ Generalized single-zone techniques
 - ▶ with additional constraints on update operations
 - ▶ Multiple-zone procedures
 - ▶ based new sufficient conditions for route redistribution correctness
 - ▶ Prototype system
 - ▶ which automates the procedures
-

Safe updates are possible

- ▶ Generalized single-zone techniques
 - ▶ with additional constraints on update operations
- ▶ Multiple-zone procedures
 - ▶ based new sufficient conditions for route redistribution correctness
- ▶ Prototype system
 - ▶ which automates the procedures

our techniques are provably correct and do not require to duplicate forwarding entries

No packet loss with our procedures

Service-Based (SB) Hybrid SDN

Pros and cons

- ▶ IGP and SDN can provide different services
 - ▶ Automatic failure recovery for IGP controlled flows
 - ▶ SDN controller off-loaded for non-critical flows
 - ▶ ...
-
- ▶ SDN capabilities are limited by the SDN devices
 - ▶ Additional complexity of parallel paradigms
 - ▶ ...
-

Pros and cons

- ▶ IGP and SDN can provide different services
 - ▶ Automatic failure recovery for IGP controlled flows
 - ▶ SDN controller off-loaded for non-critical flows
 - ▶ ...
-
- ▶ SDN capabilities are limited by the SDN devices
 - ▶ Additional complexity of parallel paradigms
 - ▶ **per-packet consistent update**
 - ▶ ...
-

Update of SB hybrid networks

- ▶ SDN-controlled flows \leftrightarrow IGP-controlled flows
 - ▶ e.g., because a service/dest becomes critical
 - ▶ e.g., in response to traffic matrix changes
 - ▶ Inconsistencies can occur during the update
 - ▶ forwarding loops
 - ▶ intermediate forwarding paths
 - ▶ access policy violation, congestion, TCP issues, ...
-

Safe updates are possible

- ▶ **Mixed update approach**
 - ▶ update sequencing algorithm + fallback solutions
 - ▶ to limit forwarding entry duplication
 - ▶ **Algorithm to compute maximal safe update sequences**
 - ▶ typically, most routers can be updated w/o forwarding duplication
 - ▶ **Fallback solutions**
 - ▶ applied only when a complete update sequence does not exist
-

Safe updates w/o forwarding doubling

Pros and Cons

▶ Pros

- ▶ Local SDN controllers can be distributed to different zones
- ▶ Automatic failure recovery in the IGP zones
- ▶ Improved scalability through aggregated route redistribution
- ▶ ...

▶ Cons

- ▶ SDN capabilities are limited to SDN zones
 - ▶ additional complexity of route redistribution [Le07]
 - ▶ per-packet consistent updates
 - ▶ ...
-

- ▶ SDN and IGP control different traffic flows
 - ▶ on the same physical topology
- ▶ The controller installs static routes on IGP routers

Pros and Cons

▶ Pros

- ▶ IGP faking is powerful
 - ▶ we can modify the IGP graph for per-flow forwarding paths, traffic steering, load balancing on paths and on middle-boxes
 - ▶ except violations of the shortest path rules on chains of IGP routers
- ▶ controlled reaction to failures
 - ▶ backup paths can be explicitly realized

▶ Cons

- ▶ SDN capability depends on the deployed OF switches
 - ▶ traffic must flow through them
 - ▶ increased size of the new IGP graph
-

Integrated Hybrid SDN

Pros and cons

- ▶ IGP faking is powerful
 - ▶ per-flow traffic engineering, load balancing, middleboxing
 - ▶ controlled reaction to failures (e.g., backup paths)
 - ▶ Safe update by tweaking the fake IGP graph
 - ▶ easily re-route many flows
 - ▶ ...
 - ▶ SDN capability limited by SDN devices
 - ▶ Increased size of the new IGP graph
 - ▶ ...
-

Pros and cons

- ▶ IGP faking is powerful
 - ▶ per-flow traffic engineering, load balancing, middleboxing
 - ▶ controlled reaction to failures (e.g., backup paths)
 - ▶ Safe update by tweaking the fake IGP graph
 - ▶ easily re-route many flows
 - ▶ ...
 - ▶ SDN capability limited by SDN devices
 - ▶ **Increased size of the new IGP graph**
 - ▶ ...
-

IGP faking made practical

- ▶ Path requirement language
 - ▶ specifying the shape of {primary, ECMP, backup} paths
 - ▶ on a per-flow granularity
 - ▶ LP algorithm to compute a minimal fake graph
 - ▶ Prototype to realize path requirements
 - ▶ from the language to a minimal fake IGP graph
-

Take away

- ▶ Hybrid SDN can be an effective transitional mechanism
 - ▶ deployable today → reduces deployment costs
 - ▶ provides incentives for transition to SDN
 - ▶ Hybrid SDN can be an interesting design point
 - ▶ hybridization sacrifices some SDN capabilities to mitigate some SDN limitations
 - ▶ it can combine the SDN innovation and flexibility with basic guarantees of distributed protocols
 - ▶ different hybridization models fit different networks
-

Comparison of Hybrid SDN Models

- ▶ Hybridization sacrifices some SDN capabilities to mitigate some SDN limitations
 - ▶ different models → different tradeoffs

	SDN capabilities	Network Update	Controller Scalability	Costs
TB H-SDN	local to SDN zones	carefully defined procedures	SDN spans a subset of devices	progressive with the number of SDN devices
SB H-SDN	depend on the SDN devices	carefully defined procedures	SDN controls a subset of flows	
Integrated	depend on the SDN devices	carefully defined fake topologies	proactive faking for given “events”
