Problem Statement for Simplified Use of Policy Abstractions (SUPA)
draft-bi-supa-problem-statement-01

Abstract

Simplified Use of Policy Abstractions (SUPA) defines a set of rules that define how services are designed, delivered, and operated within an operator’s environment independent of any one particular service or networking device. SUPA expresses policy rules using a generic policy information model, which serves as a unifying influence to enable different data model implementations to be simultaneously developed.

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 8, 2017.
1. Introduction

The rapid growth in the variety and importance of traffic flowing over increasingly complex enterprise and service provider network architectures makes the task of network operations and management applications and deploying new services much more difficult. In addition, network operators want to deploy new services quickly and efficiently. Two possible mechanisms for dealing with this growing difficulty are the use of software abstractions to simplify the design and configuration of monitoring and control operations and the use of programmatic control over the configuration and operation of such networks. Policy-based management can be used to combine these two mechanisms into an extensible framework.

Policy rules can be used to express high-level network operator requirements directly, or from a set of management applications, to a network management or element system. The network management or element system can then control the configuration and/or monitoring of network elements and services.

Simplified Use of Policy Abstractions (SUPA) will define a generic policy information model (GPIM) [SUPA-info-model] for use in network operations and management applications. The GPIM defines concepts and terminology needed by policy management independent of the form and content of the policy rule. The ECA Policy Rule Information Model (EPRIM) [SUPA-info-model] extends the GPIM to define how to build policy rules according to the event-condition-action paradigm.

Both the GPIM and the EPRIM are targeted at controlling the configuration and monitoring of network elements throughout the service development and deployment lifecycle. The GPIM and the EPRIM will both be translated into corresponding YANG [RFC6020] modules that define policy concepts, terminology, and rules in a generic and interoperable manner; additional YANG modules may also be defined from the GPIM and/or EPRIM to manage specific functions.

The key benefit of policy management is that it enables different network elements and services to be instructed to behave the same way, even if they are programmed differently. Management applications will benefit from using policy rules that enable scalable and consistent programmatic control over the configuration and monitoring of network elements and services.

1.1. Problem Statement

Network operators must construct networks of increasing size and complexity in order to improve their availability and quality, as more and more business services depend on them.

Currently, different technologies and network elements require different forms of the same policy that governs the production of
network configuration snippets. The power of policy management is its applicability to many different types of systems, services, and networking devices. This provides significant improvements in configuration agility, error detection, and uptime for operators.

Many different types of actors can be identified that can use a policy management system, including applications, end-users, developers, network administrators, and operators. Each of these actors typically has different skills and uses different concepts and terminologies. For example, an operator may want to express that only Platinum and Gold users can use streaming and interactive multimedia applications. As a second example, an operator may want to define a more concrete policy rule that looks at the number of dropped packets. If, for example, this number exceeds a certain threshold value, then the applied queuing, dropping and scheduling algorithms could be changed in order to reduce the number of dropped packets. The power of SUPA is that both of these examples may be abstracted. For example, in the latter example, different thresholds and algorithms could be defined for different classes of service.

1.2. Proposed Solution

SUPA enables network operators to express policies to control network configuration and monitoring data models in a generic manner. The configuration and monitoring processes are independent of device, as well as domain or type of application, and result in configuration according to YANG data models.

Both of the examples in section 1.1 can be referred to as "policy rules", but they take very different forms, since they are defined at different levels of abstraction and likely authored by different actors. The first example described a very abstract policy rule, and did not contain any technology-specific terms, while the second example included more concrete policy rules and likely used technical terms of a general (e.g., IP address range and port numbers) as well as vendor-specific nature (e.g., specific algorithms implemented in a particular device). Furthermore, these two policy rules could affect each other. For example, Gold and Platinum users might need different device configurations to give the proper QoS markings to their streaming multimedia traffic. This is very difficult to do if a common policy framework does not exist.

Note that SUPA is not limited to any one type of technology. While the above two policies could be considered "QoS" policies, other examples include:

- network elements must not accept passwords for logins

- all SNMP agents in this network must drop all SNMP traffic unless it is originating from, or targeting, the management network
- Periodically perform workload consolidation if average CPU utilization falls below X%

The above three examples are not QoS related; this emphasizes the utility of the SUPA approach in being able to provide policies to control different types of network element configuration and/or monitoring snippets.

There are many types of policies. SUPA differentiates between "management policies" and "embedded policies". Management policies are used to control the configuration of network elements. Management policies can be interpreted externally to network elements, and the interpretation typically results in configuration changes of collections of network elements. In contrast, "embedded policies" are policies that are embedded in the configuration of network elements, and are usually interpreted on network elements in isolation. Since embedded policies are interpreted in the network device, they are typically composed in a very specific fashion to run at near-realtime timescales.

1.3. Value of the SUPA Approach

SUPA will achieve an optimization and reduction in the amount of work required to define and implement policy-based data models in the IETF. This is due to the generic and extensible framework provided by SUPA.

SUPA defines policy independent of where it is located. Other WGs are working on embedding policy in the configuration of a network element; SUPA is working on defining policies that can be interpreted external to network elements (i.e., management policies). Hence, SUPA policies can be used to define the behavior of and interaction between embedded policies.

Since the GPIM defines common policy terminology and concepts, it can be used to both define more specific policies as part of a data model as well as derive a (more abstract) information model from a (more specific) data model.

This latter approach may be of use in discovering common structures that occur in data models that have been designed in isolation of each other.

The SUPA policy framework defines a set of consistent, flexible, and scalable mechanisms for monitoring and controlling resources and services. It may be used to create a management and operations interface that can enable existing IETF data models, such as those from I2RS and L3SM, to be managed in a unified way that is independent of application domain, technology and vendor. Resource and service management become more effective, because policy
defines the context that different operations, such as configuration and monitoring, are applied to.

2. Application of Generic Policy-based Management

This section provides examples of how SUPA can be used to define different types of policies. Examples applied to various domains, including system management, operations management, access control, routing, and service function chaining, are also included. Note that typical use cases and the applicability of SUPA policy models are provided in [SUPA-Applicability].

ECA policies are rules that consist of an event clause, a condition clause, and an action clause.

Network Service Management Example

Event: too many interface alarms received from an L3VPN service
Condition: alarms resolve to the same interface within a specified time period
Action: if error rate exceeds x% then put L3VPN service to Error State and migrate users to one or more new L3VPNs

Security Management Example

Event: anomalous traffic detected in network
Condition: determine the severity of the traffic
Action: apply one or more actions to affected NEs based on the type of the traffic detected (along with other factors, such as the type of resource being attacked if the traffic is determined to be an attack)

Traffic Management Examples

Event: edge link close to being overloaded by incoming traffic
Condition: if link utilization exceeds Y% or if link utilization average is increasing over a specified time period
Action: change routing configuration to other peers that have better metrics

Event: edge link close to be overloaded by outgoing traffic
Condition: if link utilization exceeds Z% or if link utilization average is increasing over a specified time period
Action: reconfigure affected nodes to use source-based routing to balance traffic across multiple links
Service Management Examples

Event: alarm received or periodic time period check
Condition: CPU utilization level comparison
Action: no violation: no action
violation:
1) determine workload profile in time interval
2) determine complementary workloads (e.g., whose peaks are at different times in day)
3) combine workloads (e.g., using integer programming)

Event: alarm received or periodic time check
Condition: if DSCP == AFxy and
throughput < T% or packet loss > P%
Action: no: no action
yes: remark to AFx’y’; reconfigure queuing;
configure shaping to S pps; ...

Note: it is possible to construct an ECA policy rule that is directly tied to configuration parameters.

3. Conclusions: the Value of SUPA

SUPA can be used to define high-level, possibly network-wide policies to create interoperable network element configuration snippets. SUPA expresses policies and associated concepts using a generic policy information model, and produces generic policy YANG data modules. SUPA focuses on management policies that control the configuration of network elements. Management policies can be interpreted outside of network elements, and the interpretation typically results in configuration changes to collections of network elements.

Policies embedded in the configuration of network elements are not in the scope of SUPA. In contrast to policies targeted by SUPA, embedded policies are usually interpreted on network elements in isolation, and often at timescales that require the representation of embedded policies to be optimized for a specific purpose.

The SUPA information model generalizes common concepts from multiple technology-specific data models, and makes it reusable. Conceptually, SUPA can be used to interface and manage existing and future data models produced by other IETF working groups. In addition, by defining an object-oriented information model with metadata, the characteristics and behavior of data models can be better defined.
4. Security Considerations

Security is a key aspect of any protocol that allows state installation and extracting detailed configuration states of network elements. This places additional security requirements on SUPA (e.g., authorization, and authentication of network services) that needs further investigation. Moreover, policy interpretation can lead to corner cases and side effects that should be carefully examined, e.g., in case policy rules are conflicting with each other.

5. IANA Considerations

This document has no actions for IANA.

1. Overview

This document defines two YANG [RFC6020] [RFC6991] policy data models. The first is a generic policy model that is meant to be extended on an application-specific basis. It is derived from the Generic Policy Information Model (GPIM) defined in [1]. The second is an exemplary extension of the first (generic policy) model, and defines policy rules as event-condition-action tuples. Both models are independent of the level of abstraction of the content and meaning of a policy.

The GPIM defines a common framework as a set of model elements (e.g., classes, attributes, and relationships) that specify a common set of policy management concepts that are independent of the type of policy (e.g., imperative, procedural, declarative, or otherwise). The first YANG data model is a translation of the GPIM to a YANG module. The Eca Policy Rule Information Model (EPRIM), also defined in [1], extends the GPIM to represent policy rules that use the Event-Condition-Action (ECA) paradigm. The second YANG data model maps the EPRIM to YANG. The second YANG data model MAY be used to augment the functionality of the first YANG data model.

2. Conventions Used in This Document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119]. In this document, these words will appear with that interpretation only when in ALL CAPS. Lower case uses of these words are not to be interpreted as carrying [RFC2119] significance.
3. Terminology

This section defines acronyms, terms, and symbology used in the rest of this document.

3.1. Acronyms

- CNF: Conjunctive Normal Form
- DNF: Disjunctive Normal Form
- ECA: Event-Condition-Action
- EPRIM: (SUPA) ECA Policy Rule Information Model
- GPIM: (SUPA) Generic Policy Information Model
- NETCONF: Network Configuration protocol
- OAM&P: Operations, Administration, Management, and Provisioning
- OCL: Object Constraint Language
- OID: Object IDentifier
- SUPA: Simplified Use of Policy Abstractions
- UML: Unified Modeling Language
- URI: Uniform Resource Identifier

3.2. Definitions

- Action: a set of purposeful activities that have a set of associated behavior.

- Boolean Clause: a logical statement that evaluates to either TRUE or FALSE. Also called Boolean Expression.

- Condition: a set of attributes, features, and/or values that are to be compared with a set of known attributes, features, and/or values in order to make a decision. A Condition, when used in the context of a Policy Rule, is used to determine whether or not the set of Actions in that Policy Rule can be executed or not.

- Constraint: A constraint is a limitation or restriction. Constraints may be added to any type of object (e.g., events, conditions, and actions in Policy Rules).

- Constraint Programming: a type of programming that uses constraints to define relations between variables in order to find a feasible (and not necessarily optimal) solution.

- Data Model: a data model is a representation of concepts of interest to an environment in a form that is dependent on data repository, data definition language, query language, implementation language, and protocol (typically one or more of these).

Event: an Event is defined as any important occurrence in time of a change in the system being managed, and/or in the environment of the system being managed. An Event, when used in the context of a Policy Rule, is used to determine whether the condition clause of an imperative Policy Rule can be evaluated or not.

Information Model: an information model is a representation of concepts of interest to an environment in a form that is independent of data repository, data definition language, query language, implementation language, and protocol.

Metadata: is data that provides descriptive and/or prescriptive information about the object(s) to which it is attached.

Policy Rule: A Policy Rule is a set of rules that are used to manage and control the changing or maintaining of the state of one or more managed objects.

3.3. Symbology

The following representation is used to describe YANG data modules defined in this draft.

- Brackets "[" and "]" enclose list keys.
- Abbreviations before data node names: "rw" means configuration data (read-write), and "ro" means state data (read-only).
- Symbols after data node names: "?" means an optional node, "!" means a presence container, and "*" denotes a list and leaf-list.
- Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (":").
- Ellipsis ("...") stands for contents of subtrees that are not shown.

4. Design of the SUPA Policy Data Models

This will be completed in the next version of this draft. Three important points are:

- different policy models have common semantics
- capture those semantics within a common framework (GPIM)
- extend these semantics with a specific ECA example (EPRIM)
5. SUPA Policy Data Model YANG Module

The SUPA YANG data model module is divided into two main parts:

1) a set of containers that represent the objects that make updated a Policy Rule and its Policy Rule Components
2) a set of containers that represent the objects that define and apply metadata to Policy Rules and/or Policy Rule Components

Abstract

This document provides a framework and information model for the definition of northbound interfaces for a security policy controller. The interfaces are based on user-intent instead of vendor-specific or device-centric approaches that would require deep knowledge of vendor products and their security features. The document identifies the common interfaces needed to enforce the user-intent-based policies onto network security functions (NSFs) irrespective of how those functions are realized. The function may be physical or virtual in nature and may be implemented in networking or dedicated appliances.

1.  Introduction

Programming security policies in a network is a fairly complex task and requires very deep knowledge of the vendors’ devices in order to implement a security policy. This has been the biggest challenge for both Service Providers and Enterprise, henceforth known as end-customers, to keep up-to-date with the security of their networks and assets. The challenge is amplified due to virtualization because security appliances come in both physical and virtual forms and are supplied by a variety of vendors who have their own proprietary interfaces to manage and implement the security policies on their devices.
Even if an end-customer deploys a single vendor solution across its entire network, it is difficult to manage security policies due to the complexity of network security features available in the devices. The end-customer may use a vendor-provided management system that gives some abstraction in the form of GUI and helps in provisioning and managing security policies. The single vendor approach is highly restrictive in today’s network as explained below:

- The end-customer cannot rely on a single vendor because one vendor may not be able keep up to date with its security needs.
- The large end-customer may have a presence across different sites and regions and that may mean it is not possible to have a single vendor solution due to technical or business reasons.
- If and when the end-customer migrates from one vendor to another, it is not possible to migrate security policies from one management system to another without complex manual work.
- Due to virtualization within data centers, end-customers are using physical and virtual forms of security functions with a wide variety of vendors, including open source, to control their costs.
- The end-customer might choose various devices in the network (such as routers, switches, firewall devices, and overlay-networks) as enforcement points for security policies for any reason (such as network design simplicity, cost, most-effective place, scale and performance).

In order to provide the end-customer with a solution where they can deploy security policies across different vendors and devices whether physical or virtual, the Interface to Network Security Functions (I2NSF) working group in the IETF is defining a set of northbound interfaces.

This document discusses the requirements for these northbound interfaces and describes a framework and information model so that these interfaces can be easily used by end-customer security administrators without knowledge of specific security devices or features. We refer to this as “user-intent-based interfaces”.

2. Conventions Used in this Document

BSS: Business Support System.

CMDB: Configuration Management Database.

Kumar, et al. Expires January 7, 2017
Controller: Used interchangeably with Service Provider Security Controller or management system throughout this document.

FW: Firewall.

IDS: Intrusion Detection System.

IPS: Intrusion Protection System.

OSS: Operation Support System.

RBAC: Role Based Access Control.

SIEM: Security Information and Event Management.

URL: Universal Resource Locator.

vNSF: Refers to NSF being instantiated on Virtual Machines.

3. Security Provisioning Framework

The IETF I2NSF working group has defined a framework for Interfaces to Network Security Functions that defines following terminology:

Client: A client could be a GUI system used by a security administrator, an OSS/BSS system used by an end-customer, or a security controller system or application in the end-customer’s management system.

Client-Facing Interface: A client-facing interface is an interface used to configure and manage security a framework across the entire network independent of device-specific interface so that same interface can be used for any device from any vendor.

The "Client Facing Interface" ensures that an end-customer can deploy any device from any vendor and still be able to use same consistent interface. In essence, these interfaces give a framework to manage end-customer’s security policies. Henceforth in this document, we "security policy management interface" interchangeably when we refer to these northbound interfaces.
3.1. Deployment Models for Implementing Security Policies

This document describes a framework for security policy management interfaces. This document does not describe a framework for southbound interface: those may be defined in another draft.

Traditionally, medium and larger end-customers deploy management systems to manage their security policies. This approach may not be suitable for modern datacenters that are virtualized and manage their resources using controllers.

There are two different deployment models:

a. Management without an explicit management system for control of devices and NSFs. In this deployment, the security policy controller acts as a NSF policy management system that takes information passed over the northbound policy interface and translates into data on the I2NSF southbound interface. The I2NSF interfaces are implemented by security device/function vendors. This would usually be done by having an I2NSF agent embedded in the security device or NSF. This deployment model is shown in Figure 1.
b. Management with an explicit management system for control of devices and NSFs. This model is similar to the model above except that security policy controller interacts with a dedicated management system which could either proxy I2NSF southbound interfaces or could provide a layer where security devices or...
NSFs do not support an I2NSF agent to process I2NSF southbound interfaces. This deployment model is shown in Figure 2.
Although the deployment models discussed here don’t necessarily affect the northbound security policy interface, they do give an overall context for defining a security policy interface based on abstraction.

### 3.2. Client Perspective on Security Policy Configuration and Management

In order to provide I2NSF northbound interface for security policies to client that are not specific to any vendor, device or feature implementation, it is important that security policies shall be configured and managed from a client’s perspective. We refer to this as the user-intent based model since it is primarily driven by how security administrators view security policies from the deployment perspective.

The client perspective ensures that policy management is not only easy to understand for them (the actual users), but is also independent of vendor, device, and specific implementation which is the foremost goal for a northbound interface.

### 4. Functional Requirements for the Northbound Interface

As mentioned earlier, it is important that the northbound interface be primarily driven by user-intent which is what a client understands well. In order to define this interface, we must understand the requirements and framework used by the security administrator.

A security policy that is based on user-intent is completely agnostic of how this policy is enforced in the end-customer’s network. The security controller may choose to implement such a policy on any device (router, switch, firewall) in a physical or virtual form factor. The security policy controller’s implementation is outside the scope of this document and the I2NSF working group.

At a high level, the objects that are required in order to express and build the security policies fall into the following categories:

- Multi-tenancy and RBAC for policy management
- Policy lifecycle management
The above categories are by no means a complete list and may not be sufficient for all use-cases and all end-customers, but should be a good start for a wide variety of use-cases in both Service Provider networks and Enterprise networks.

The following sections provide further details on the above mentioned security policies categories.

4.1. Multi-Tenancy and RBAC for Policy Management

An end-customer that uses security policies may have internal tenants and would like to have a framework wherein each tenant manages its own security policies to provide isolation across different tenants.

An end-customer may be a cloud service provider with multi-tenant deployments where each tenant is a different organization and must allow complete isolation across different tenants.

The RBAC objects and method needed to build such a framework is defined below.

Policy-Tenant: An entity that owns and manages the security policies.

Policy-User: A user within a Policy-Tenant authorized to manage security policies for that tenant.

Policy-Authorization-Role: A role assigned to a Policy-User that determines whether the user has read-write access, read-only access, or no access for certain resources.

Authentication and Authorization Scheme: There must be a scheme for a Policy-User to be authenticated and authorized to use the policy controller.
4.2. Policy Lifecycle Management

In order to provide more sophisticated security framework, there should be a mechanism to express that a policy becomes dynamically active/enforced or inactive based on either security administrator intervention or an event.

One example of dynamic policy management is when the security administrator pre-configures all the security policies, but the policies get activated/enforced or deactivated based on dynamic threats faced by the end-customer. Basically, a threat event may activate certain inactive policies, and once a new event indicates that the threat has gone away, the policies become inactive again.

The northbound interface should support the following mechanisms for policy enforcement:

Admin-Enforced: The policy, once configured, remains active/enforced until removed by the security administrator.

Time-Enforced: The policy configuration specifies the time profile that determines when policy is activated/enforced.

Event-Enforced: The policy configuration specifies the event profile that determines when policy is activated/enforced.

4.3. Policy Endpoint Groups

Typically, when the security administrator configures a security policy, the intention is to apply this policy to certain subsets of the network. The subsets may be identified based on criteria such as users, devices, and applications. We refer to such a subset of the network as a "Policy Endpoint Group".

One of the biggest challenges for a security administrator is how to make sure that security policies remain effective while constant changes are happening to the "Policy Endpoint Group" for various reasons (e.g., organizational changes). If the policy is created based on static information such as user names, application, or network subnets, then every time that this static information changes policies would need to be updated. For example, if a policy is created that allows access to an application only from the group of Human Resource users (the HR-users group), then each time the HR-users group changes, the policy needs to be updated.

Changes to policy could be highly taxing to the end-customer for various operational reasons. The policy management framework must allow "Policy Endpoint Group" to be dynamic in nature so that changes
to the group (HR-users in our example) automatically result in updates to its content.

We call these dynamic Policy Endpoint Groups "Meta-data Driven Groups". The meta-data is a tag associated with endpoint information such as users, applications, and devices. The mapping from meta-data to dynamic content could come either from standards-based or proprietary tools. The security controller could use any available mechanisms to derive this mapping and to make automatic updates to the policy content if the mapping information changes.

The northbound policy interface must support endpoint groups for user-intent based policy management. The following meta-data driven groups are typically used for configuring security policies:

User-Group: This group identifies a set of users based on a tag or on static information. The tag to user information is dynamically derived from systems such as Active Directory or LDAP. For example, an end-customer may have different user-groups, such as HR-users, Finance-users, Engineering-users, to classify a set of users in each department.

Device-Group: This group identifies a set of devices based on a tag or on static information. The tag to device information is dynamically derived from systems such as CMDB. For example, an end-customer may want to classify all machines running one operating system into one group and machines running another operating system into another group.

Application-Group: This group identifies a set of applications based on a tag or on static information. The tag to application information is dynamically derived from systems such as CMDB. For example, an end-customer may want to classify all applications running in the Legal department into one group and all applications running under a specific operating system into another group.

Location-Group: This group identifies a set of locations based on a tag or on static information. The tag to location information is dynamically derived from systems such as CMDB. For example, an end-customer may want to classify all sites/locations in a geographic region as one group.

4.4. Policy Rules

The security policy rules can be as simple as specifying a match for the user or application specified through "Policy Endpoint Group" and take one of the "Policy Actions" or more complicated rules that
specify how two different "Policy Endpoint Groups" interact with each other. The northbound interface must support mechanisms to allow the following rule matches.

Policy Endpoint Groups: The rule must allow a way to match either a single or a member of a list of "Policy Endpoint Groups".

There must also be a way to express whether a group is a source or a destination so that the security administrator can apply the rule in only one direction of a communication.

There must also be a way to express a match between two "Policy Endpoint Groups" so that a policy can be effective for communication between two groups.

Direction: The rule must allow a way to express whether the security administrator wants to match the "Policy Endpoint Group" as the source or destination. The default should be to match both directions if the direction rule is not specified in the policy.

Threats: The rule should allow the security administrator to express a match for threats that come either in the form of feeds (such as botnet feeds, GeoIP feeds, URL feeds, or feeds from a SIEM) or speciality security appliances.

The threat could be from malware and this requires a way to match for virus signatures or file hashes.

4.5. Policy Actions

The security administrator must be able to configure a variety of actions within a security policy. Typically, security policy specifies a simple action of "deny" or "permit" if a particular rule is matched. Although this may be enough for most of the simple policies, the I2NSF northbound interface must also provide a more comprehensive set of actions so that the interface can be used effectively across various security functions.

Permit: This action means continue processing the next rule or allow the packet to pass if this is the last rule.

Deny: This action means stop further rule processing and drop the packet.

Drop connection: This action means stop further rule processing, drop the packet, and drop connection (for example, by sending a TCP reset).
Log: This action means create a log entry whenever a rule is matched.

Authenticate connection: This action means that whenever a new connection is established it should be authenticated.

Quarantine/Redirect: This action may be relevant for event driven policy where certain events would activate a configured policy that quarantines or redirects certain packet flows.

4.6. Third-Party Integration

The security policies in the end-customer’s network may require the use of specialty devices such as honeypots, behavioral analytics, or SIEM in the network, and may also involve threat feeds, virus signatures, and malicious file hashes as part of comprehensive security policies.

The northbound interface must allow the security administrator to configure these threat sources and any other information to provide integration and fold this into policy management.

4.7. Telemetry Data

One of the most important aspect of security is to have visibility into the networks. As threats become more sophisticated, the security administrator must be able to gather different types of telemetry data from various devices in the network. The collected data could simply be logged or sent to security analysis engines for behavioral analysis and for threat detection.

The northbound interface must allow the security administrator to collect various kinds of data from NSFs. The data source could be syslog, flow records, policy violation records, and other available data.

5. Operational Requirements for the Northbound Interface

5.1. API Version

The northbound interface must support a version number for each RESTful API. This is very important because the client application and the controller application will most likely come from different vendors. Even if the vendor is same, it is hard to imagine that two different applications would be released in lock step.

Without API versioning, it hard to debug and figure out issues if application breaks. Although API versioning does not guarantee that
applications will always work, it helps in debugging if the problem
is caused by an API mismatch.

5.2. API Extensibility

Abstraction and standardization of the northbound interface is of
tremendous value to end-customers as it gives them the flexibility of
deploying any vendors’ NSF. However this might also look like as an
obstacle to innovation.

If an NSF vendor comes up with new feature or functionality that
can’t be expressed through the currently defined northbound
interface, there must be a way to extend existing APIs or to create a
new API that is relevant for that NSF vendor only.

6. IANA Considerations

This document requires no IANA actions. RFC Editor: Please remove
this section before publication.

Abstract

Simplified Use of Policy Abstractions (SUPA) defines a set of rules that define how services are designed, delivered, and operated within an operator’s environment independent of any one particular service or networking device. This document describes the SUPA basic architecture, its elements and interfaces.

1. Introduction

The rapid growth in the variety and importance of traffic flowing over increasingly complex enterprise and service provider network architectures makes the task of network operations and management applications and deploying new services much more difficult. In addition, network operators want to deploy new services quickly and efficiently. Two possible mechanisms for dealing with this growing difficulty are the use of software abstractions to simplify the design and configuration of monitoring and control operations and the use of programmatic control over the configuration and operation of such networks. Policy-based management can be used to combine these two mechanisms into an extensible framework.
Policy rules can be used to express high-level network operator requirements directly, or from a set of management applications, to a network management or element system. The network management or element system can then control the configuration and/or monitoring of network elements and services.

Simplified Use of Policy Abstractions (SUPA) will define a generic policy information model (GPIM) [SUPA-info-model] for use in network operations and management applications. The GPIM defines concepts and terminology needed by policy management independent of the form and content of the policy rule. The ECA Policy Rule Information Model (EPRIM) [SUPA-info-model] extends the GPIM to define how to build policy rules according to the event-condition-action paradigm.

Both the GPIM and the EPRIM are targeted at controlling the configuration and monitoring of network elements throughout the service development and deployment lifecycle. The GPIM and the EPRIM will both be translated into corresponding YANG [RFC6020] modules that define policy concepts, terminology, and rules in a generic and interoperable manner; additional YANG modules may also be defined from the GPIM and/or EPRIM to manage specific functions.

The key benefit of policy management is that it enables different network elements and services to be instructed to behave the same way, even if they are programmed differently. Management applications will benefit from using policy rules that enable scalable and consistent programmatic control over the configuration and monitoring of network elements and services.

2. Framework for Generic Policy-based Management

This section briefly describes the design and operation of the SUPA policy-based management framework.

2.1. Overview

Figure 1 shows a simplified functional architecture of how SUPA is used to define policies for creating network element configuration and monitoring snippets. SUPA uses the GPIM to define a consensual vocabulary that different actors can use to interact with network elements and services. The EPRIM defines a generic structure for imperative policies. The GPIM, as well as the combination of the GPIM and EPRIM, are converted to generic YANG data modules. The IETF produces the modules, and IANA is used to register the module and changes to it.
In one possible approach, SUPA Generic & ECA Policy YANG Data modules together with the Resource and Service YANG data models specified in IETF (which define the specific elements that will be controlled by policies) are used by the Service Interface Logic. This Service Interface Logic creates appropriate input mechanisms for the operator to define policies (e.g., a web form or a script) for creating and managing the network configuration. The operator interacts with the interface, which is then translated to configuration snippets.

Note that YANG models may not exist. In this case, the SUPA generic policy YANG data modules serve as an extensible basis to develop new YANG data models for the Service Interface Logic to create appropriate input mechanisms for the operator to define policies. This transfers the work specified by the Resource and Service YANG data models specified in IETF into the Service Interface Logic, which is then translated to configuration snippets.
Figure 1 is exemplary. The Operator actor shown in Figure 1 can interact with SUPA in other ways not shown in Figure 1. In addition, other actors (e.g., an application developer) that can interact with SUPA are not shown for simplicity.

The EPRIM defines an Event-Condition-Action (ECA) policy as an example of imperative policies. An ECA policy rule is activated when its event clause is true; the condition clause is then evaluated and, if true, signals the execution of one or more actions in the action clause. Imperative policy rules require additional management functions, which are explained in section 2.2 below.

Figure 2 shows a SUPA Policy Model creating and communicating policy rules to two different Network Manager and Network Controller elements.

The Generic Policy Information Model (GPIM) was used to construct policies. The GPIM defines generic policy concepts, as well as two types of policies: ECA policy rules and declarative policy statements.

An ECA policy rule is activated when its event clause is true; the condition clause is then evaluated and, if true, signals the execution of one or more actions in the action clause. This type of policy explicitly defines the current and desired states of the system being managed.

A set of Generic Policy Data Models are then created from the GPIM. These YANG data model policies are then used to control the configuration of network elements that model the service(s) to be managed using policy.
Figure 2 SUPA Policy Model Framework
In Figure 2:
A double-headed arrow with Cs means communication;
A double-headed arrow with Ds means derived from.

The network elements used in this framework are:

SUPA Policy Model: represents one or more policy modules that contain the following entities:

Generic Policy Information Model: a model for defining policy rules that are independent of data repository, data definition, query, and implementation languages, and protocol. This model is abstract and is used for design; it MUST be turned into a data model for implementation.

Generic Policy Data Model: a model of policy rules that are dependent of data repository, data definition, query, and implementation languages, and protocol.

ECA Policy Rule Information Data Model (EPRIM): represents a policy rule as a statement that consists of an event clause, a condition clause, and an action clause. This type of Policy Rule explicitly defines the current and desired states of the system being managed. This model is abstract and is used for design; it MUST be turned into a data model for implementation.

ECA Policy Rule Data Model: a model of policy rules derived from EPRIM, consist of an event clause, a condition clause, and an action clause.

NM/NC: Network Manager / Controller, which represents one or more entities that are able to control the operation and management of a network infrastructure (e.g., a network topology that consists of Network Elements).

Network Resource Data Model: a model of the physical and virtual network topology including the resource attributes (e.g., data rate or latency of links) and operational parameters needed to support service deployment over the network topology. An example of a network resource data model can be found in [ID.draft-contreras-supayang-network-topo].

Network Element (NE), which can interact with local or remote NM/NC in order to exchange information, such as configuration information, policy enforcement capabilities, and network status.
Relationship among Policy, Service and Resource models can be illustrated by the figure below.

```
+---------------+                   +----------------+
|   Policy      |         (1)       |   Service      |
|               |*******************|                |
| ( SUPA )      |                   |(L3SM, ...  )   |
+---------------+                   +----------------+

Figure 3 Relationship among Policy, Service and Resource
```

In Figure 3:
(1) policy relies on and is able to adjust service
(2) policy relies on network ability provided by resource and is able to adjust resource
(3) resource relies on network ability and is able to reserve and consume/occupy resource

2.2. Operation

SUPA can be used to define various types of policies, including policies that affect services and/or the configuration of individual or groups of network elements. SUPA can be used by a centralized and/or distributed set of entities for creating, managing, interacting with, and retiring policy rules.

The SUPA scope is limited to policy information and data models. SUPA will not define network resource data models or network service data models; both are out of scope. Instead, SUPA will make use of network resource data models defined by other WGs or SDOs.

Declarative policies that specify the goals to achieve but not how to achieve those goals (also called "intent-based" policies) are out of scope for the initial phase of SUPA.
2.3. The GPIM and the EPRIM

The GPIM provides a common vocabulary for representing concepts that are common to expressing different types of policy, but which are independent of language, protocol, repository, and level of abstraction.

This enables different policies at different levels of abstraction to form a continuum, where more abstract policies can be translated into more concrete policies, and vice-versa. For example, the information model can be extended by generalizing concepts from an existing data model into the GPIM; the GPIM extensions can then be used by other data models.

The SUPA working group develops models for expressing policy at different levels of abstraction. Specifically, two models are envisioned (both of which are contained in the Generic Policy Information Model block in Figure 1):

1. a generic model (the GPIM) that defines concepts and vocabulary needed by policy management systems independent of the form and content of the policy

2. a more specific model (the EPRIM) that refines the GPIM to specify policy rules in an event-condition-action form

2.4. Creation of Generic YANG Modules

An information model is abstract. As such, it cannot be directly instantiated (i.e., objects cannot be created directly from it). Therefore, both the GPIM, as well as the combination of the GPIM and the EPRIM, are translated to generic YANG modules.

SUPA will provide guidelines for translating the GPIM (or the combination of the GPIM and the EPRIM) into concrete YANG data models that define how to manage and communicate policies between systems. Multiple imperative policy YANG data models may be instantiated from the GPIM (or the combination of the GPIM and the EPRIM). In particular, SUPA will specify a set of YANG data models that will consist of a base policy model for representing policy management concepts independent of the type or structure of a policy, and as well, an extension for defining policy rules according to the ECA paradigm.

The process of developing the GPIM, EPRIM and the derived/translated YANG data models is realized following the sequence shown below. After completing this process and if the implementation of the YANG
data models requires it, the GPIM and EPRIM and the
derived/translated YANG data models are updated and synchronized.

(1)=>(2)=>(3)=>(4)=>(3')=>(2')=>(1')

Where, (1)=GPIM; (2)=EPRIM; (3)=YANG data models; (4)=
Implementation; (3')= update of YANG data models; (2')=update of
EPRIM; (1') = update of GPIM

The YANG module derived from the GPIM contains concepts and
terminology for the common operation and administration of policy-
based systems, as well as an extensible structure for policy rules
of different paradigms. The YANG module derived from the EPRIM
extends the generic nature of the GPIM to represent policies using
an event-condition-action structure.

3. Security Considerations
TBD

4. IANA Considerations
This document has no actions for IANA.

5. Contributors
The following people all contributed to creating this document,
listed in alphabetical order:
TBD.

6. Acknowledgments
This document has benefited from reviews, suggestions, comments and
proposed text provided by the following members, listed in
alphabetical order: Andy Bierman.

Part of the initial draft of this document was picked up from
previous documents, and this section lists the acknowledgements from
them.

From "SUPA Value Proposition" [Klyus2016]
The following people all contributed to creating this document,
listed in alphabetical order:

Liu, et al.  Expires January 8, 2017
Vikram Choudhary, Huawei Technologies
Luis M. Contreras, Telefonica I+D
Dan Romascanu, Avaya
J. Schoenwaelder, Jacobs University, Germany
Qiong Sun, China Telecom
Parviz Yegani, Juniper Networks

This document has benefited from reviews, suggestions, comments and proposed text provided by the following members, listed in alphabetical order: H. Rafiee, J. Saperia and C. Zhou.

The authors of "SUPA Value Proposition" [Klyus2016] were:

Maxim Klyus, Ed., NetCracker
John Strassner, Ed., Huawei Technologies
Will(Shucheng) Liu, Huawei Technologies
Georgios Karagiannis, Huawei Technologies
Jun Bi, Tsinghua University

The initial draft of this document merged one document, and this section lists the acknowledgements from it.

From "Problem Statement for Simplified Use of Policy Abstractions (SUPA)" [Karagiannis2015]

The authors of this draft would like to thank the following persons for the provided valuable feedback and contributions: Diego Lopez, Spencer Dawkins, Jun Bi, Xing Li, Chongfeng Xie, Benoit Claise, Ian Farrer, Marc Blancet, Zhen Cao, Hosnieh Rafiee, Mehmet Ersue, Simon Perreault, Fernando Gont, Jose Saldana, Tom Taylor, Kostas Pentikousis, Juergen Schoenwaelder, John Strassner, Eric Voit, Scott O. Bradner, Marco Liebsch, Scott Cadzow, Marie-Jose Montpetit. Tina Tsou, Will Liu and Jean-Francois Tremblay contributed to an early version of this draft.

The authors of "Problem Statement for Simplified Use of Policy Abstractions (SUPA)" [Karagiannis2015] were:

The authors of this draft would like to thank the following persons for the provided valuable feedback: Diego Lopez, Jose Saldana, Spencer Dawkins, Jun Bi, Xing Li, Chongfeng Xie, Benoit Claise, Ian Farrer, Marc Blancet, Zhen Cao, Hosnieh Rafiee, Mehmet Ersue, Mohamed Boucadair, Jean Francois Tremblay, Tom Taylor, Tina Tsou, Georgios Karagiannis, John Strassner, Raghav Rao, Jing Huang.

Early version of this draft can be found here: https://tools.ietf.org/html/draft-zhou-supap-architecture-00

At the early stage of SUPA, we think quite some issues are left open, it is not so suitable to call this draft as "architecture". We would like to rename it to "framework". Later there may be a dedicated architecture document.

The authors of "The Framework of Simplified Use of Policy Abstractions (SUPA)" [Zhou2015] were:

Cathy Zhou, Huawei Technologies
Luis M. Contreras, Telefonica
Qiong Sun, China Telecom
Parviz Yegani, Juniper
