This document describes the key chain YANG data model. A key chain is a list of elements each containing a key, send lifetime, accept lifetime, and algorithm. By properly overlapping the send and accept lifetimes of multiple key chain elements, keys and algorithms may be gracefully updated. By representing them in a YANG data model, key distribution can be automated. Key chains are commonly used for routing protocol authentication and other applications. In some applications, the protocols do not use the key chain element key directly, but rather a key derivation function is used to derive a short-lived key from the key chain element key.
1. Introduction

This document describes the key chain YANG data model. A key chain is a list of elements each containing a key, send lifetime, accept lifetime, and algorithm. By properly overlapping the send and accept lifetimes of multiple key chain elements, keys and algorithms may be gracefully updated. By representing them in a YANG data model, key distribution can be automated. Key chains are commonly used for routing protocol authentication and other applications. In some applications, the protocols do not use the key chain element key directly, but rather a key derivation function is used to derive a short-lived key from the key chain element key.
1.1. Requirements Notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC-KEYWORDS].

2. Problem Statement

This document describes a YANG [YANG] data model for key chains. Key chains have been implemented and deployed by a large percentage of network equipment vendors. Providing a standard YANG model will facilitate automated key distribution and non-disruptive key rollover. This will aid in tightening the security of the core routing infrastructure as recommended in [IAB-REPORT].

A key chain is a list containing one or more elements containing a Key ID, key, send/accept lifetimes, and the associated authentication or encryption algorithm. A key chain can be used by any service or application requiring authentication or encryption. In essence, the key-chain is a reusable key policy that can be referenced wherever it is required. The key-chain construct has been implemented by most networking vendors and deployed in many networks.

A conceptual representation of a crypto key table is described in [CRYPTO-KEYTABLE]. The crypto key table also includes keys as well as their corresponding lifetimes and algorithms. Additionally, the key table includes key selection criteria and envisions a deployment model where the details of the applications or services requiring authentication or encryption permeate into the key database. The YANG key-chain model described herein doesn’t include key selection criteria or support this deployment model. At the same time, it does not preclude it. The draft [YANG-CRYPTO-KEYTABLE] describes augmentations to the key chain YANG model in support of key selection criteria.

2.1. Graceful Key Rollover using Key Chains

Key chains may be used to gracefully update the key and/or algorithm used by an application for authentication or encryption. This MAY be accomplished by accepting all the keys that have a valid accept lifetime and sending the key with the most recent send lifetime. One scenario for facilitating key rollover is to:

1. Distribute a key chain with a new key to all the routers or other network devices in the domain of that key chain. The new key’s accept lifetime should be such that it is accepted during the key rollover period. The send lifetime should be a time in the future when it can be assured that all the routers in the domain...
of that key are upgraded. This will have no immediate impact on
the keys used for transmission.

2. Assure that all the network devices have been updated with the
updated key chain and that their system times are roughly
synchronized. The system times of devices within an
administrative domain are commonly synchronized (e.g., using
Network Time Protocol (NTP) [NTP-PROTO]). This also may be
automated.

3. When the send lifetime of the new key becomes valid, the network
devices within the domain of key chain will start sending the new
key.

4. At some point in the future, a new key chain with the old key
removed may be distributed to the network devices within the
domain of the key chain. However, this may be deferred until the
next key rollover. If this is done, the key chain will always
include two keys; either the current and future key (during key
rollovers) or the current and previous keys (between key
rollovers).

3. Design of the Key Chain Model

The ietf-keychain module contains a list of one or more keys indexed
by a Key ID. For some applications (e.g., OSPFv3 [OSPFV3-AUTH]), the
Key-Id is used to identify the key chain entry to be used. In
addition to the Key-ID, each key chain entry includes a key-string
and a cryptographic algorithm. Optionally, the key chain entries
include send/accept lifetimes. If the send/accept lifetime is
unspecified, the key is always considered valid.

Note that asymmetric keys, i.e., a different key value used for
transmission versus acceptance, may be supported with multiple key
chain elements where the accept-lifetime or send-lifetime is not
valid (e.g., has an end-time equal to the start-time).

Due to the differences in key chain implementations across various
vendors, some of the data elements are optional. Additionally, the
key-chain is made a grouping so that an implementation could support
scoping other than at the global level. Finally, the crypto-
algorithm-types grouping is provided for reuse when configuring
legacy authentication and encryption not using key-chains.

A key-chain is identified by a unique name within the scope of the
network device. The "key-chain-ref" typedef SHOULD be used by other
YANG modules when they need to reference a configured key-chain.
3.1. Key Chain Operational State

The key chain operational state is maintained in the key-chain entries along with the configuration state. The key string itself is omitted from the operational state to minimize visibility similar to what was done with keys in SNMP MIBs. This is an area for further discussion. Additionally, the operational state includes an indication of whether or not a key chain entry is valid for sending or acceptance.

3.2. Key Chain Model Features

Features are used to handle differences between vendor implementations. For example, not all vendors support configuration an acceptance tolerance or configuration of key strings in hexadecimal. They are also used to support of security requirements (e.g., TCP-AO Algorithms [TCP-AO-ALGORITHMS]) not implemented by vendors or only a single vendor.

3.3. Key Chain Model Tree

```
++-rw key-chains
   ++-rw key-chain-list* [name]
      |   ++-rw name                      string

5. Relationship to other Work

6. Security Considerations

This document enables the automated distribution of industry standard key chains using the NETCONF [NETCONF] protocol. As such, the security considerations for the NETCONF protocol are applicable. Given that the key chains themselves are sensitive data, it is RECOMMENDED that the NETCONF communication channel be encrypted. One way to do accomplish this would be to invoke and run NETCONF over SSH as described in [NETCONF-SSH].

When configured, the key-strings can be encrypted using the AES Key Wrap algorithm [AES-KEY-WRAP]. The AES key-encryption key (KEK) is not included in the YANG model and must be set or derived independent of key-chain configuration.

The key strings are not included in the operational state. This is a practice carried over from SNMP MIB modules and is an area for further discussion.

7. IANA Considerations

This document registers a URI in the IETF XML registry [XML-REGISTRY]. Following the format in RFC 3688, the following registration is requested to be made:

URI: urn:ietf:params:xml:ns:yang:ietf-key-chain

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.
This document registers a YANG module in the YANG Module Names registry [YANG].

YANG Data Model for RFC 7210 Key Table
<draft-chen-rtgwg-key-table-yang-02.txt>

Status of this Memo

Distribution of this memo is unlimited.

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at http://www.ietf.org/ietf/lid-abstracts.txt.

The list of Internet-Draft Shadow Directories can be accessed at http://www.ietf.org/shadow.html.

This Internet-Draft will expire in 6 months.

Abstract

RFC 7210 defines a key table that consists of cryptographic keys that stores information for many different types of routing protocols to ensure message security. This document defines a YANG data model that represents the key table defined in RFC 7210, with the information necessary for YANG and NETCONF to provide routing protocol authentication.
1. Introduction

[RFC7210] defines a standards track key table that is used to store information for routing protocol authentication, including key values, cryptographic algorithms, timing attributes, and their relationships to allow different routing protocols to perform key selection, authentication, and smooth key rollover that ultimately provides routing protocol message security. This document defines a YANG [RFC6020] data model that corresponds to [RFC7210] and enables the use of NETCONF [RFC6241] and YANG to manage routing protocol authentication data.

An earlier version of the key table YANG model [I-D.chen-rtg-key-table-yang] augments from the key-chain YANG model [I-D.acee-rtg-yang-key-chain]. However, because the key-chain YANG model organizes keys in groups, which is different from the key definitions in [RFC7210], this document proposes a new key-table YANG model that is structurally more consistent with the key database defined in [RFC7210].

1.1. Terminology

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14, [RFC2119].
1.2. Tree Diagram

A simplified graphical representation of the data model is presented in Section 2.

The meaning of the symbols in these diagrams is as follows:

- Brackets "[" and "]" enclose list keys.
- Curly braces "{" and "}" contain names of optional features that make the corresponding node conditional.
- Abbreviations before data node names: "rw" means configuration (read-write), and "ro" state data (read-only).
- Symbols after data node names: "?" means an optional node and "*" denotes a "list" or "leaf-list".
- Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (":").
- Ellipsis ("...") stands for contents of subtrees that are not shown.

2. Design of the Data Model

This data model is based on the key table defined in [RFC7210]. Because [RFC7210] defines a table that allows protocols to customize certain fields, the data model comes in two parts, the base model and the customizable part. The base model defines the attributes in [RFC7210] that are immutable across all protocols, such as admin-key-name and send-lifetime-start. The customizable part defines the attributes that are different across protocols, such as the local-key-name, peer-key-name, and peers field. These customizable attributes are defined as YANG grouping statements that can be used and incorporated into protocol-specific key table modules.

2.1. Base Model

[RFC7210] defines a single table in which the rows represent the individual key entries of the key table. As such, the base model consists of one single top-level container named "key-table", in which a YANG list named "security-association-entry" is defined. The entries in the "security-association-entry" YANG list represents the rows that correspond to the cryptographic keys in [RFC7210] key table.

The base model further defines each "security-association-entry" to
consist of attributes that are common across all protocols:

- admin-key-name
- key
- interfaces
- send-lifetime-start
- send-lifetime-end
- accept-lifetime-start
- accept-lifetime-end

Additionally, the base model also defines two attributes, "peers" and "protocol-specific-info", as placeholders left for each protocol to define, as prescribed by [RFC7210].

```
module: ietf-key-table
   +--rw key-table
      +--rw security-association-entry* [admin-key-name]
      |    +--rw admin-key-name            string
      |    +--rw peers
      +--rw interfaces
         +--rw (interface-options)
            +--:(all-interfaces)
            |    +--rw all?         empty
            +--:(interface-list)
               +--rw interface*   if:interface-ref
      +--rw protocol                  identityref
      +--rw protocol-specific-info
      |    +--rw key                       yang:hex-string
      |    +--rw send-lifetime-start       lifetime-type
      |    +--rw send-lifetime-end         lifetime-type
      |    +--rw accept-lifetime-start     lifetime-type
      |    +--rw accept-lifetime-end       lifetime-type
```

### 2.2. Protocol Customization

Besides the attributes defined in the base model, for each row in the key table, [RFC7210] also defines the following attributes for which the format and range of valid values are protocol-specific.

- local key name
- peer key name
After a routing protocol augments the base model to incorporate the attributes above, the result is a key table with all the necessary attributes for routing protocol authentication, as shown in the key table below with RSVP customization.

module: ietf-key-table
  +--rw key-table
    +--rw security-association-entry* [admin-key-name]
      +--rw admin-key-name            string
    +--rw interfaces
      +--rw (interface-options)
        +--:(all-interfaces)
          +--rw all?         empty
        +--:(interface-list)
          +--rw interface*   if:interface-ref
    +--rw protocol                  identityref
    +--rw protocol-specific-info
    +--rw key                       yang:hex-string
    +--rw send-lifetime-start       lifetime-type
    +--rw send-lifetime-end         lifetime-type
    +--rw accept-lifetime-start     lifetime-type
    +--rw accept-lifetime-end       lifetime-type
    +--rw peers

augment /keytable:key-table/keytable:security-association-entry + /keytable:peers:
  +--rw rsvp-security-association?   leafref

augment /keytable:key-table/keytable:security-association-entry:
  +--rw kdf?         key-derivation-function-type
  +--rw alg-id?      cryptographic-algorithm-type
  +--rw direction?   enumeration

module: example-rsvp-key-table
  +--rw example-rsvp-key-table
    +--rw rsvp-security-association-entry* [name]
      +--rw name             string
      +--rw rsvp-local-key-name?   uint64
      +--rw rsvp-peer-key-name?    uint64
3. Key-chain vs. Key-table Comparison

The key-chain YANG model also proposes a YANG model for key management. This section compares the key-chain model and the key-table model proposed in this document.

3.1. Organization

The key-chain YANG model groups several keys into a single key chain. It is the key chain that is referenced and applied by routing protocols. Consequently, the key-chain YANG model defines a hierarchical database, which consists of a top-level key-chain database, and each key-chain database consists of the actual keys that are used by a protocol. A routing protocol that requires encryption or authentication must reference a key-chain instead of the individual keys.

In contrast, [RFC7210] defines a single flat database of keys and their attributes. [RFC7210] does not require that an implementation of key management explicitly group a set of keys into a separate entity that routing protocols reference and use. Consequently, the key-table base model defined in this document presents a flat view of the key database.

For routing protocol customization, the key-table base model can also be adapted to hierarchical key management as described in the key-chain YANG model. Section 5 provides an example of adapting a hierarchical key management model into the key-table model.

3.2. Missing Attributes

The key-chain YANG model defines only a subset of key attributes defined in [RFC7210]. Consequently, the key-chain YANG model can only support specific types of deployments requiring authentication. A list of key attributes defined in [RFC7210] and in this document, but not defined in [key-chain], are as follows:

- Peer key name
- Interfaces
- Protocol
- Key derivation function
- Direction
In addition to the list above, [key-chain] also does not define attributes that [RFC7210] defined but left the detailed definitions to individual routing protocols. Similar to [RFC7210], this document defines YANG constructs for these attributes and intends for routing protocols to provided the details. The attributes in question are as follows:

- Peers
- ProtocolSpecificInfo

4. YANG Module

```<CODE BEGINS> file "ietf-key-table@2015-08-28.yang"

module ietf-key-table {

}
}

5. Usage

A routing protocol that requires cryptographic key authentication
should customize the key table base model such that the resulting
YANG modules describe all the necessary attributes and also the valid
values of these attributes.

An an example, the customized example-ospf-key-table YANG module
below augments the key table base model to include "key-derivation-
function", "cryptographic-algorithm", and "direction" attributes, as
well as specifying the valid values for those attributes. The module
below further uses the "peers" field in the base key table to
reference keys that are organized into key chains as expected by the
existing OSPF YANG module [I-D.ospf-yang].

module example-ospf-key-table {
    namespace "http://www.example.com/example-ospf-key-table";
    prefix "ospf-keytable";

    import ietf-key-table {
        prefix "keytable";
    }

    import ietf-routing {
        prefix "rt";
    }

    organization
        "Ericsson";

Abstract

This draft defines a NETCONF server configuration data model and a RESTCONF server configuration data model. These data models enable configuration of the NETCONF and RESTCONF services themselves, including which transports are supported, what ports the servers listen on, call-home parameters, client authentication, and related parameters.

Editorial Note (To be removed by RFC Editor)

This draft contains many placeholder values that need to be replaced with finalized values at the time of publication. This note summarizes all of the substitutions that are needed. Please note that no other RFC Editor instructions are specified anywhere else in this document.

This document contains references to other drafts in progress, both in the Normative References section, as well as in body text throughout. Please update the following references to reflect their final RFC assignments:

- draft-ietf-netconf-restconf
- draft-ietf-netconf-call-home

Artwork in this document contains shorthand references to drafts in progress. Please apply the following replacements:

- "VVVV" --> the assigned RFC value for this draft
- "XXXX" --> the assigned RFC value for draft-ietf-netconf-restconf
- "YYYY" --> the assigned RFC value for draft-ietf-netconf-call-home

Artwork in this document contains placeholder values for ports pending IANA assignment from "draft-ietf-netconf-call-home". Please apply the following replacements:
- "7777" --> the assigned port value for "netconf-ch-ssh"
- "8888" --> the assigned port value for "netconf-ch-tls"
- "9999" --> the assigned port value for "restconf-ch-tls"

Artwork in this document contains placeholder values for the date of publication of this draft. Please apply the following replacement:
- "2015-10-09" --> the publication date of this draft

The following two Appendix sections are to be removed prior to publication:
- Appendix B. Change Log
- Appendix C. Open Issues

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 11, 2016.

1. Introduction

This draft defines a NETCONF [RFC6241] server configuration data model and a RESTCONF [draft-ietf-netconf-restconf] server configuration data model. These data models enable configuration of the NETCONF and RESTCONF services themselves, including which transports are supported, what ports the servers listen on, call-home parameters, client authentication, and related parameters.

1.1. Terminology

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

1.2. Tree Diagrams

A simplified graphical representation of the data models is used in this document. The meaning of the symbols in these diagrams is as follows:

- Brackets "[" and "]" enclose list keys.
- Braces "{" and "}" enclose feature names, and indicate that the named feature must be present for the subtree to be present.
- Abbreviations before data node names: "rw" means configuration (read-write) and "ro" state data (read-only).
- Symbols after data node names: "?" means an optional node, "!" means a presence container, and "*" denotes a list and leaf-list.
2. Objectives

The primary purpose of the YANG modules defined herein is to enable the configuration of the NETCONF and RESTCONF services on a network element. This scope includes the following objectives:

2.1. Support all NETCONF and RESTCONF transports

The YANG module should support all current NETCONF and RESTCONF transports, namely NETCONF over SSH [RFC6242], NETCONF over TLS [RFC7589], and RESTCONF over TLS [draft-ietf-netconf-restconf], and to be extensible to support future transports as necessary.

Because implementations may not support all transports, the module should use YANG "feature" statements so that implementations can accurately advertise which transports are supported.

2.2. Enable each transport to select which keys to use

Servers may have a multiplicity of host-keys or server-certificates from which subsets may be selected for specific uses. For instance, a NETCONF server may want to use one set of SSH host-keys when listening on port 830, and a different set of SSH host-keys when calling home. The data models provided herein should enable configuration of which keys to use on a per-use basis.

2.3. Support authenticating NETCONF/RESTCONF clients certificates

When a certificate is used to authenticate a NETCONF or RESTCONF client, there is a need to configure the server to know how to authenticate the certificates. The server should be able to authenticate the client's certificate either by using path-validation to a configured trust anchor or by matching the client-certificate to one previously configured.

2.4. Support mapping authenticated NETCONF/RESTCONF client certificates to usernames

When a client certificate is used for TLS client authentication, the NETCONF/RESTCONF server must be able to derive a username from the authenticated certificate. Thus the modules defined herein should enable this mapping to be configured.
2.5. Support both listening for connections and call home

The NETCONF and RESTCONF protocols were originally defined as having the server opening a port to listen for client connections. More recently the NETCONF working group defined support for call-home ([draft-ietf-netconf-call-home]), enabling the server to initiate the connection to the client, for both the NETCONF and RESTCONF protocols. Thus the modules defined herein should enable configuration for both listening for connections and calling home. Because implementations may not support both listening for connections and calling home, YANG "feature" statements should be used so that implementation can accurately advertise the connection types it supports.

2.6. For Call Home connections

The following objectives only pertain to call home connections.

2.6.1. Support more than one NETCONF/RESTCONF client

A NETCONF/RESTCONF server may be managed by more than one NETCONF/RESTCONF client. For instance, a deployment may have one client for provisioning and another for fault monitoring. Therefore, when it is desired for a server to initiate call home connections, it should be able to do so to more than one client.

2.6.2. Support NETCONF/RESTCONF clients having more than one endpoint

An NETCONF/RESTCONF client managing a NETCONF/RESTCONF server may implement a high-availability strategy employing a multiplicity of active and/or passive endpoint. Therefore, when it is desired for a server to initiate call home connections, it should be able to connect to any of the client’s endpoints.

2.6.3. Support a reconnection strategy

Assuming a NETCONF/RESTCONF client has more than one endpoint, then it becomes necessary to configure how a NETCONF/RESTCONF server should reconnect to the client should it lose its connection to one the client’s endpoints. For instance, the NETCONF/RESTCONF server may start with first endpoint defined in a user-ordered list of endpoints or with the last endpoints it was connected to.

2.6.4. Support both persistent and periodic connections

NETCONF/RESTCONF clients may vary greatly on how frequently they need to interact with a NETCONF/RESTCONF server, how responsive interactions need to be, and how many simultaneous connections they
can support. Some clients may need a persistent connection to
erservers to optimize real-time interactions, while others prefer
periodic interactions in order to minimize resource requirements.
Therefore, when it is necessary for server to initiate connections,
it should be configurable if the connection is persistent or
periodic.

2.6.5. Reconnection strategy for periodic connections

The reconnection strategy should apply to both persistent and
periodic connections. How it applies to periodic connections becomes
clear when considering that a periodic "connection" is a logical
connection to a single server. That is, the periods of
unconnectedness are intentional as opposed to due to external
reasons. A periodic "connection" should always reconnect to the same
server until it is no longer able to, at which time the reconnection
strategy guides how to connect to another server.

2.6.6. Keep-alives for persistent connections

If a persistent connection is desired, it is the responsibility of
the connection initiator to actively test the "aliveness" of the
connection. The connection initiator must immediately work to
reestablish a persistent connection as soon as the connection is
lost. How often the connection should be tested is driven by
NETCONF/RESTCONF client requirements, and therefore keep-alive
settings should be configurable on a per-client basis.

2.6.7. Customizations for periodic connections

If a periodic connection is desired, it is necessary for the NETCONF/
RESTCONF server to know how often it should connect. This frequency
determines the maximum amount of time a NETCONF/RESTCONF client may
have to wait to send data to a server. A server may connect to a
client before this interval expires if desired (e.g., to send data to
a client).

3. High-Level Design

The solution presented in this document defines a configurable
keychain object, reusable groupings for SSH and TLS based servers,
and, finally, the configurable NETCONF and RESTCONF server objects,
which are the primary purpose for this draft. Each of these are
defined in a distinct YANG module, thus a total of five YANG modules
are defined in this document. The relationship between these five
YANG modules is illustrated by the tree diagram below.
4. Solution

Each of the following five sections relate to one of the YANG modules depicted by the figure above.

4.1. The Keychain Model

The keychain model depicted in this section provides a configurable object having the following characteristics:

- A semi-configurable list of private keys, each with one or more associated certificates. Though private keys can only be created via an RPC (see bullet #3 below), the entries of the list may be renamed and have certificates associated with them after creation.

- A configurable list of lists of trust anchor certificates. This enables the server to have use-specific trust anchors. For instance, one list of trust anchors might be used to authenticate management connections (e.g., client certificate-based authentication for NETCONF or RESTCONF connections), and a different list of trust anchors might be used for when connecting to a specific Internet-based service (e.g., a zero touch bootstrap server).

- An RPC to request the server to generate a new private key using the specified algorithm and key length.
o An RPC to generate a certificate signing request for an existing private key, a passed subject, and an optional attributes. The signed certificate returned from an external certificate authority (CA) can be set using a standard configuration change request (e.g., <edit-config>).

4.1.1. Tree Diagram

```
module: ietf-keychain
 +--rw keychain
     +--rw private-keys
         +--rw private-key* [name]
             +--rw name                                    string
             +--ro algorithm?                              enumeration
             +--ro key-length?                             uint32
             +--ro public-key?                             string
             +--rw certificates
                 +--rw certificate* [name]
                     +--rw name     string
                     +--rw chain?   binary
                 +--x generate-certificate-signing-request
                     +--w input
                         +--w subject       binary
                         +--w attributes?   binary
                     +--ro output
                         +--ro certificate-signing-request    binary
             +--x generate-private-key
                 +--w input
                     +--w name          string
                     +--w algorithm     enumeration
                     +--w key-length?   uint32
             +--rw trusted-certificates* [name]
                 +--rw name                   string
                 +--rw description?           string
                 +--rw trusted-certificate* [name]
                     +--rw name                   string
                     +--rw certificate?         binary
```

4.1.2. Example Usage

The following example illustrates the "generate-private-key" RPC in use with the RESTCONF protocol and JSON encoding.
The following example illustrates the action statement "generate-certificate-signing-request" action in use with the NETCONF protocol.
The following example illustrates what a fully configured keychain object might look like. The private-key shown below is consistent with the generate-private-key and generate-certificate-signing-request examples above. This example also assumes that the resulting CA-signed certificate has been configured back onto the server. Lastly, this example shows that three lists of trusted certificates having been configured.

```
<keychain xmlns="urn:ietf:params:xml:ns:yang:ietf-keychain">
  ...
</keychain>
```

<CODE ENDS>

4.2. The SSH Server Model

The SSH Server model presented in this section presents two YANG
groupings, one for a server that opens a socket to accept TCP
connections on, and another for a server that has had the TCP
connection opened for it already (e.g., inetd).

The SSH Server model (like the TLS Server model presented below) is
provided as a grouping so that it can be used in different contexts.
For instance, the NETCONF Server model presented in Section 4.4 uses
one grouping to configure a NETCONF server listening for connections
and the other grouping to configure NETCONF call home.

A shared characteristic between both groupings is the ability to
configure which host key is presented to clients, the private key for
which is held in the keychain configuration presented before. Another shared characteristic is the ability to configure which trusted CA or client certificates the server should be used to authenticate clients when using X.509 based client certificates [RFC6187].

4.2.1. Tree Diagram

The following tree diagram represents the data model for the grouping used to configure an SSH server to listen for TCP connections. The tree diagram for the other grouping is not provided, but it is the same except without the "address" and "port" fields.

NOTE: the diagram below shows "listening-ssh-server" as a YANG container (not a grouping). This temporary container was created only to enable the 'pyang' tool to output the tree diagram, as groupings by themselves have no protocol accessible nodes, and hence 'pyang' would output an empty tree diagram.

module: ietf-ssh-server
   +--rw listening-ssh-server
     +--rw address? inet:ip-address
     +--rw port inet:port-number
     +--rw host-keys
       +--rw host-key* [name]
         +--rw name string
         +--rw (type)?
           +--:(public-key)
             |    +--rw public-key? -> /kc:keychain/private-keys/private-key/name
           +--:(certificate)
             |    +--rw certificate? -> /kc:keychain/private-keys/private-key/certificates/certificate/name {ssh-x509-certs}
     +--rw client-cert-auth {ssh-x509-certs}?
     +--rw trusted-ca-certs? -> /kc:keychain/trusted-certificates/name
     +--rw trusted-client-certs? -> /kc:keychain/trusted-certificates/name

4.2.2. Example Usage

This section shows how it would appear if the temporary listening-ssh-server container just mentioned above were populated with some data. This example is consistent with the examples presented earlier in this document.
<listening-ssh-server
    xmlns="urn:ietf:params:xml:ns:yang:ietf-ssh-server">
    <port>830</port>
    <host-keys>
        <host-key>
            <name>deployment-specific-certificate</name>
            <certificate>ex-key-sect571r1-cert</certificate>
        </host-key>
    </host-keys>
    <client-cert-auth>
        <trusted-ca-certs>
            deployment-specific-ca-certs
        </trusted-ca-certs>
        <trusted-client-certs>
            explicitly-trusted-client-certs
        </trusted-client-certs>
    </client-cert-auth>
</listening-ssh-server>

}

4.3. The TLS Server Model

The TLS Server model presented in this section presents two YANG groupings, one for a server that opens a socket to accept TCP connections on, and another for a server that has had the TCP connection opened for it already (e.g., inetd).

The TLS Server model (like the SSH Server model presented above) is provided as a grouping so that it can be used in different contexts. For instance, the NETCONF Server model presented in Section 4.4 uses one grouping to configure a NETCONF server listening for connections and the other grouping to configure NETCONF call home.

A shared characteristic between both groupings is the ability to configure which server certificate is presented to clients, the private key for which is held in the keychain model presented in Section 4.1. Another shared characteristic is the ability to configure which trusted CA or client certificates the server should be used to authenticate clients.

4.3.1. Tree Diagram

The following tree diagram represents the data model for the grouping used to configure an TLS server to listen for TCP connections. The tree diagram for the other grouping is not provided, but it is the same except without the "address" and "port" fields.

NOTE: the diagram below shows "listening-ssh-server" as a YANG container (not a grouping). This temporary container was created only to enable the 'pyang' tool to output the tree diagram, as groupings by themselves have no protocol accessible nodes, and hence 'pyang' would output an empty tree diagram.

    uses listening-tls-server-grouping;
}

4.4. The NETCONF Server Model

The NETCONF Server model presented in this section supports servers both listening for connections to accept as well as initiating call-home connections. This model also supports both the SSH and TLS transport protocols, using the SSH Server and TLS Server groupings presented in Section 4.2 and Section 4.3 respectively. All private keys and trusted certificates are held in the keychain model presented in Section 4.1. YANG feature statements are used to enable implementations to advertise which parts of the model the NETCONF server supports.

4.4.1. Tree Diagram

The following tree diagram uses line-wrapping in order to comply with xml2rfc validation. This is annoying as I find that drafts (even txt drafts) look just fine with long lines - maybe xml2rfc should remove this warning? - or pyang could have an option to suppress printing leafref paths?

```yang
module: ietf-netconf-server
  +--rw netconf-server
    +--rw session-options
      |  +--rw hello-timeout? uint16
      +--rw listen { (ssh-listen or tls-listen) }?
        +--rw max-sessions? uint16
        +--rw idle-timeout? uint16
        +--rw endpoint* [name]
          +--rw name string
          +--rw (transport)

4.4.2. Example Usage

Configuring a NETCONF Server to listen for NETCONF client connections using both the SSH and TLS transport protocols, as well as configuring call-home to two NETCONF clients, one using SSH and the other using TLS.
This example is consistent with other examples presented in this document.

<netconf-server
    xmlns="urn:ietf:params:xml:ns:yang:ietf-netconf-server">
    <listen>
        <!-- listening for SSH connections -->
        <endpoint>
            <name>netconf/ssh</name>
            <ssh>
                <address>11.22.33.44</address>
                <host-keys>
                    <host-key>
                        <public-key>my-rsa-key</public-key>
                    </host-key>
                    <host-key>
                        <certificate>TPM key</certificate>
                    </host-key>
                </host-keys>
                <client-cert-auth>
                    <trusted-ca-certs>
                        deployment-specific-ca-certs
                    </trusted-ca-certs>
                    <trusted-client-certs>
                        explicitly-trusted-client-certs
                    </trusted-client-certs>
                </client-cert-auth>
            </ssh>
        </endpoint>
        <!-- listening for TLS connections -->
        <endpoint>
            <name>netconf/tls</name>
            <tls>
                <address>11.22.33.44</address>
                <certificates>
                    <certificate>ex-key-sect571r1-cert</certificate>
                </certificates>
                <client-auth>
                    <trusted-ca-certs>
                        deployment-specific-ca-certs
                    </trusted-ca-certs>

4.5. The RESTCONF Server Model

The RESTCONF Server model presented in this section supports servers both listening for connections to accept as well as initiating call-home connections. This model supports the TLS transport only, as RESTCONF only supports HTTPS, using the TLS Server groupings presented in Section 4.3. All private keys and trusted certificates are held in the keychain model presented in Section 4.1. YANG feature statements are used to enable implementations to advertise which parts of the model the RESTCONF server supports.

4.5.1. Tree Diagram

The following tree diagram uses line-wrapping in order to comply with xml2rfc validation. This is annoying as I find that drafts (even txt drafts) look just fine with long lines – maybe xml2rfc should remove this warning? – or pyang could have an option to suppress printing leafref paths?

```
module: ietf-restconf-server
  +--rw restconf-server

Watsen & Schoenwaelder Expires April 11, 2016 [Page 47]```
++rw listen {tls-listen}?

4.5.3. YANG Model

This YANG module imports YANG types from [RFC6991] and [RFC7407].

<CODE BEGINS> file "ietf-restconf-server@2015-10-09.yang"

module ietf-restconf-server {
    yang-version 1.1;

    namespace "urn:ietf:params:xml:ns:yang:ietf-restconf-server";
    prefix "rcserver";

    //import ietf-netconf-acm {
    //  prefix nacm;                     // RFC 6536
    //}
    import ietf-inet-types {           // RFC 6991
        prefix inet;
    }
    import ietf-x509-cert-to-name {    // RFC 7407
        prefix x509c2n;
    }
    import ietf-tls-server {           // RFC VVVV
        prefix ts;

<CODE ENDS>

5. Security Considerations

This section needs to be filled in...

6. IANA Considerations

This document registers two URIs in the IETF XML registry [RFC2119]. Following the format in [RFC3688], the following registrations are requested:

Registrant Contact: The NETCONF WG of the IETF.
XML: N/A, the requested URI is an XML namespace.

Registrant Contact: The NETCONF WG of the IETF.
XML: N/A, the requested URI is an XML namespace.

This document registers two YANG modules in the YANG Module Names registry [RFC6020]. Following the format in [RFC6020], the following registrations are requested:
7. Other Considerations

The YANG modules define herein do not themselves support virtual routing and forwarding (VRF). It is expected that external modules will augment in VRF designations when needed.

8. Acknowledgements

The authors would like to thank for following for lively discussions on list and in the halls (ordered by last name): Andy Bierman, Martin Bjorklund, Benoit Claise, Mehmet Ersue, David Lamparter, Alan Luchuk, Ladislav Lhotka, Radek Krejci, Tom Petch, Phil Shafer, and Bert Wijnen.

Juergen Schoenwaelder and was partly funded by Flamingo, a Network of Excellence project (ICT-318488) supported by the European Commission under its Seventh Framework Programme.

9. References
9.1.  Normative References

9.2.  Informative References

Appendix A. Change Log

A.1. 00 to 01

- Restructured document so it flows better
- Added trusted-ca-certs and trusted-client-certs objects into the ietf-system-tls-auth module

A.2. 01 to 02

- Removed the "one-to-many" construct
- Removed "address" as a key field
- Removed "network-manager" terminology
- Moved open issues to github issues
- Brought TLS client auth back into model

A.3. 02 to 03

- Fixed tree diagrams and surrounding text

A.4. 03 to 04

- Reduced the number of grouping statements
- Removed psk-maps and associated feature statements
- Added ability for listen/call-home instances to specify which host-keys/certificates (of all listed) to use
- Clarified that last-connected should span reboots
- Added missing "objectives" for selecting which keys to use, authenticating client-certificates, and mapping authenticated client-certificates to usernames
- Clarified indirect client certificate authentication
- Added keep-alive configuration for listen connections
- Added global-level NETCONF session parameters
A.5. 04 to 05
- Removed all refs to the old ietf-system-tls-auth module
- Removed YANG 1.1 style if-feature statements (loss some expressiveness)
- Removed the read-only (config false) lists of SSH host-keys and TLS certs
- Added an if-feature around session-options container
- Added ability to configure trust-anchors for SSH X.509 client certs
- Now imports by revision, per best practice
- Added support for RESTCONF server
- Added RFC Editor instructions

A.6. 05 to 06
- Removed feature statement on the session-options container (issue #21).
- Added NACM statements to YANG modules for sensitive nodes (issue #24).
- Fixed default RESTCONF server port value to be 443 (issue #26).
- Added client-cert-auth subtree to ietf-restconf-server module (issue #27).
- Updated draft-ietf-netmod-snmp-cfg reference to RFC 7407 (issue #28).
- Added description statements for groupings (issue #29).
- Added description for braces to tree diagram section (issue #30).
- Renamed feature from "rfc6187" to "ssh-x509-certs" (issue #31).

A.7. 06 to 07
- Replaced "application" with "NETCONF/RESTCONF client" (issue #32).
- Reverted back to YANG 1.1 if-feature statements (issue #34).
- Removed import by revisions (issue #36).
- Removed groupings only used once (issue #37).
- Removed upper-bound on hello-timeout, idle-timeout, and max-
  sessions (issue #38).
- Clarified that when no listen address is configured, the NETCONF/
  RESTCONF server will listen on all addresses (issue #41).
- Update keep-alive reference to new section in Call Home draft
  (issue #42).
- Modified connection-type/persistent/keep-alives/interval-secs
  default value, removed the connection-type/periodic/linger-secs
  node, and also removed the reconnect-strategy/interval-secs node
  (issue #43).
- Clarified how last-connected reconnection type should work across
  reboots (issue #44).
- Clarified how DNS-expanded hostnames should be processed (issue
  #45).
- Removed text on how to implement keep-alives (now in the call-home
  draft) and removed the keep-alive configuration for listen
  connections (issue #46).
- Clarified text for .../periodic-connection/timeout-mins (issue
  #47).
- Fixed description on the "trusted-ca-certs" leaf-list (issue #48).
- Added optional keychain-based solution in appendix A (issue #49).
- Fixed description text for the interval-secs leaf (issue #50).
- moved idle-time into the listen, persistent, and periodic subtrees
  (issue #51).
- put presence statements on containers where it makes sense (issue
  #53).

A.8. 07 to 08

- Per WG consensus, replaced body with the keychain-based approach
described in -07’s Appendix.
Added a lot of introductory text, improved examples, and what not.

Appendix B. Open Issues
