Generic YANG Data Model for Connection Oriented Operations, Administration, and Maintenance (OAM) protocols
draft-ietf-lime-yang-oam-model-07

Abstract

This document presents a base YANG Data model for connection oriented OAM protocols. It provides a technology-independent abstraction of key OAM constructs for such protocols. The model presented here can be extended to include technology specific details. This guarantees uniformity in the management of OAM protocols and provides support for nested OAM workflows (i.e., performing OAM functions at different levels through a unified interface)

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 9, 2017.

1. Introduction

Operations, Administration, and Maintenance (OAM) are important networking functions that allow operators to:

1. Monitor networks connections (Connectivity Verification, Continuity Check).
2. Troubleshoot failures (Fault verification and localization).
3. Monitor Performance

An overview of OAM tools is presented in [RFC7276][RFC7276]. Over the years, many technologies have developed similar tools for fault and performance management.

[IEEE802.1Q] Connectivity Fault Management is a well-established OAM standard that is widely adopted for Ethernet networks. ITU-T [G.8013][G.8013], MEF Service OAM, MPLS-TP [RFC6371], TRILL [RFC7455][RFC7455] all define OAM mechanisms based on the manageability frame work of [IEEE802.1Q] [IEEE802.1Q]CFM.

Given the wide adoption of the underlying OAM concepts defined in [IEEE802.1Q][IEEE802.1Q] CFM, it is a reasonable choice to develop the unified management framework for connection oriented OAM based on those concepts. In this document, we take the [IEEE802.1Q][IEEE802.1Q] CFM model and extend it to a technology independent framework and define the corresponding YANG model accordingly. The YANG model presented in this document is the base model for connection oriented OAM protocols and supports generic continuity check, connectivity verification (Loopback) and path discovery (traceroute). The generic YANG model for connection oriented OAM is designed to be extensible to other connection oriented technologies. Technology dependent nodes and remote process call (RPC) commands are defined in technology specific YANG models, which use and extend the base model defined here. As an example, VXLAN uses source UDP port number for flow entropy, while TRILL uses either MAC addresses, the VLAN tag or fine grain label, and/or IP addresses for flow entropy in the hashing for multipath selection. To capture this variation, corresponding YANG models would define the applicable structures as augmentation to the generic base model presented here. This accomplishes three goals: First it keeps each YANG model smaller and more manageable. Second, it allows independent development of corresponding YANG models. Third, implementations can limit support to only the applicable set of YANG models. (e.g. TRILL RBridge may only need to implement Generic model and the TRILL YANG model).
All implementations that follow the YANG framework presented in this document MUST implement the generic connection oriented YANG model presented here.

The YANG data model presented in this document is generated at the management layer. Encapsulations and state machines may differ according to each OAM protocol. A user who wishes to issue a Continuity Check command or a Loopback or initiate a performance monitoring session can do so in the same manner regardless of the underlying protocol or technology or specific vendor implementation.

As an example, consider a scenario where Loopback from device A to Device B fails. Between device A and B there are IEEE 802.1 bridges a, b and c. Let’s assume a,b and c are using [IEEE802.1Q] CFM. Upon detecting the Loopback failures, a user may decide to drill down to the lower level at different segments of the path and issue the corresponding fault verification (LBM) and fault isolation (LTM) tools, using the same API. This ability to drill down to a lower layer of the protocol stack at a specific segment within a path for fault localization and troubleshooting is referred to as "nested OAM workflow". It is a useful concept that leads to efficient network troubleshooting and maintenance workflows. The connection oriented OAM YANG model presented in this document facilitates that without needing changes to the underlying protocols.

2. Conventions used in this document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119]. Lower case uses of these words are not to be interpreted as carrying [RFC2119] significance.

The following notations are used within the data tree and carry the meaning as below.

Each node is printed as:
<status> <flags> <name> <opts> <type>

<status> is one of:
   + for current
   x for deprecated
   o for obsolete

<flags> is one of:
   rw for configuration data
   ro for non-configuration data
   -x for rpcs
   -n for notifications

 название только когда в строчках.
<name> is the name of the node
If the node is augmented into the tree from another module, its name is printed as <prefix>:<name>.

<opts> is one of:
   ? for an optional leaf or choice
   ! for a presence container
   * for a leaf-list or list
   [<keys>] for a list’s keys
   (choice)/:(case) Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (":")
<type> is the name of the type for leafs and leaf-lists

In this document, these words will appear with that interpretation only when in ALL CAPS.

2.1. Terminology

CCM   - Continuity Check Message [IEEE802.1Q].
ECMP  - Equal Cost Multipath.
LBM   - Loopback Message [IEEE802.1Q].
MP    - Maintenance Point [IEEE802.1Q].
MEP   - Maintenance End Point [RFC7174] (Maintenance association End Point [IEEE802.1Q], MEG End Points [RFC6371]).
MIP - Maintenance Intermediate Point [RFC7174] (Maintenance domain Intermediate Point [IEEE802.1Q], MEG Intermediate Point [RFC6371]).

MA - Maintenance Association [IEEE802.1Q] [RFC7174].

MD - Maintenance Domain [IEEE802.1Q]

MEG - Maintenance Entity Group [RFC6371]

MTV - Multi-destination Tree Verification Message.

OAM - Operations, Administration, and Maintenance [RFC6291].

TRILL - Transparent Interconnection of Lots of Links [RFC6325].

CFM - Connectivity Fault Management [RFC7174] [IEEE802.1Q].

RPC - Remote Process Call.

CC - Continuity Check [RFC7276]. Continuity Checks are used to verify that a destination is reachable and therefore also referred to as reachability verification.

CV - Connectivity Verification [RFC7276]. Connectivity Verification are used to verify that a destination is connected. It are also referred to as path verification and used to verify not only that the two MPs are connected, but also that they are connected through the expected path, allowing detection of unexpected topology changes.

3. Architecture of Generic YANG Model for OAM

In this document we define a generic YANG model for connection oriented OAM protocols. The YANG model defined here is generic in a sense that other technologies can extend it for technology specific needs. The Generic YANG model acts as the root for other OAM YANG models. This allows users to traverse between different OAM protocols with ease through a uniform API set. This also enables a nested OAM workflow. Figure 1 depicts the relationship of different OAM YANG models to the Generic YANG Model for connection oriented OAM. The Generic YANG model for OAM provides a framework where technology-specific YANG models can inherit constructs from the base YANG models without needing to redefine them within the sub-technology.

Figure 1 depicts relationship of different YANG modules.
4. Overview of the OAM Model

In this document we adopt the concepts of the [IEEE802.1Q] CFM model and structure it such that it can be adapted to different connection oriented OAM protocols.

At the top of the Model is the Maintenance Domain. Each Maintenance Domain is associated with a Maintenance Name and a Domain Level.

Under each Maintenance Domain there is one or more Maintenance Association (MA). In TRILL this can be per Fine-Grained Label or for VPLS this can be per VPLS instance.

Under each MA, there can be two or more MEPs (Maintenance Association End Points). MEPs are addressed by their respective technology specific address identifiers. The YANG model presented here provides flexibility to accommodate different addressing schemes.

In the vertical direction orthogonal to the Maintenance Domain, presented are the commands. Those, in YANG terms, are the rpc...
commands. These rpc commands provide uniform APIs for continuity check, connectivity verification(loopback), path discovery(traceroute) and their equivalents as well as other OAM commands.

The generic YANG model defined here does not require explicit configuration of OAM entities prior to using any of the OAM tools. The OAM tools used here are limited to OAM toolset specified in section 5.1 of [RFC7276]. In order to facilitate zero-touch experience, this document defines a default mode of OAM. The default mode of OAM is referred to as the Base Mode and specifies default values for each of model parameters, such as Maintenance Domain Level, Name of the Maintenance Association, Addresses of MEPs and so on. The default values of these depend on the technology. Base Mode for TRILL is defined in [RFC7455]. Base mode for other technologies and future extensions developed in IETF will be defined in their corresponding documents.

It is important to note that, no specific enhancements are needed in the YANG model to support Base Mode. Implementations that comply with this document, by default implement the data nodes of the applicable technology. Data nodes of the Base Mode are read-only nodes.

4.1. Maintenance Domain (MD) configuration

The container "domains" is the top level container within the gen-oam module. Within the container "domains", separate list is maintained per MD. The MD list uses the key MD-name-string for indexing. MD-name-string is a leaf and derived from type string. Additional name formats as defined in [IEEE802.1Q] or other standards can be included by association of the MD-name-format with an identity-ref. MD-name-format indicates the format of the augmented MD-names. MD-name is presented as choice/case construct. Thus, it is easily augmentable by derivative work.

```
module: ietf-conn-oam
  +--rw domains
    +--rw domain* [technology MD-name-string]
      +--rw technology identityref
      +--rw MD-name-string MD-name-string
      +--rw MD-name-format? identityref
      +--rw (MD-name)?
        |   +--:(MD-name-null)
        |       +--rw MD-name-null? empty
      +--rw md-level? MD-level
```

Snippet of data hierarchy related to OAM domains
### 4.2. Maintenance Association (MA) configuration

Within a given Maintenance Domain there can be one or more Maintenance Associations (MA). MAs are represented as a list and indexed by the MA-name-string. Similar to MD-name defined previously, additional name formats can be added by augmenting the name-format identity-ref and adding applicable case statements to MA-name.

```yaml
module: ietf-conn-oam
  +-rw domains
    +-rw domain* [technology MD-name-string]
    .
    +--rw MAs
      +--rw MA* [MA-name-string]
        +-rw MA-name-string MA-name-string
        +-rw MA-name-format? identityref
        +-rw (MA-name)?
          | +-rw (MA-name-null)
          |   +-rw MA-name-null? empty
```

Snippet of data hierarchy related to Maintenance Associations (MA)

### 4.3. Maintenance Endpoint (MEP) configuration

Within a given Maintenance Association (MA), there can be one or more Maintenance End Points (MEP). MEPs are represented as a list within the data hierarchy and indexed by the key MEP-name.
4.4. rpc definitions

The rpc model facilitates issuing commands to a NETCONF server (in this case to the device that need to execute the OAM command) and obtain a response. rpc model defined here abstracts OAM specific commands in a technology independent manner.

There are several rpc commands defined for the purpose of OAM. In this section we present a snippet of the continuity check command for illustration purposes. Please refer to Section 4 for the complete data hierarchy and Section 5 for the YANG model.

4.5. notifications

Notification is sent on defect condition and defect clears with Maintenance Domain Name, MA Name, defect-type (The currently active defects), generating-mepid, and defect-message to indicate more details.

4.6. monitor statistics

Grouping for monitoring statistics is to be used by Yang modules which Augment Yang to provide statistics due to pro-active OAM like CCM Messages. For example CCM Transmit, CCM Receive, CCM Errors, etc.

4.7. OAM data hierarchy

The complete data hierarchy related to the connection oriented OAM YANG model is presented below.

module: ietf-conn-oam
  +--rw domains
  |  +--rw domain* [technology MD-name-string]

YANG module of OAM

<CODE ENDS>

6. Base Mode

The Base Mode defines default configuration that MUST be present in
the devices that comply with this document. Base Mode allows users
to have "zero-touch" experience. Several parameters require
technology specific definition.

6.1. MEP Address

In the Base Mode of operation, the MEP Address is by default the IP
address of the interface on which the MEP is located.
6.2. MEP ID for Base Mode

In the Base Mode of operation, each device creates a single UP MEP associated with a virtual OAM port with no physical layer (NULL PHY). The MEPID associated with this MEP is zero (0). The choice of MEP-ID zero is explained below.

MEPID is 2 octet field by default. It is never used on the wire except when using CCM. It is important to have method that can derive MEP ID of base mode in an automatic manner with no user intervention. IP address cannot be directly used for this purpose as the MEP ID is much smaller field. For Base Mode of operation we propose to use MEP ID zero (0) as the default MEP-ID.

CCM packet use MEP-ID on the payload. CCM MUST NOT be used in the Base Mode. Hence CCM MUST be disabled on the Maintenance Association of the Base Mode.

If CCM is required, users MUST configure a separate Maintenance association and assign unique value for the corresponding MEP IDs.

[IEEE802.1Q] CFM defines MEP ID as an unsigned integer in the range 1 to 8191. In this document we propose to extend the range to 0 to 65535. Value 0 is reserved for MEP ID of Base Mode operation and MUST NOT be used for other purposes.

6.3. Maintenance Association

MAID [IEEE802.1Q] has a flexible format and includes two parts: Maintenance Domain Name and Short MA name. In the Based Mode of operation, the value of the Maintenance Domain Name must be the character string "GenericBaseMode" (excluding the quotes "). In Base Mode operation Short MA Name format is set to 2-octet integer format (value 3 in Short MA Format field [IEEE802.1Q]) and Short MA name set to 65532 (0xFFFC).

7. connection-oriented oam yang model applicability

ietf-conn-oam model defined in this document provides technology-independent abstraction of key OAM constructs for connection oriented protocols. This model can be further extended to include technology specific details, e.g., adding new data nodes with technology specific functions and parameters into proper anchor points of the base model, so as to develop a technology-specific connection-oriented OAM model.

This section demonstrates the usability of the connection-oriented YANG OAM data model to various connection-oriented OAM technologies,
e.g., TRILL and MPLS-TP. Note that, in this section, we only present several snippets of technology-specific model extensions for illustrative purposes. The complete model extensions should be worked on in respective protocol working groups.

7.1. Generic YANG Model extension for TRILL OAM

The TRILL YANG module is augmenting connection oriented OAM module for both configuration and RPC commands.

The TRILL YANG module requires the base TRILL module ([I-D.ietf-trill-yang]) to be supported as there is a strong relationship between those modules.

The configuration extensions for connection oriented OAM include MD configuration extension, Technology type extension, MA configuration extension, Connectivity-Context Extension, MEP Configuration Extension, ECMP extension. In the RPC extension, the continuity-check and path-discovery RPC are extended with TRILL specific.

7.1.1. MD Configuration Extension

MD level configuration parameters are management information which can be inherited in the TRILL OAM model and set by connection oriented base model as default values. For example domain name can be set to area-ID in the TRILL OAM case. In addition, at the Maintenance Domain level, domain data node at root level can be augmented with technology type.

Note that MD level configuration parameters provides context information for management system to correlate faults, defects, network failures with location information, which helps quickly identify root causes of network failures.

7.1.1.1. Technology Type Extension

No TRILL technology type has been defined in the connection oriented base model. Therefore a technology type extension is required in the TRILL OAM model. The technology type "trill" is defined as an identity that augments the base "technology-types" defined in the connection oriented base model:

    identity trill{
      base goam:technology-types;
      description "trill type";
    }
7.1.2. MA Configuration Extension

MA level configuration parameters are management information which can be inherited in the TRILL OAM model and set by connection oriented base model as default values. In addition, at the Maintenance Association (MA) level, MA data node at the second level can be augmented with connectivity-context extension.

Note that MA level configuration parameters provides context information for management system to correlate faults, defects, network failures with location information, which helps quickly identify root causes of network failures.

7.1.2.1. Connectivity-Context Extension

In TRILL OAM, one example of connectivity-context is either a 12 bit VLAN ID or a 24 bit Fine Grain Label. The connection oriented base model defines a placeholder for context-id. This allows other technologies to easily augment that to include technology specific extensions. The snippet below depicts an example of augmenting connectivity-context to include either VLAN ID or Fine Grain Label.

```
augment /goam:domains/goam:domain/goam:MAs
  /goam:MA /goam:connectivity-context:
    +--:(connectivity-context-vlan)
      |   +--rw connectivity-context-vlan?   vlan
    +--:(connectivity-context-fgl)
      +--rw connectivity-context-fgl?    fgl
```

7.1.3. MEP Configuration Extension

The MEP configuration definition in the connection oriented base model already supports configuring the interface of MEP with either MAC address or IP address. In addition, the MEP address can be represented using a 2 octet RBridge Nickname in TRILL OAM. Hence, the TRILL OAM model augments the MEP configuration in base model to add a nickname case into the MEP address choice node as follows:

```
augment /goam:domains/goam:domain/goam:MAs
  /goam:MA/ goam:MEP/goam:mep-address:
    +--:( mep-address-trill)
      |   +--rw mep-address-trill?  tril-rb-nickname
```

In addition, at the Maintenance Association Endpoint (MEP) level, MEP data node at the third level can be augmented with ECMP extension.
7.1.3.1. ECMP Extension

Since TRILL supports ECMP path selection, flow-entropy in TRILL is defined as a 96 octet field in the LIME model extension for TRILL OAM. The snippet below illustrates its extension.

```
augment /goam:domains/goam:domain/goam:MAs/goam:MA/goam:MEP:
  +--rw flow-entropy-trill?  flow-entropy-trill
augment /goam:domains/goam:domain/goam:MAs/goam:MA/goam:MEP:
    /goam:session:
      +--rw flow-entropy-trill?  flow-entropy-trill
```

7.1.4. RPC extension

In the TRILL OAM YANG model, the continuity-check and path-discovery RPC commands are extended with TRILL specific requirements. The snippet below depicts an example of illustrates the TRILL OAM RPC extension.

```
augment /goam:continuity-check/goam:input:
  +--ro (out-of-band)?
    |  +--:(ipv4-address)
    |     |  +--ro ipv4-address?  inet:ipv4-address
    |  +--:(ipv6-address)
    |     |  +--ro ipv6-address?  inet:ipv6-address
    |  +--:(trill-nickname)
    |     |     +--ro trill-nickname?  tril-rb-nickname
    +--ro diagnostic-vlan?  boolean
augment /goam:continuity-check/goam:input:
  +--ro flow-entropy-trill?  flow-entropy-trill
augment /goam:continuity-check/goam:output:
  +--ro upstream-rbridge?  tril-rb-nickname
  +--ro next-hop-rbridge*  tril-rb-nickname
augment /goam:path-discovery/goam:input:
  +--ro (out-of-band)?
    |  +--:(ipv4-address)
    |     |  +--ro ipv4-address?  inet:ipv4-address
    |  +--:(ipv6-address)
    |     |  +--ro ipv6-address?  inet:ipv6-address
    |  +--:(trill-nickname)
    |     |     +--ro trill-nickname?  tril-rb-nickname
    +--ro diagnostic-vlan?  boolean
augment /goam:path-discovery/goam:input:
  +--ro flow-entropy-trill?  flow-entropy-trill
augment /goam:path-discovery/goam:output/goam:response:
  +--ro upstream-rbridge?  tril-rb-nickname
  +--ro next-hop-rbridge*  tril-rb-nickname
```
7.2. Generic YANG Model extension for MPLS-TP OAM

The MPLS-TP OAM YANG module can augment connection oriented OAM Module with some technology-specific details. And the [mpls-tp-oam-yang] presents the YANG Data model for MPLS-TP OAM.

The configuration extensions for connection oriented OAM include MD configuration extension, Technology type extension, Sub Technology Type Extension, MA configuration extension, MEP Configuration Extension.

7.2.1. MD Configuration Extension

MD level configuration parameters are management information which can be inherited in the MPLS-TP OAM model and set by LIME base model as default values. For example domain name can be set to area-ID or the provider's Autonomous System Number (ASN) [RFC6370] in the MPLS-TP OAM case. In addition, at the Maintenance Domain level, domain data node at root level can be augmented with technology type and sub-technology type.

Note that MD level configuration parameters provides context information for management system to correlate faults, defects, network failures with location information, which helps quickly identify root causes of network failures

7.2.1.1. Technology Type Extension

No MPLS-TP technology type has been defined in the connection oriented base model, hence it is required in the MPLS OAM model. The technology type "mpls-tp" is defined as an identity that augments the base "technology-types" defined in the connection oriented base model:

```
identity mpls-tp{
   base goam:technology-types;
   description
      "mpls-tp type";
}
```

7.2.1.2. Sub Technology Type Extension

In MPLS-TP, since different encapsulation types such as IP/UDP Encapsulation, PW-ACH encapsulation can be employed, the "technology-sub-type" data node is defined and added into the MPLS OAM model to further identify the encapsulation types within the MPLS-TP OAM model. Based on it, we also define a technology sub-type for IP/UDP encapsulation and PW-ACH encapsulation. Other Encapsulation types...
can be defined in the same way. The snippet below depicts an example of several encapsulation types.

```yang
identity technology-sub-type {
  description
  "certain implementations can have different
  encapsulation types such as ip/udp, pw-ach and so on.
  Instead of defining separate models for each
  encapsulation, we define a technology sub-type to
  further identify different encapsulations.
  Technology sub-type is associated at the MA level";
}

identity technology-sub-type-udp {
  base technology-sub-type;
  description
  "technology sub-type is IP/UDP encapsulation";
}

identity technology-sub-type-ach {
  base technology-sub-type;
  description
  "technology sub-type is PW-ACH encapsulation";
}
}

augment "/goam:domains/goam:domain/goam:MAs/goam:MA" {
  leaf technology-sub-type {
    type identityref {
      base technology-sub-type;
    }
  }
}

7.2.2. MA Configuration Extension

MA level configuration parameters are management information which can be inherited in the MPLS-TP OAM model and set by Connection Oriented base model as default values. Meg-Id parameter under MA data node will be selected for MPLT-TP OAM model. Therefore one example of MA Name could be MEG LSP ID or MEG Section ID or MEG PW ID[RFC6370].

Note that MA level configuration parameters provides context information for management system to correlate faults, defects, network failures with location information, which helps quickly identify root causes of network failures.
7.2.3. MEP Configuration Extension

In MPLS-TP, MEP-ID is either a variable length label value in case of G-ACH encapsulation or a 2 octet unsigned integer value in case of IP/UDP encapsulation. One example of MEP-ID is MPLS-TP LSP_MEP_ID [RFC6370]. In the connection-oriented base model, MEP-ID is defined as a choice/case node which can supports an int32 value, and the same definition can be used for MPLS-TP with no further modification. In addition, at the Maintenance Association Endpoint (MEP) level, MEP data node at the third level can be augmented with Session extension and interface extension.

8. Security Considerations

The YANG module defined in this memo is designed to be accessed via the NETCONF protocol [RFC6241] [RFC6241]. The lowest NETCONF layer is the secure transport layer and the mandatory-to-implement secure transport is SSH [RFC6242] [RFC6242]. The NETCONF access control model [RFC6536] [RFC6536] provides the means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

There are a number of data nodes defined in the YANG module which are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., <edit-config>) to these data nodes without proper protection can have a negative effect on network operations.

The vulnerable "config true" subtrees and data nodes are the following:

/goam:domains/goam:domain/
/goam:domains/goam:domain/goam:MAs/goam:MA/

Unauthorized access to any of these lists can adversely affect OAM management system handling of end-to-end OAM and coordination of OAM within underlying network layers. This may lead to inconsistent configuration, reporting, and presentation for the OAM mechanisms used to manage the network.
9. IANA Considerations

This document registers a URI in the IETF XML registry [RFC3688] [RFC3688]. Following the format in RFC 3688, the following registration is requested to be made:

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

This document registers a YANG module in the YANG Module Names registry [RFC6020].

   prefix: goam reference: RFC XXXX

10. Acknowledgments

Giles Heron came up with the idea of developing a YANG model as a way of creating a unified OAM API set (interface), work in this document is largely an inspiration of that. Alexander Clemm provided many valuable tips, comments and remarks that helped to refine the YANG model presented in this document.

Carlos Pignataro, David Ball, Mahesh Jethanandani, Benoit Claise, Ladislav Lhotka, GUBALLA JENS, Yuji Tochio, Gregory Mirsky, Huub van Helvoort, Tom Taylor, Dapeng Liu, Mishael Wexler, Adi Molkho participated and contributed to this document.

Abstract

This document presents a base YANG Data model for connection oriented OAM protocols. It provides a technology-independent abstraction of key OAM constructs for such protocols. The model presented here can be extended to include technology specific details. This guarantees uniformity in the management of OAM protocols and provides support for nested OAM workflows (i.e., performing OAM functions at different levels through a unified interface).

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on October 11, 2017.

1. Introduction

Operations, Administration, and Maintenance (OAM) are important networking functions that allow operators to:

1. Monitor networks connections (Connectivity Verification, Continuity Check).
2. Troubleshoot failures (Fault verification and localization).
3. Monitor Performance

An overview of OAM tools is presented in [RFC7276]. Over the years, many technologies have developed similar tools for fault and performance management.

[IEEE802.1ag] Connectivity Fault Management is a well-established OAM standard that is widely adopted for Ethernet networks. ITU-T [G.8013], MEF Service OAM, MPLS-TP [RFC6371], TRILL [RFC7455] all define OAM mechanisms based on the manageability framework of CFM [IEEE802.1ag].

Given the wide adoption of the underlying OAM concepts defined in CFM [IEEE802.1ag], it is a reasonable choice to develop the unified management framework for connection oriented OAM based on those concepts. In this document, we take the CFM [IEEE802.1ag] model and extend it to a technology independent framework and define the corresponding YANG model accordingly. The YANG model presented in this document is the base model for connection oriented OAM protocols and supports generic continuity check, connectivity verification and path discovery (traceroute). The generic YANG model for connection oriented OAM is designed to be extensible to other connection oriented technologies. Technology dependent nodes and remote process call (RPC) commands are defined in technology specific YANG models, which use and extend the base model defined here. As an example, VXLAN uses source UDP port number for flow entropy, while TRILL uses either MAC addresses, the VLAN tag or fine grain label, and/or IP addresses for flow entropy in the hashing for multipath selection. To capture this variation, corresponding YANG models would define the applicable structures as augmentation to the generic base model presented here. This accomplishes three goals: First it keeps each YANG model smaller and more manageable. Second, it allows independent development of corresponding YANG models. Third, implementations can limit support to only the applicable set of YANG models. (e.g. TRILL RBridge may only need to implement Generic model and the TRILL YANG model).
All implementations that follow the YANG framework presented in this document MUST implement the generic connection oriented YANG model presented here.

The YANG data model presented in this document is generated at the management layer. Encapsulations and state machines may differ according to each OAM protocol. A user who wishes to issue a Continuity Check command or a Loopback or initiate a performance monitoring session can do so in the same manner regardless of the underlying protocol or technology or specific vendor implementation.

As an example, consider a scenario where Loopback from device A to Device B fails. Between device A and B there are IEEE 802.1 bridges a, b and c. Let’s assume a,b and c are using CFM [IEEE802.1ag]. Upon detecting the Loopback failures, a user may decide to drill down to the lower level at different segments of the path and issue the corresponding fault verification (LBM) and fault isolation (LTM) tools, using the same API. This ability to drill down to a lower layer of the protocol stack at a specific segment within a path for fault localization and troubleshooting is referred to as "nested OAM workflow". It is a useful concept that leads to efficient network troubleshooting and maintenance workflows. The connection oriented OAM YANG model presented in this document facilitates that without needing changes to the underlying protocols.

2. Conventions used in this document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119]. In this document, these words will appear with that interpretation only when in ALL CAPS. Lower case uses of these words are not to be interpreted as carrying [RFC2119] significance.

The following notations are used within the data tree and carry the meaning as below.

Each node is printed as:
<status> <flags> <name> <opts> <type>

<status> is one of:
  + for current

<flags> is one of:
  rw for configuration data
  ro for non-configuration data
  -x for rpcs
  -n for notifications
  -w for writable

<name> is the name of the node

If the node is augmented into the tree from another module, its name is printed as <prefix>:<name>.

<opts> is one of:
  ? for an optional leaf or choice
  ! for a presence container
  * for a leaf-list or list
  [<keys>] for a list’s keys
  (choice)/:(case) Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (":")

<type> is the name of the type for leafs and leaf-lists

2.1. Terminology

CCM   - Continuity Check Message [IEEE802.1ag].
ECMP  - Equal Cost Multipath.
LBM   - Loopback Message [IEEE802.1ag].
MP    - Maintenance Point [IEEE802.1ag].
MEP   - Maintenance End Point [RFC7174] (Maintenance association End Point [IEEE802.1ag], MEG End Points [RFC6371]).
MIP   - Maintenance Intermediate Point [RFC7174] (Maintenance domain Intermediate Point [IEEE802.1ag], MEG Intermediate Point [RFC6371]).
MA    - Maintenance Association [IEEE802.1ag] [RFC7174].
MD - Maintenance Domain [IEEE802.1ag]
MEG - Maintenance Entity Group [RFC6371]
MTV - Multi-destination Tree Verification Message.
OAM - Operations, Administration, and Maintenance [RFC6291].
TRILL - Transparent Interconnection of Lots of Links [RFC6325].
CFM - Connectivity Fault Management [RFC7174] [IEEE802.1ag].
RPC - Remote Process Call.
CC - Continuity Check [RFC7276]. Continuity Checks are used to verify that a destination is reachable and therefore also referred to as reachability verification.
CV - Connectivity Verification [RFC7276]. Connectivity Verification are used to verify that a destination is connected. It are also referred to as path verification and used to verify not only that the two MPs are connected, but also that they are connected through the expected path, allowing detection of unexpected topology changes.

Proactive OAM - The proactive OAM refers to OAM actions which are carried out continuously to permit proactive reporting of fault. Proactive OAM method requires persistent configuration.

On-demand OAM - The on-demand OAM refers to OAM actions which are initiated via manual intervention for a limited time to carry out diagnostics. On-demand OAM method requires only transient configuration.

3. Architecture of Generic YANG Model for OAM

In this document we define a generic YANG model for connection oriented OAM protocols. The YANG model defined here is generic in a sense that other technologies can extend it for technology specific needs. The Generic YANG model acts as the root for other OAM YANG models. This allows users to traverse between different OAM protocols with ease through a uniform API set. This also enables a nested OAM workflow. Figure 1 depicts the relationship of different OAM YANG models to the Generic YANG Model for connection oriented OAM. The Generic YANG model for OAM provides a framework where technology-specific YANG models can inherit constructs from the base YANG models without needing to redefine them within the sub-technology.
Figure 1 depicts relationship of different YANG modules.

```
+----------+
| Connection|
| Oriented  |
| gen       |
+-----------+
```

Relationship of OAM YANG model to generic (base) YANG model

4. Overview of the OAM Model

In this document we adopt the concepts of the CFM [IEEE802.1ag] model and structure it such that it can be adapted to different connection oriented OAM protocols.

At the top of the Model is the Maintenance Domain. Each Maintenance Domain is associated with a Maintenance Name and a Domain Level.

Under each Maintenance Domain there is one or more Maintenance Association (MA). In TRILL this can be per Fine-Grained Label or for VPLS this can be per VFLS instance [RFC6136].

Under each MA, there can be two or more MEPs (Maintenance End Points). MEPs are addressed by their respective technology specific address identifiers. The YANG model presented here provides flexibility to accommodate different addressing schemes.
In the vertical direction orthogonal to the Maintenance Domain, presented are the commands. Those, in YANG terms, are the RPC commands. These RPC commands provide uniform APIs for continuity check, connectivity verification, path discovery (traceroute) and their equivalents as well as other OAM commands.

The OAM entities in the generic YANG model defined here will be either explicitly or implicitly configured using any of the OAM tools. The OAM tools used here are limited to OAM toolset specified in section 5.1 of [RFC7276]. In order to facilitate zero-touch experience, this document defines a default mode of OAM. The default mode of OAM is referred to as the Base Mode and specifies default values for each of model parameters, such as Maintenance Domain Level, Name of the Maintenance Association, Addresses of MEPs and so on. The default values of these depend on the technology. Base Mode for TRILL is defined in [RFC7455]. Base mode for other technologies and future extensions developed in IETF will be defined in their corresponding documents.

It is important to note that, no specific enhancements are needed in the YANG model to support Base Mode. Implementations that comply with this document, by default implement the data nodes of the applicable technology. Data nodes of the Base Mode are read-only nodes.

4.1. Maintenance Domain (MD) configuration

The container "domains" is the top level container within the gen-oam module. Within the container "domains", separate list is maintained per MD. The MD list uses the key MD-name-string for indexing. MD-name-string is a leaf and derived from type string. Additional name formats as defined in [IEEE802.1ag] or other standards can be included by association of the MD-name-format with an identity-ref. MD-name-format indicates the format of the augmented MD-names. MD-name is presented as choice/case construct. Thus, it is easily augmentable by derivative work.
4.2. Maintenance Association (MA) configuration

Within a given Maintenance Domain there can be one or more Maintenance Associations (MA). MAs are represented as a list and indexed by the MA-name-string. Similar to MD-name defined previously, additional name formats can be added by augmenting the name-format identity-ref and adding applicable case statements to MA-name.

          +--rw MD-name-null? empty
      +--rw md-level? MD-level

Snippet of data hierarchy related to OAM domains

4.3. Maintenance Endpoint (MEP) configuration

Within a given Maintenance Association (MA), there can be one or more Maintenance End Points (MEP). MEPs are represented as a list within the data hierarchy and indexed by the key MEP-name.

            .

Snippet of data hierarchy related to Maintenance Endpoint (MEP)

4.4. RPC definitions

The RPC model facilitates issuing commands to a NETCONF server (in
this case to the device that need to execute the OAM command) and
obtain a response. RPC model defined here abstracts OAM specific
commands in a technology independent manner.

There are several RPC commands defined for the purpose of OAM. In
this section we present a snippet of the continuity check command for
illustration purposes. Please refer to Section 4.5 for the complete
data hierarchy and Section 5 for the YANG model.

4.5. Notifications

Notification is sent on defect condition and defect clears with Maintenance Domain Name, MA Name, defect-type (The currently active defects), generating-mepid, and defect-message to indicate more details.

4.6. Monitor statistics

Grouping for monitoring statistics is to be used by Yang modules which Augment Yang to provide statistics due to pro-active OAM like CCM Messages. For example CCM Transmit, CCM Receive, CCM Errors, etc.

4.7. OAM data hierarchy

The complete data hierarchy related to the connection oriented OAM YANG model is presented below.

description
    "This YANG module defines the generic configuration,
    statistics and rpc for connection oriented OAM
    to be used within IETF in a protocol independent manner.
    Functional level abstraction is independent
    with YANG modeling. It is assumed that each protocol
    maps corresponding abstractions to its native format.
    Each protocol may extend the YANG model defined
    here to include protocol specific extensions";

  }
6. Base Mode

The Base Mode (‘default mode’ described in section 4) defines default configuration that MUST be present in the devices that comply with this document. Base Mode allows users to have "zero-touch" experience. Several parameters require technology specific definition.

6.1. MEP Address

In the Base Mode of operation, the MEP Address is by default the IP address of the interface on which the MEP is located.
6.2. MEP ID for Base Mode

In the Base Mode of operation, each device creates a single MEP associated with a virtual OAM port with no physical layer (NULL PHY). The MEP-ID associated with this MEP is zero (0). The choice of MEP-ID zero is explained below.

MEP-ID is 2 octet field by default. It is never used on the wire except when using CCM. It is important to have method that can derive MEP-ID of base mode in an automatic manner with no user intervention. IP address cannot be directly used for this purpose as the MEP-ID is much smaller field. For Base Mode of operation we propose to use MEP-ID zero (0) as the default MEP-ID.

CCM packet use MEP-ID on the payload. CCM MUST NOT be used in the Base Mode. Hence CCM MUST be disabled on the Maintenance Association of the Base Mode.

If CCM is required, users MUST configure a separate Maintenance association and assign unique value for the corresponding MEP IDs.

CFM [IEEE802.1ag] defines MEP ID as an unsigned integer in the range 1 to 8191. In this document we propose extend the range to 0 to 65535. Value 0 is reserved for MEP-ID of Base Mode operation and MUST NOT be used for other purposes.

6.3. Maintenance Association

The ID of the Maintenance Association (MA-ID) [IEEE802.1ag] has a flexible format and includes two parts: Maintenance Domain Name and Short MA name. In the Based Mode of operation, the value of the Maintenance Domain Name must be the character string "GenericBaseMode" (excluding the quotes "). In Base Mode operation Short MA Name format is set to 2-octet integer format (value 3 in Short MA Format field [IEEE802.1ag]) and Short MA name set to 65532 (0xFFFC).

7. Connection-oriented OAM YANG model applicability

"ietf-conn-oam" model defined in this document provides technology-independent abstraction of key OAM constructs for connection oriented protocols. This model can be further extended to include technology specific details, e.g., adding new data nodes with technology specific functions and parameters into proper anchor points of the base model, so as to develop a technology-specific connection-oriented OAM model.
This section demonstrates the usability of the connection-oriented YANG OAM data model to various connection-oriented OAM technologies, e.g., TRILL and MPLS-TP. Note that, in this section, we only present several snippets of technology-specific model extensions for illustrative purposes. The complete model extensions should be worked on in respective protocol working groups.

7.1. Generic YANG Model extension for TRILL OAM

The TRILL YANG module is augmenting connection oriented OAM module for both configuration and RPC commands.

The TRILL YANG module requires the base TRILL module ([I-D.ietf-trill-yang]) to be supported as there is a strong relationship between those modules.

The configuration extensions for connection oriented OAM include MD configuration extension, Technology type extension, MA configuration extension, Connectivity-Context Extension, MEP Configuration Extension, ECMP extension. In the RPC extension, the continuity-check and path-discovery RPC are extended with TRILL specific.

7.1.1. MD Configuration Extension

MD level configuration parameters are management information which can be inherited in the TRILL OAM model and set by connection oriented base model as default values. For example domain name can be set to area-ID in the TRILL OAM case. In addition, at the Maintenance Domain level, domain data node at root level can be augmented with technology type.

Note that MD level configuration parameters provides context information for management system to correlate faults, defects, network failures with location information, which helps quickly identify root causes of network failures.

7.1.1.1. Technology Type Extension

No TRILL technology type has been defined in the connection oriented base model. Therefore a technology type extension is required in the TRILL OAM model. The technology type "trill" is defined as an identity that augments the base "technology-types" defined in the connection oriented base model:
identity trill{
    base goam:technology-types;
    description
      "trill type";
}

7.1.2. MA Configuration Extension

MA level configuration parameters are management information which can be inherited in the TRILL OAM model and set by connection oriented base model as default values. In addition, at the Maintenance Association (MA) level, MA data node at the second level can be augmented with connectivity-context extension.

Note that MA level configuration parameters provides context information for management system to correlate faults, defects, network failures with location information, which helps quickly identify root causes of network failures.

7.1.2.1. Connectivity-Context Extension

In TRILL OAM, one example of connectivity-context is either a 12 bit VLAN ID or a 24 bit Fine Grain Label. The connection oriented base model defines a placeholder for context-id. This allows other technologies to easily augment that to include technology specific extensions. The snippet below depicts an example of augmenting connectivity-context to include either VLAN ID or Fine Grain Label.

    augment /goam:domains/goam:domain/goam:MAs
      /goam:MA /goam:connectivity-context:
        +--:(connectivity-context-vlan)
          |  +--rw connectivity-context-vlan?   vlan
        +--:(connectivity-context-fgl)
          +--rw connectivity-context-fgl?    fgl

7.1.3. MEP Configuration Extension

The MEP configuration definition in the connection oriented base model already supports configuring the interface of MEP with either MAC address or IP address. In addition, the MEP address can be represented using a 2 octet RBridge Nickname in TRILL OAM . Hence, the TRILL OAM model augments the MEP configuration in base model to add a nickname case into the MEP address choice node as follows:

    augment /goam:domains/goam:domain/goam:MAs
      /goam:MA/ goam:MEP/goam:mep-address:
        +--:( mep-address-trill)
          |  +--rw mep-address-trill?  tril-rb-nickname
In addition, at the Maintenance Association Endpoint (MEP) level, MEP data node at the third level can be augmented with ECMP extension.

7.1.3.1. ECMP Extension

Since TRILL supports ECMP path selection, flow-entropy in TRILL is defined as a 96 octet field in the LIME model extension for TRILL OAM. The snippet below illustrates its extension.

```
augment /goam:domains/goam:domain/goam:MAs/goam:MA/goam:MEP:
    +--rw flow-entropy-trill?  flow-entropy-trill
    +--rw flow-entropy-trill?  flow-entropy-trill
```

7.1.4. RPC extension

In the TRILL OAM YANG model, the continuity-check and path-discovery RPC commands are extended with TRILL specific requirements. The snippet below depicts an example of illustrates the TRILL OAM RPC extension.
augment /goam:continuity-check/goam:input:
  +--ro (out-of-band)?
    |  +--:(ipv4-address)
    |    |  +--ro ipv4-address? inet:ipv4-address
    |  +--:(ipv6-address)
    |    |  +--ro ipv6-address? inet:ipv6-address
    +--:(trill-nickname)
      +--ro trill-nickname? tril-rb-nickname
      +--ro diagnostic-vlan? boolean
augment /goam:continuity-check/goam:input:
  +--ro flow-entropy-trill? flow-entropy-trill
augment /goam:continuity-check/goam:output:
  +--ro upstream-rbridge? tril-rb-nickname
  +--ro next-hop-rbridge* tril-rb-nickname
augment /goam:path-discovery/goam:input:
  +--ro (out-of-band)?
    |  +--:(ipv4-address)
    |    |  +--ro ipv4-address? inet:ipv4-address
    |  +--:(ipv6-address)
    |    |  +--ro ipv6-address? inet:ipv6-address
    +--:(trill-nickname)
      +--ro trill-nickname? tril-rb-nickname
      +--ro diagnostic-vlan? boolean
augment /goam:path-discovery/goam:input:
  +--ro flow-entropy-trill? flow-entropy-trill
augment /goam:path-discovery/goam:output/goam:response:
  +--ro upstream-rbridge? tril-rb-nickname
  +--ro next-hop-rbridge* tril-rb-nickname

7.2. Generic YANG Model extension for MPLS-TP OAM

The MPLS-TP OAM YANG module can augment connection oriented OAM Module with some technology-specific details. And the [mpls-tp-oam-yang] presents the YANG Data model for MPLS-TP OAM.

The configuration extensions for connection oriented OAM include MD configuration extension, Technology type extension, Sub Technology Type Extension, MA configuration extension, MEP Configuration Extension.

7.2.1. MD Configuration Extension

MD level configuration parameters are management information which can be inherited in the MPLS-TP OAM model and set by LIME base model as default values. For example domain name can be set to area-ID or the provider’s Autonomous System Number (ASN) [RFC6370] in the MPLS-TP OAM case. In addition, at the Maintenance Domain level, domain data
node at root level can be augmented with technology type and sub-technology type.

Note that MD level configuration parameters provides context information for management system to correlate faults, defects, network failures with location information, which helps quickly identify root causes of network failures

7.2.1.1. Technology Type Extension

No MPLS-TP technology type has been defined in the connection oriented base model, hence it is required in the MPLS OAM model. The technology type "mpls-tp" is defined as an identity that augments the base "technology-types" defined in the connection oriented base model:

```yaml
identity mpls-tp{
    base goam:technology-types;
    description
        "mpls-tp type";
}
```

7.2.1.2. Sub Technology Type Extension

In MPLS-TP, since different encapsulation types such as IP/UDP Encapsulation, PW-ACH encapsulation can be employed, the "technology-sub-type" data node is defined and added into the MPLS OAM model to further identify the encapsulation types within the MPLS-TP OAM model. Based on it, we also define a technology sub-type for IP/UDP encapsulation and PW-ACH encapsulation. Other Encapsulation types can be defined in the same way. The snippet below depicts an example of several encapsulation types.
identity technology-sub-type {
  description
  "certain implementations can have different
  encapsulation types such as ip/udp, pw-ach and so on.
  Instead of defining separate models for each
  encapsulation, we define a technology sub-type to
  further identify different encapsulations.
  Technology sub-type is associated at the MA level";
}

  identity technology-sub-type-udp {
    base technology-sub-type;
    description
    "technology sub-type is IP/UDP encapsulation";
  }

  identity technology-sub-type-ach {
    base technology-sub-type;
    description
    "technology sub-type is PW-ACH encapsulation";
  }

augment "/goam:domains/goam:domain/goam:MAs/goam:MA" {
  leaf technology-sub-type {
    type identityref {
      base technology-sub-type;
    }
  }
}

7.2.2. MA Configuration Extension

MA level configuration parameters are management information which
can be inherited in the MPLS-TP OAM model and set by Connection
Oriented base model as default values. One example of MA Name could
be MEG LSP ID or MEG Section ID or MEG PW ID[RFC6370].

Note that MA level configuration parameters provides context
information for management system to correlate faults, defects,
network failures with location information, which helps quickly
identify root causes of network failures.

7.2.3. MEP Configuration Extension

In MPLS-TP, MEP-ID is either a variable length label value in case of
G-ACH encapsulation or a 2 octet unsigned integer value in case of
IP/UDP encapsulation. One example of MEP-ID is MPLS-TP LSP_MEP_ID
[RFC6370]. In the connection-oriented base model, MEP-ID is defined
as a choice/case node which can support an int32 value, and the same definition can be used for MPLS-TP with no further modification. In addition, at the Maintenance Association Endpoint (MEP) level, MEP data node at the third level can be augmented with Session extension and interface extension.

8. Security Considerations

The YANG module defined in this memo is designed to be accessed via the NETCONF protocol [RFC6241] [RFC6241]. The lowest NETCONF layer is the secure transport layer and the mandatory-to-implement secure transport is SSH [RFC6242] [RFC6242]. The NETCONF access control model [RFC6536] [RFC6536] provides the means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

There are a number of data nodes defined in the YANG module which are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., <edit-config>) to these data nodes without proper protection can have a negative effect on network operations.

The vulnerable "config true" subtrees and data nodes are the following:

/goam:domains/goam:domain/
/goam:domains/goam:domain/goam:MAs/goam:MA/

Unauthorized access to any of these lists can adversely affect OAM management system handling of end-to-end OAM and coordination of OAM within underlying network layers. This may lead to inconsistent configuration, reporting, and presentation for the OAM mechanisms used to manage the network.

9. IANA Considerations

This document registers a URI in the IETF XML registry [RFC3688] [RFC3688]. Following the format in RFC 3688, the following registration is requested to be made:

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

This document registers a YANG module in the YANG Module Names registry [RFC6020].

prefix: goam reference: RFC XXXX

10. Acknowledgments

Giles Heron came up with the idea of developing a YANG model as a way of creating a unified OAM API set (interface), work in this document is largely an inspiration of that. Alexander Clemm provided many valuable tips, comments and remarks that helped to refine the YANG model presented in this document.

Carlos Pignataro, David Ball, Mahesh Jethanandani, Benoit Claise, Ladislav Lhotka, GUBALLA JENS, Yuji Tochio, Gregory Mirsky, Huub van Helvoort, Tom Taylor, Dapeng Liu, Mishael Wexler, Adi Molkho participated and contributed to this document.

Abstract

This document presents a base YANG Data model for connectionless OAM protocols. It provides a technology-independent abstraction of key OAM constructs for connectionless protocols. Based model presented here can be extended to include technology specific details. This is leading to uniformity between OAM protocols and support nested OAM workflows (i.e., performing OAM functions at different or same levels through a unified interface).
1. Introduction

Operations, Administration, and Maintenance (OAM) are important networking functions that allow operators to:

1. Monitor networks connections (Reachability Verification, Continuity Check).
2. Troubleshoot failures (Fault verification and localization).
3. Monitor Performance

An overview of OAM tools is presented at [RFC7276].
Ping and Traceroute [RFC792], [RFC4443] are well-known fault verification and isolation tools, respectively, for IP networks. Over the years, different technologies have developed similar tools for similar purposes.

In this document, we present a base YANG Data model for connectionless OAM protocols which supports generic continuity or reachability check, and path discovery. The generic YANG model for connectionless OAM is designed such that it can be extended to cover various connectionless technologies. Technology dependent nodes and RPC (remote process call) commands are defined in technology specific YANG models, which use and extend the base model defined here.

2. Conventions used in this document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

The following terms are defined in [RFC6241] and are not redefined here:

- o client
- o configuration data
- o server
- o state data

The following terms are defined in [RFC6020] and are not redefined here:

- o augment
- o data model
- o data node

The terminology for describing YANG data models is found in [RFC6020].

2.1. Terminology

TP - Test Point

MAC - Media Access Control
BFD - Bidirectional Forwarding Detection

TLV - Type Length Value

RPC - A Remote Procedure Call, as used within the NETCONF protocol

2.2. Tree Diagrams

A simplified graphical representation of the data model is used in this document. The meaning of the symbols in these diagrams is as follows:

Each node is printed as:

<status> <flags> <name> <opts> <type>

<status> is one of:
+  for current
x  for deprecated
o  for obsolete

<flags> is one of:

  rw for configuration data
  ro for non-configuration data
  ~x for rpcs
  ~n for notifications

<name> is the name of the node

If the node is augmented into the tree from another module, its name is printed as <prefix>:<name>.

<opts> is one of:

  ?  for an optional leaf or choice
  !  for a presence container
  *  for a leaf-list or list
  [<keys>] for a list’s keys

<type> is the name of the type for leafs and leaf-lists
3. Overview of the Connectionless OAM Model

At the top of the Model there is an oper container for ipv4 and ipv6 session statistics. Grouping is also defined for common per session continuity-check statistics. This statistics is applicable for long-lived OAM sessions. Multiple test-point-location-list keyed using test point location type is augmented to network topology. Under test-point-location-list, there is one or more test-point-locations. Each test-point-location is associated with vrf, oam-layers, tools, and technology. The vrf is used to describe the corresponding network instance. The technology indicate oam technology details. The tools is used to describe oam tools supported. The oam-layers is used to indicate relation of test point with other test points. The level in oam-layers indicate whether related oam test point is client layer, server layer or same or stitched layer. The Model is augmented to /nd:networks/nd:network/nd:node. rpc for continuity-check and path discovery.

Under test-point-locations, there are tp-addresses, technology type, tools, and oam layer which describe the attributes associated with test-point.

3.1. TP address

In connectionless OAM, the tp address is defined with the following type:

- MAC address
- IPv4 or IPv6 address
- a pair of source, destination addresses, and interface (Useful for BFD)
- FEC
- TLV address (RFC6428 (Figure 4, 5, and 6))

3.2. Tools

In connectionless OAM, the tools attribute is used to describe a toolset for fault detection and isolation, and for performance measurement. And it can serve as a constraint condition when the base model be extended to specific OAM technology. For example, to fulfill the icmp ping configuration, the "../coam:tools-ip/coam/rfc792" should be set to "true", and then the lime base model should be augmented with icmp ping specific details.
3.3. Passive OAM

Passive OAM [1] defines mechanisms to record OAM information in the data packet itself while the packet traverses a particular network domain. Passive OAM defines a set of meta-data that is carried as part of the live traffic. The draft identifies several transport options for carrying passive OAM meta-data in packets and include IPv4, IPv6 as well as VXLAN-GPE, SR for IPv6 and NSH. Passive OAM is meant to complement active OAM mechanisms such as ping or trace route. Passive OAM mechanisms can be leveraged where current active OAM methods do not apply or do not offer the desired results, such as proving that a certain set of traffic takes a pre-defined path, SLA verification for the live data traffic, detailed statistics on traffic distribution paths in ECMP networks or scenarios where active OAM traffic is potentially handled differently from regular data traffic by the network devices. Passive OAM encompasses path trace, path packet counters and proof of transit sub-features and are further described below.

3.3.1. Path Trace

Path-trace feature is part of the passive OAM feature set, where meta-data is expected to be collected at every hop that a packet traverses, i.e. in a typical deployment all nodes in an passive OAM domain would participate in the domain and thus be transit nodes, encapsulating or decapsulating nodes. The network diameter of the domain is assumed to be known. The passive OAM path-trace decapsulating node removes the meta-data and process and/or export the meta-data. Some examples of the meta-data include node identification, incoming interface identification, outgoing interface identification, timestamp or generic application specific meta-data.

3.3.2. Path Packet Counters

Path-packet-counters feature is part of the passive OAM feature set, where the meta-data carried is to be interpreted by the passive OAM domain’s encapsulating and decapsulating nodes. Sequence numbers are the main meta-data added and can be used to detect packet loss, packet reordering or packet duplication.

3.3.3. Proof of Transit

Proof of transit feature is part of the passive OAM feature set, where the path or the service chain is verified. Service or path verification uses methods like nested hashing or nested encryption of the meta-data. By definition of a service chain or a path, some of the nodes in the domain participate and some do not.
3.4. OAM-layers

OAM-layers is referred to a list of OAM layers above and below that are related to current test point. This allows users to easily navigate up and down to efficiently troubleshoot a connectivity issue. In this model, we have kept level default as 0, as none connectionless network OAM uses layer or level in its mode. Level is provided for scenarios where it might be possible to define layering relationship as it can be used to tie up interworking of fault at related oam layers. For example, there is a defect in the upstream path of the testpoint, the upstream path belongs to server layer LSP and the level is set to "-1", the downstream path of the test point belongs to client layer LSP and the level is set to "1", then we can stitch server layer LSP and client layer LSP at different level and track defect along this path. In another case, if the upstream path and downstream path of the test point is in the same level, the level is set to "0". The snippet below depicts an example of OAM layers.

```
list oam-layers {
  key "index";
  leaf index {
    type uint16 {
      range "0..65535";
    }
  }
  leaf level {
    type int32 {
      range "-1..1";
      description "Level";
    }
    ordered-by user;
    description "list of related oam layers.";
  }
}
```

3.5. rpc definitions

The rpc model facilitates issuing commands to a NETCONF server (in this case to the device that need to execute the OAM command) and obtaining a response.

In this document, we summarize the common OAM functions and define the generic rpc commands: continuity-check and path-discovery. In practice, these commands are supported by corresponding technology-specific OAM tools [RFC7276]. For example, for the IP OAM model, the
continuity-check rpc corresponds to the IP Ping, while the path-
discovery rpc command corresponds to IP Traceroute.

Note that the rpc command presented in this document is the base
building block, which is used to derive a model for a technology-
specific OAM(i.e., icmp ping, lsp ping), the base building block
should be extended with corresponding technology specific parameters.

continuity-check:
rpc continuity-check {
  if-feature continuity-check;
  description
    "Generates continuity-check as per RFC7276.";

}

Snippet of data hierarchy related to rpc calls

3.6. Relation with other OAM YANG Model

In this document we define a generic YANG model for connectionless OAM protocols. The YANG model defined here is generic such that other technologies can extend it for technology specific needs. The Generic YANG model acts as the root for other OAM YANG models. This allows users to traverse between different OAM protocols at ease through a uniform API set. The Generic YANG model for OAM provides a framework where technology- specific YANG models can choose to inherit constructs from the base YANG models without needing to redefine them within the sub-technology.
3.7. Notifications

In this document we define notifications for passive oam. They are passive oam proof of transit triggered notification, and passive oam path packet counters triggered notification.

3.8. Proof of transit notification

It’s generated with node information, ACL name associated with flow, and failure code from the device, and failed count, i.e. number of packet failed to offer proof of transit.

3.9. Path packet counter notification

It’s generated with node information, ACL name associated with flow, and failure code from the device, and failed drop count, failed reorder count failed out of sequence, and failed dup count.

3.10. OAM data hierarchy

The complete data hierarchy related to the OAM YANG model is presented below.

description
    "This YANG module defines the generic configuration,
    statistics and rpc for connectionless OAM to be
    used within IETF in a protocol independent manner.
    Functional level abstraction is independent with
    YANG modeling. It is assumed that each protocol maps
    corresponding abstractions to its native format.
    Each protocol may extend the YANG model defined
    here to include protocol specific extensions";

    description
        "Initial revision. - 01 version";
    reference "";
}
/* features */
feature connection-less {
    description
        "this feature indicates that OAM solution is connection less.";
}
feature continuity-check {
    description
        "This feature indicates that the server supports
executing continuity check OAM command and returning a response. Servers that do not advertise this feature will not support executing continuity check command or rpc model for continuity check command.

feature path-discovery {
    description
    "This feature indicates that the server supports executing path discovery OAM command and returning a response. Servers that do not advertise this feature will not support executing path discovery command or rpc model for path discovery command."
}

feature path-trace {
    description
    "This feature indicates that the server supports configuration and execution of the in-band passive path tracing feature. Servers that do not advertise this feature will not support executing in-band path trace and the relevant configuration.

Path-trace feature is part of the passive-oam feature set, where meta-data is expected to be collected at every hop that a packet traverses, i.e. in a typical deployment all nodes in an passive-oam domain would participate in the domain and thus be transit nodes, encapsulating or decapsulating nodes. The network diameter of the domain is assumed to be known. The passive-oam path-trace decapsulating node removes the meta-data and process and/or export the meta-data.

Some examples of the meta-data include node identification, incoming interface identification, outgoing interface identification, timestamp or generic application specific meta-data."
}

feature path-packet-counters {
    description
    "This feature indicates that the server supports executing passive OAM via path packet counter options. Servers that do not advertise this feature will not support executing passive OAM path packet counters.

Path-packet-counters feature is part of the passive-oam feature set, where the meta-data carried is to be interpreted by the passive-oam domain’s encapsulating and decapsulating nodes.\n}
nodes. Sequence numbers are the main meta-data added and can be used to detect packet loss, packet reordering or packet duplication.

feature proof-of-transit {
  description
  "This feature indicates that the server supports executing passive proof of transit OAM options. Servers that do not advertise this feature will not support executing proof-of-transit.

  Proof-of-transit feature is part of the passive-oam feature set, where the path or the service chain is verified. Service or path verification uses methods like nested hashing or nested encryption of the meta-data. By definition of a service chain or a path, some of the nodes in the domain participate and some do not."
}

Generic YANG Data Model for Connection Less Operations, Administration, and Maintenance (OAM) protocols
draft-kumar-lime-yang-connectionless-oam-05

Abstract

This document presents a base YANG Data model for connectionless OAM protocols. It provides a technology-independent abstraction of key OAM constructs for connectionless protocols. The Base model presented here can be extended to include technology specific details. This is leading to uniformity between OAM protocols and support nested OAM workflows (i.e., performing OAM functions at different or same levels through a unified interface).

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 20, 2017.

1. Introduction

Operations, Administration, and Maintenance (OAM) are important networking functions that allow operators to:

1. Monitor networks connections (Reachability Verification, Continuity Check).
2. Troubleshoot failures (Fault verification and localization).
3. Monitor Performance

An overview of OAM tools is presented at [RFC7276].

Ping and Traceroute [RFC792], [RFC4443] are well-known fault verification and isolation tools, respectively, for IP networks. Over the years, different technologies have developed similar tools for similar purposes.

In this document, we present two modules, one to represent the base independent and stand-alone YANG data model for connectionless OAM protocols and the other one focuses on data retrieval procedures like RPCs. The split module approach avoids mixing the models for the retrieved-data from the retrieval procedures. It is expected that retrieval procedures would evolve faster than the data model and will allow new procedures to be defined for retrieval of the same data defined by the base data model. This also allows the data model to change at its own pace.

2. Conventions used in this document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

The following terms are defined in [RFC6241] and are not redefined here:

- client
- configuration data
- server
- state data

The following terms are defined in [RFC6020] and are not redefined here:

- augment
- data model
- data node

The terminology for describing YANG data models is found in [RFC6020].
2.1. Terminology

TP - Test Point

MAC - Media Access Control

BFD - Bidirectional Forwarding Detection

TLV - Type Length Value

RPC - A Remote Procedure Call, as used within the NETCONF protocol

2.2. Tree Diagrams

A simplified graphical representation of the data model is used in this document. The meaning of the symbols in these diagrams is as follows:

Each node is printed as:

<status> <flags> <name> <opts> <type>

<status> is one of:
+ for current
x for deprecated
o for obsolete

<flags> is one of:

rw for configuration data
ro for non-configuration data
-x for rpcs
-n for notifications

:name: is the name of the node

If the node is augmented into the tree from another module, its name is printed as <prefix>:<name>.
3. Overview of the Connectionless OAM Model

At the top of the Model, there is an oper container for session statistics. Grouping is also defined for common session statistics and these are applicable for proactive OAM sessions. Multiple test-point-locations keyed using technology specific keys (e.g., IPv4 address for IPv4 locations) are possible by augmented network topology nodes. Each test-point-location is chosen based on location-type which when chosen, leads to a container that includes a list of test-point-locations keyed by technology specific keys. Each test point location includes a test-point-location-info. The test-point-location-info includes tp-technology, tp-tools, and connectionless-oam-layers. The groupings of tp-address and tp-address-vrf are kept out of test-point-location-info to make it addressing agnostic and allow varied composition. Depending upon the choice of the location-type (determined by the tp-address-vrf), the containers differ in its composition of test-point-locations while the test-point-location-info, is a common aspect of every test-point-location. The vrf is used to describe the corresponding network instance. The tp-technology indicate oam technology details. The tp-tools describe the oam tools supported. The connectionless-oam-layers is used to describe the relationship of one test point with other test points. The level in oam-layers indicate whether related oam test point is client layer, server layer or same or stiched layer. The Model is augmented to /nd:networks/nd:network/nd:node using Test Point Locations defined below.

3.1. TP Address

In connectionless OAM, the tp address is defined with the following type:

- MAC address
- IPv4 or IPv6 address
- a pair of source, destination addresses, and interface (Useful for BFD)
3.2. Tools

In connectionless OAM, the tools attribute is used to describe a toolset for fault detection and isolation, and for performance measurement. And it can serve as a constraint condition when the base model be extended to specific OAM technology. For example, to fulfill the icmp ping configuration, the "/coam:tools-ip/coam:rfc792" should be set to "true", and then the lime base model should be augmented with icmp ping specific details.

3.3. OAM-layers

As typical networks have a multi-layer architecture, the set of OAM protocols similarly take a multi-layer structure; each layer has its own OAM protocols [RFC7276] and is corresponding to specific network portion or path and has associated test points. OAM-layers is referred to a list of upper layer, lower layer that are related to current test point. This allow users to easily navigate up and down to efficiently troubleshoot a connectivity issue at different layer. In this model, we have kept level default as 0, when all test points are located at the same layer. Level is provided for scenarios where it might be possible to define layering relationship as it can be used to stitching fault at related oam layers. For example, there is a network in which data traffic between two customer edges is transported over three consecutive network portions, the current test point is located in the second network portion. If there is a defect in the first network portion is located at the upstream of the second network portion, the level of the first network portion is set to "-1". If the third network portion is located at the downstream of the second network portion and the level is set to "1". In another case, if the first network portion and the third network portion is in the same level of the second network portion, the level is set to "0". The snippet below depicts an example of OAM layers.
list oam-layers {
  key "index";
  leaf index {
    type uint16 {
      range "0..65535";
    }
  }
  leaf level {
    type int32 {
      range "-1..1";
    }
    description
      "Level";
  }
  ordered-by user;
  description
    "list of related oam layers.";
}

3.4. Test Point Locations Information

This is a generic grouping for Test Point Locations Information. It provide details of Test Point Location using Tools, OAM-Layers grouping defined above.

3.5. Test Point Locations

This is a generic grouping for Test Point Locations. Choice statement is used to define locations types, for example ipv4-location-type, ipv6-location-type, etc. Container is defined under each location type containing list keyed to test point address, Test Point Location Information defined in section above, and routing instance vrf name if required.

3.6. Path discovery data

This is a generic grouping for path discovery data model that can be retrieved by any data retrieval methods including RPCs. Path discovery data output from methods, includes src-test-point, dst-test-point, sequence-number, hop-cnt, session statistics of various kinds, path verification and path trace related information. Path discovery includes data to be retrieved on a per-hop basis via a list of path-trace-info-list which includes information like timestamps, ingress-interface, egress-interface and app-meta-data. The path discovery data model is made generic enough to allow active, passive and hybrid OAMs to do the retrieval. None of the fields are made mandatory for that reason.
3.7. Continuity check data

This is a generic grouping for continuity check data model that can be retrieved by any data retrieval methods including RPCs. Continuity check data output from methods, includes src-test-point, dst-test-point, sequence-number, hop-cnt and session statistics of various kinds. The continuity check data model is made generic enough to allow active, passive and hybrid OAMs to do the retrieval. None of the fields are made mandatory for that reason.

3.8. RPC definitions

The rpc model described here as a separate model outside of the data model, facilitates issuing commands to a NETCONF server (in this case to the device that need to execute the OAM command) and obtaining a response.

Under connectionless-oam-methods module, we summarize the common OAM functions and define the generic rpc commands: continuity-check and path-discovery. In practice, these commands are supported by corresponding technology-specific OAM tools [RFC7276]. For example, for the IP OAM model, the continuity-check rpc corresponds to the IP Ping, while the path-discovery rpc command corresponds to IP Traceroute.

Note that the rpc command presented in this document is the base building block, which is used to derive a model for a technology-specific OAM(i.e., icmp ping, lsp ping), the base building block should be extended with corresponding technology specific parameters. To facilitate this and for future enhancements to data retrieval methods, the RPCs are captured under a separate module.

The generic path-discovery-data and continuity-check-data are used as data outputs from the different RPCs described in the document. Similar methods including other RPCs can retrieve the data using the same data model.

```yml
rpc continuity-check {
  if-feature coam:continuity-check;
  description
    "Generates continuity-check as per RFC7276.";
  input {
    container destination-tp {
      uses coam:tp-address;
      description
        "destination test point.";
    }
  }
  uses coam:session-type;
}
leaf source-interface {
    type if:interface-ref;
    description "source interface.";
}

leaf outbound-interface {
    type if:interface-ref;
    description "outbound interface.";

      description
      "vrf";
    }
    leaf max-ttl {
      type uint8;
      default "255";
      description
      "max ttl.";
    }
  }
  output {

list response-list {
    key "response-index";
    description "path discovery response list."
    leaf response-index {
        type uint32;
        description "response index.";
    }
    leaf status-code {
        type int32;
        description "error code is ";
    }
    leaf status-sub-code {
        type uint8;
        description "sub code is ";
    }
}

uses coam:path-discovery-data;
}

Snippet of data hierarchy related to rpc calls

3.9. Relation with other OAM YANG Model

In this document we define a generic YANG data model for connectionless OAM protocols. The other model defined adds generic data-retrieval methods. The YANG data model defined here is generic such that other technologies can extend it for technology specific needs. The Generic YANG model acts as the root for other OAM YANG models. This allows users to traverse between different OAM protocols at ease through a uniform API set. The Generic YANG model for OAM provides a framework where technology- specific YANG models can choose to inherit constructs from the base YANG models without needing to redefine them within the sub-technology.

3.10. OAM data hierarchy

The complete data hierarchy related to the OAM YANG model is presented below.

module: ietf-connectionless-oam
    +-ro oper {continuity-check}?
---ro cc-ipv4-sessions-statistics
  +--ro cc-session-statistics
    +--ro session-count?              uint32
    +--ro session-up-count?           uint32
    +--ro session-down-count?         uint32
    +--ro session-admin-down-count?   uint32
  +--ro cc-ipv6-sessions-statistics
    +--ro cc-session-statistics
      +--ro session-count?              uint32
      +--ro session-up-count?           uint32
      +--ro session-down-count?         uint32
      +--ro session-admin-down-count?   uint32

augment /nd:networks/nd:network/nd:node:
  --rw tp-address-type-value?                           identityref
    --rw (location-type)?

Kumar, et al. Expires January 20, 2017
"This YANG module defines the generic configuration, data model, statistics for connectionless OAM to be used within IETF in a protocol independent manner. Functional level abstraction is independent with YANG modeling. It is assumed that each protocol maps corresponding abstracts to its native format. Each protocol may extend the YANG model defined here to include protocol specific extensions";

This YANG module defines the RPCs for connectionless OAM to be used within IETF in a protocol Independent manner. Functional level abstraction is indendent with YANG modeling. It is assumed that each protocol maps corresponding abstracts to its native format. Each protocol may extend the YANG model defined here to include protocol specific extensions.
