NVO3 Operations, Administration, and Maintenance Requirements
draft-ashwood-nvo3-oam-requirements-04

Abstract

This document provides framework and requirements for Network Virtualization Overlay (NVO3) Operations, Administration, and Maintenance (OAM).

Status of this Memo

This Internet-Draft is submitted to IETF in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at
<http://www.ietf.org/lid-abstracts.html>

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>

1. Introduction

This document provides framework and requirements for Network Virtualization Overlay (NVO3) Operations, Administration, and Maintenance (OAM). Given that this OAM subject is far from new and has been under extensive investigation by various IETF working groups (and several other standards bodies) for many years, this document draws from existing work, starting with [RFC6136]. As a result, sections of [RFC6136] have been reused with minor changes with the permission of the authors.

NVO3 OAM requirements are expected to be a subset of IETF/IEEE etc. work done so far; however, we begin with a full set of requirements and expect to prune them through several iterations of this document.

1.1. OSI Definitions of OAM

The scope of OAM for any service and/or transport/network infrastructure technologies can be very broad in nature. OSI has defined the following five generic functional areas commonly abbreviated as "FCAPS" [NM-Standards]:

- o Fault Management,
- o Configuration Management,
- o Accounting Management,
- o Performance Management, and
- o Security Management.

This document focuses on the Fault, Performance and to a limited extent the Configuration Management aspects. Other functional aspects of FCAPS and their relevance (or not) to NVO3 are for further study.

Fault Management can typically be viewed in terms of the following categories:

- o Fault Detection;
- o Fault Verification;
- o Fault Isolation;
- o Fault Notification and Alarm Suppression;

- o Fault Recovery.

Fault detection deals with mechanism(s) that can detect both hard failures such as link and device failures, and soft failures, such as software failure, memory corruption, misconfiguration, etc. Fault detection relies upon a set of mechanisms that first allow the observation of an event, then the use of a protocol to dynamically notify a network/system operator (or management system) about the event occurrence, then the use of diagnostic tools to assess the nature and severity of the fault.

After verifying that a fault has occurred along the data path, it is important to be able to isolate the fault to the level of a given device or link. Therefore, a fault isolation mechanism is needed in Fault Management. A fault notification mechanism should be used in conjunction with a fault detection mechanism to notify the devices upstream and downstream to the fault detection point. The fault notification mechanism should also notify NMS systems.

The terms "upstream" and "backward" are used here to denote the direction(s) from which data traffic is flowing. The terms "downstream" and "forward" denote the direction(s) to which data traffic is forwarded.

For example, when there is a client/server relationship between two layered networks (e.g., the NVO3 layer is a client of the outer IP server layer, while the inner IP layer is a client of the NVO3 server layer 2), fault detection at the server layer may result in the following fault notifications:

- o Sending a forward fault notification from the server layer to the client layer network(s) using the fault notification format appropriate to the client layer.
- o Sending a backward fault notification to the server layer, if applicable, in the reverse direction.
- o Sending a backward fault notification to the client layer, if applicable, in the reverse direction.

Finally, fault recovery deals with recovering from the detected failure by switching to an alternate available data path (depending on the nature of the fault) using alternate devices or links. In fact, the controller can provision another virtual network, thus automatically resolving the reported problem.

The controller may also directly monitor the status of virtual network components such as Network Virtualization Edge elements

(NVEs) [RFC7365] in order to respond to their failures. In addition to forward and backward fault notifications, the controller may deliver notifications to a higher level orchestration component, e.g., one responsible for Virtual Machine (VM) provisioning and management.

Note, given that the IP network on which NVO3 resides is usually self healing, it is expected that recovery by the NVO3 layer would not normally be required, although there may be a requirement for that layer to log that the problem has been detected and resolved. The special cases of a static IP overlay network, or possibly of a centrally controlled IP overlay network, may, however, require NVO3 involvement in fault recovery.

Performance Management deals with mechanism(s) that allow determining and measuring the performance of the network/services under consideration. Performance Management can be used to verify the compliance to both the service-level and network-level metric objectives/specifications. Performance Management typically consists of measuring performance metrics, e.g., Frame Loss, Frame Delay, Frame Delay Variation (aka Jitter), Frame Throughput, Frame Discard, etc., across managed entities when the managed entities are in available state. Performance Management is suspended across unavailable managed entities.

1.2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

1.3. Relationship with Other OAM Work

This document leverages requirements that originate with other OAM work, specifically the following:

- o [RFC6136] provides a template and some of the high level requirements and introductory wording.
- o [IEEE802.1Q-2011] is expected to provide a subset of the requirements for NVO3 both at the Tenant level and also within the L3 Overlay network.
- o [Y.1731] is expected to provide a subset of the requirements for NVO3 at the Tenant level.
- o Section 3.3.2.1 of [NVO3-DP-Reqs] lists several requirements specifically concerning ECMP/LAG.

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

The terminology defined in [RFC7365] and [NVO3-DP-Reqs] is used throughout this document. We introduce no new terminology.

3. NVO3 Reference Model

Figure 1 below reproduces the generic NVO3 reference model as per [RFC7365].

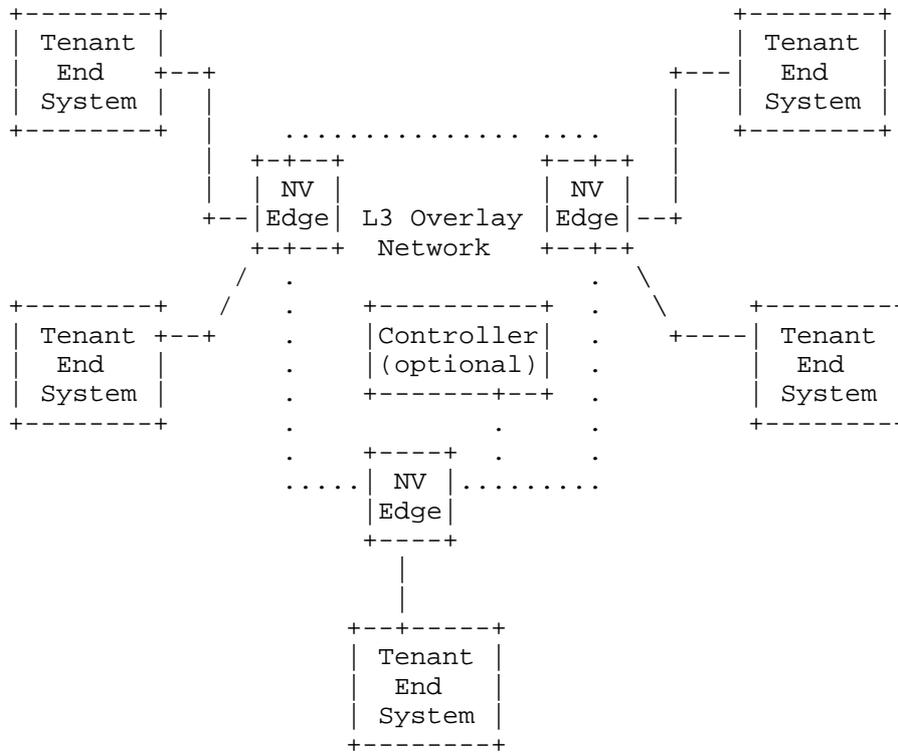

Figure 1: Generic NVO3 Reference Model

Figure 2 below, reproduces the Generic reference model for the NV Edge (NVE) as per [NVO3-DP-Reqs].

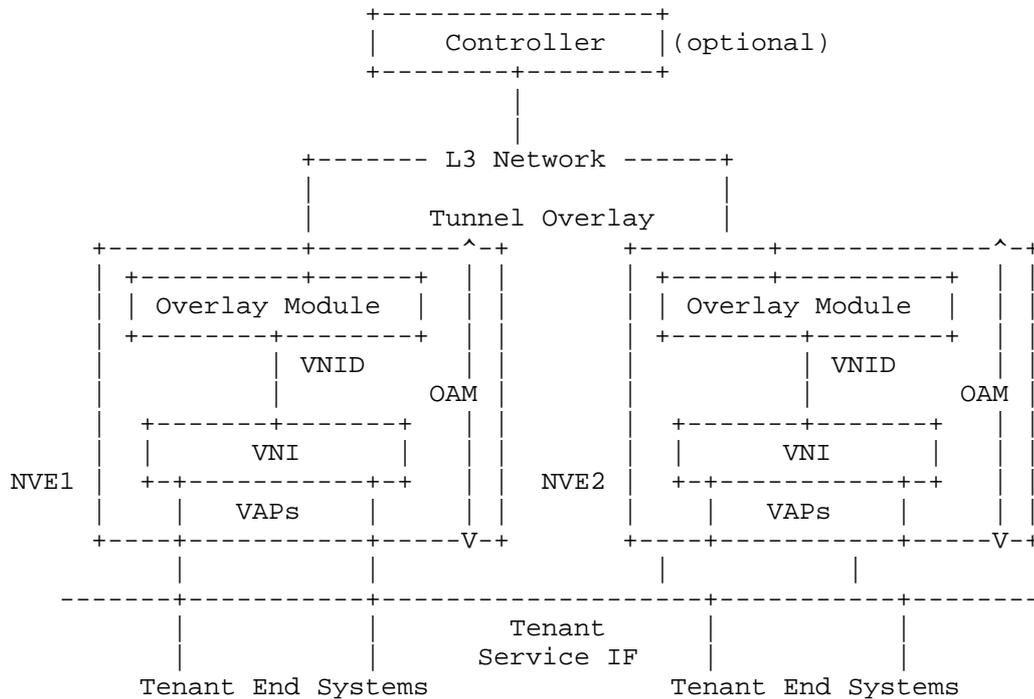

Figure 2: Generic reference model for the NV Edge (NVE)

4. OAM Framework for NVO3

Figure 1 shows the generic reference model for a DC network virtualization over an L3 (or L3VPN) infrastructure while Figure 2 showed the generic reference model for the Network Virtualization (NV) Edge. As shown in both figure 1 and figure 2, the Controller is an optional element that can participate to the support and the operation of OAM functions.

L3 network(s) or L3 VPN networks (either IPv6 or IPv4, or a combination thereof), provide transport for an emulated layer 2 created by NV Edge devices. Unicast and multicast tunneling methods (de-multiplexed by Virtual Network Identifier (VNID)) are used to provide connectivity between the NV Edge devices. The NV Edge devices then present an emulated layer 2 network to the Tenant End Systems at a Virtual Network Interface (VNI) through Virtual Access Points (VAPs). The NV Edge devices map layer 2 unicast to layer 3 unicast point-to-point tunnels and may either map layer 2 multicast to layer 3 multicast tunnels or may replicate packets onto multiple layer 3 unicast tunnels.

4.1. OAM Layering

The emulated layer 2 network is provided by the NV Edge devices to which the Tenant End Systems are connected. This network of NV Edges can be operated by a single service provider or can span across multiple administrative domains. Likewise, the L3 Overlay Network can be operated by a single service provider or span across multiple administrative domains.

While each of the layers is responsible for its own OAM, each layer may consist of several different administrative domains. Figure 3 shows an example.

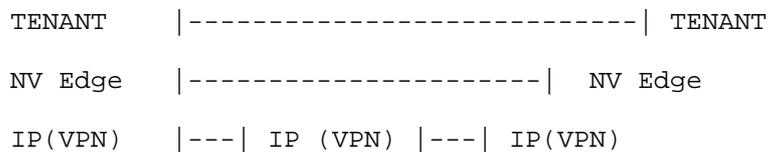

Figure 3: Example NVO3 OAM Layering

For example, at the bottom, at the L3 IP overlay network layer IP(VPN) and/or Ethernet OAM mechanisms are used to probe link by link, node to node etc. OAM addressing here means physical node loopback or interface addresses.

Further up, at the NV Edge layer, NVO3 OAM messages are used to probe the NV Edge to NV Edge tunnels and NV Edge entity status. OAM addressing here likely means the physical node loopback together with the VNI (to de-multiplex the tunnels).

Finally, at the Tenant layer, the IP and/or Ethernet OAM mechanisms are again used but here they are operating over the logical L2/L3 provided by the NV-Edge through the VAP. OAM addressing at this layer deals with the logical interfaces on Vswitches and Virtual Machines.

4.2. OAM Domains

Complex OAM relationships exist as a result of the hierarchical layering of responsibility and of breaking up of end-to-end responsibility.

The OAM domain above NVO3, is expected to be supported by existing IP and L2 OAM methods and tools.

The OAM domain below NVO3, is expected to be supported by existing IP/L2 and MPLS OAM methods and tools. Where this layer is actually

multiple domains spliced together, the existing methods to deal with these boundaries are unchanged. Note however that exposing LAG/ECMP detailed behavior may result in additional requirements to this domain, the details of which will be specified in the future versions of this draft.

When we refer to an OAM domain in this document, or just 'domain', we therefore refer to a closed set of NV Edges or MEPs and the tunnels which interconnect them.

Note, whether for the scenario of inter-domain or multi-layer, each domain (or layer) is responsible for its own OAM, no correlation of OAM function exists between each domain (or layer). When an E2E connection in Tenant layer spans across multiple domains and has multiple underlay layers of NV Edge layer and L3 IP (VPN) layer, current OAM implementation for the E2E connection of Tenant layer such as Fault or Performance Management can only be performed per domain and layer manually and more manual labor is needed. An automatic coordination process among OAM functions of each domain or layer may be useful here for improving efficiency and intelligence.

In the case where a gateway device is use to connect two different domains (whether for changing the encapsulation or other reasons), it is necessary to provide mechanisms to monitor the path through the gateway which involves the removal of one overlay header and the creation of a new one.

5. NVO3 OAM Requirements

5.1. Discovery

R1) NVO3 OAM MUST allow an NV Edge device to dynamically discover other NV Edge devices that share the same VNI within a given NVO3 domain. This may be based on a discovery mechanism used to set up data path forwarding between NVEs.

5.2. Connectivity Fault Management

5.2.1. Connectivity Fault Detection

R2) NVO3 OAM MUST allow proactive connectivity monitoring between two or more NV Edge devices that support the same VNIs within a given NVO3 domain. NVO3 OAM MAY act as a protection trigger. That is, automatic recovery from transmission facility failure by switchover to a redundant replacement facility may be triggered by notifications from NVO3 OAM.

R3) NVO3 OAM MAY allow monitoring/tracing of all possible paths in the underlay network between a specified set of two or more NV Edge devices. Using this feature, equal cost paths that traverse LAG and/or ECMP may be differentiated.

5.2.2. Connectivity Fault Verification

R4) NVO3 OAM MUST allow connectivity fault verification between two or more NV Edge devices that support the same VNI within a given NVO3 domain.

5.2.3. Connectivity Fault localization

R5) NVO3 OAM MUST allow connectivity fault localization between two or more NV Edge devices that support the same VNI within a given NVO3 domain.

5.2.4. Connectivity Fault Notification and Alarm Suppression

R6) NVO3 OAM MUST support fault notification to be triggered as a result of the faults occurring in the underneath network infrastructure. This fault notification SHOULD be used for the suppression of redundant service-level alarms.

5.3. Connectivity Performance Management

5.3.1. Frame Loss

R7) NVO3 OAM MUST support measurement of per VNI frame loss between two NV Edge devices that support the same VNI within a given NVO3 domain.

5.3.2. Frame Delay

R8) NVO3 OAM MUST support measurement of per VNI two-way frame delay between two NV edge devices that support the same VNI within a given NVO3 domain.

R9) NVO3 OAM MUST support measurement of per VNI one-way frame delay between two NV Edge devices that support the same VNI within a given NVO3 domain.

5.3.3. Frame Delay Variation

R10) NVO3 OAM MUST support measurement of per VNI frame delay variation between two NV Edge devices that support the same VNI

within a given NVO3 domain.

5.3.4. Frame Throughput

R11) NVO3 OAM MAY support measurement of per VNI frame throughput (in frames and bytes) between two NV Edge devices that support the same VNI within a given NVO3 domain. This feature could be an effective way to confirm whether or not assigned path bandwidth conforms to service level agreement before providing the path between two NV Edge devices.

5.3.5. Frame Discard

R12) NVO3 OAM MAY support measurement of per VNI frame discard between two NV Edge devices that support the same VNI within a given NVO3 domain. This feature MAY be effective to monitor bursty traffic between two NV Edge devices.

5.4. Continuity Check

NVO3 OAM MUST provide functions that allow any arbitrary NV edge device to perform a Continuity Check to any other NV edge device.

NVO3 OAM MUST provide functions that allow any arbitrary NV edge device to perform a Continuity Check to any other NV edge device using a path associated with a specified flow.

NVO3 OAM SHOULD provide functions that allow any arbitrary NV edge device to perform a Continuity Check to any other NV edge device over any section of any selectable least-cost path.

NVO3 OAM SHOULD provide the ability to perform a Continuity Check on sections of any selectable path within the network.

5.5. Availability

A service may be considered unavailable if the service frames/packets do not reach their intended destination (e.g., connectivity is down) or the service is degraded (e.g., frame loss and/or frame delay and/or delay variation threshold is exceeded). Entry and exit conditions may be defined for the unavailable state. Availability itself may be defined in the context of a service type. Since availability measurement may be associated with connectivity, frame loss, frame delay, and frame delay variation measurements, no additional requirements are specified currently.

5.6. Data Path Forwarding

R13) NVO3 OAM frames MUST be forwarded along the same path (i.e., links (including LAG members) and nodes) as the NVO3 data frames.

R14) NVO3 OAM frames MAY provide a mechanism to exercise/trace all data paths that result due to ECMP/LAG hops in the underlay network, if these paths have been known.

NVO3 OAM frame MUST be possible arranged to follow the path taken by a specific flow.

NVE MUST have the ability to identify frames that require OAM processing.

The Controller element MAY be involved in the out-of-band OAM design and deployment. Indeed, the Controller is expected to maintain an up-to-date global, systemic view of all the network paths and their associated status (e.g., available, idle, unavailable, faulty, in maintenance, etc.)

5.7. Scalability

R15) NVO3 OAM MUST be scalable such that an NV edge device can support proactive OAM for each VNI that is supported by the device.

5.8. Extensibility

R16) NVO3 OAM should be extensible such that new functionality and information elements related to this functionality can be introduced in the future.

R17) NVO3 OAM MUST be defined such that devices not supporting the OAM are able to forward the OAM frames in a similar fashion as the regular NVO3 data frames/packets.

5.9. Security

R18) NVO3 OAM frames MUST be prevented from leaking outside their NVO3 domain.

R19) NVO3 OAM frames from outside an NVO3 domain MUST be prevented from entering the said NVO3 domain when such OAM frames belong to the same level or to a lower-level OAM. (Trivially met because hierarchical domains are independent technologies.)

R20) NVO3 OAM frames from outside an NVO3 domain MUST be transported transparently inside the NVO3 domain when such OAM frames belong to a higher-level NVO3 domain. (Trivially met)

because hierarchical domains are independent technologies).

5.10. Transport Independence

Similar to transport requirement from [RFC6136], we expect NVO3 OAM will leverage the OAM capabilities of the transport layer (e.g., IP underlay).

R21) NVO3 OAM MAY allow adaptation/interworking with its IP underlay OAM functions. For example, this would be useful to allow fault notifications from the IP layer to be sent to the NVO3 layer. Likewise, LAG/ECMP-originated notifications may affect the NVO3 OAM decision process.

5.11. Application Independence

R22) NVO3 OAM MAY be independent of the application technologies and specific application OAM capabilities.

5.12. Prioritization

R23) NVO3 OAM messages MUST be preferentially treated in NVE and between NVEs, since NVO3 OAM MAY be used to trigger protection switching. As noted above (R2), protection switching is the automatic replacement of a failed transmission facility with a working one providing equal or greater capacity, typically within a few tens of milliseconds from fault detection.

5.13. Logging and Traceability Requirements

Logging is required at the Network Virtualization Authority (NVA) and the Network Virtualization Edge (NVE) [and the NVO3 Gateway, but the framework does not mention such a beast] in support of fault management and configuration management.

R24) All logs MUST contain a (sufficiently accurate) timestamp to allow the reporting functional instance (i.e., NVA, NVE) to precisely determine the sequence of events. Clocks on different functional instances SHOULD be synchronized to allow similar accuracy when comparing logs from different devices.

R25) All logs MUST contain information that unambiguously identifies the reporting functional instance

R26) Implementations MUST be capable of reporting the following fault-related events:

1. Loss and resumption of connectivity

These reports SHOULD identify the affected VNI(s), but when the loss affects a large number of VNIs simultaneously the report SHOULD identify the underlying entity (e.g., route) if available.

2. Loss and resumption of NVE responsiveness

These reports will be generated by adjacent NVAs or NVEs. They MUST identify the NVE concerned.

3. NVA or NVE change of operational state

These reports will be generated by the NVA or NVE concerned. They MUST indicate the old and new operational states and the cause.

4. Loss and resumption of a VAP

These reports will be generated by adjacent NVAs or NVEs. They MUST identify the VAP concerned.

R27) Implementations MUST be capable of reporting the following events in support of configuration management and auditing. It MUST be possible to generate the reports at both the originating and executing entities. The report generated at the originating entity MUST identify the executing entity and the report at the executing entity MUST identify the originating entity. Both reports MUST indicate the result of the transaction.

1. Virtual Access Point (VAP) creation or deletion

These reports MUST identify the VAP, the Tenant System, and the port supporting the VAP.

2. VNI creation or deletion

These reports MUST identify the VNI and the VAP.

3. VNI renumbering

These reports MUST identify the VAP and the old and new VNI numbers.

4. Reachability and forwarding information update

These reports MUST identify the previous and new file identifiers. (Assumption: reachability and forwarding information is passed as files, which are retained at the originating and executing

entities for a fixed period for auditing purposes.)

R28) As a general requirement, implementations MUST provide a means whereby the operator can impose rate limits on the generation of specific reports. Implementations MUST further permit the operator to totally suppress reporting of specific events. However, if any report types have been suppressed, non-suppressible reports MUST be generated at regular intervals (e.g., once an hour) indicating what report types have been suppressed.

5.14. Live Traffic Monitoring

NVO3 OAM implementations MAY provide methods to utilize live traffic for troubleshooting and performance monitoring.

6. Items for Further Discussion

This section identifies a set of operational items which may be elaborated further if these items fall within the scope of the NVO3.

- o VNID renumbering support
 - * Means to change the VNID assigned to a given instance MUST be supported.
 - * System convergence subsequent to VNID renumbering MUST NOT take longer than a few seconds, to minimize impact on the tenant systems.
 - * A NVE MUST be able to map a VNID with a virtual network context.
- o VNI migration and management operations
 - * Means to delete an existing VNI MUST be supported.
 - * Means to add a new VNI MUST be supported.
 - * Means to merge several VNIs MAY be supported.
 - * Means to retrieve reporting data per VNI MUST be supported.
 - * Means to monitor the network resources per VNI MUST be supported.
- o Support of planned maintenance operations on the NVO3 infrastructure

- * Graceful procedure to allow for planned maintenance operation on NVE MUST be supported. This includes undoing any configuration changes made for maintenance purposes after completion of the maintenance.
- o Support for communication among virtual networks
 - * For global reachability purposes, communication among virtual networks MUST be supported. This can be enforced using a NAT function.
- o Activation of new network-related services to the NVO3
 - * Means to assist in activating new network services (e.g., multicast) without impacting running service SHOULD be supported.
- o Inter-operator NVO3 considerations
 - * As NVO3 may be deployed over inter-operator infrastructure, coordinating OAM actions in each individual domain are required to ensure an end-to-end OAM. In particular, this assumes existence of agreements on the measurement and monitoring methods, fault detection and repair actions, extending QoS classes (e.g., DSCP mapping policies), etc.
- o An automatic coordination process among OAM functions of different domains or layers which an E2E connection in Tenant layer is tunneled on
 - * NVO3 OAM MAY support the automatic coordination of OAM functions among different domains or layers which belong to one Tenant layer E2E connection. The automatic coordination means OAM function in client layer or one domain triggers associated OAM functions in server layer or neighbouring domain. This triggered action performs at the domain boundaries, which is also the MEPs of the domain. Which OAM function in client layer or one domain can trigger which OAM functions in server layer or neighbouring domain depends on specific condition, and can be very flexible. But the basic rule is that the OAM functions performed simultaneously in different domains or layers can be synthesized together to get the final result.
 - * The OAM MEPs of domains MUST have the capability to know if it they need to perform the above automatic coordination process. This can be achieved by many ways, i.e., by configuration, by checking the flag field in OAM frames.

- * When the OAM MEPS perform the automatic coordination, a specific global characteristic information MUST be carried and mapped between OAM frames used in different domains or layers, and be kept the same along the whole tenant layer E2E connection. The global characteristic information can be the tenant network identifier (e.g., VNID), ICMP sequence number, etc. It is used for identifying a set of correlated OAM results obtained from these domains or layers. This set of OAM results is then synthesized together to get the final diagnose result.
- * NVO3 OAM MUST support a Collection Point for collecting all the OAM results and synthesizing them. It can be the SDN controller, NVA, or NMS. An E2E OAM function in tenant network can trigger several OAM functions in different underlay networks, a Collection Point is needed to collect all the OAM results from different OAM MEPS of different domains or layers and synthesizes them.

7. IANA Considerations

This memo includes no request to IANA.

8. Security Considerations

Security requirements are specified in Section 5.9. For general NVO3 security considerations, please refer to [NVO3-Security].

9. Acknowledgements
