OSPF Extensions for Advertising/Signaling Geo Location Information
draft-acee-ospf-geo-location-05.txt

Abstract

This document specifies an OSPF Router Information (RI) TLV to advertise the current Geo Coordinates of the OSPF router. For Point-to-Point (P2P) and Point-to-Multi-Point (P2MP) networks, the Geo Coordinates can be used to dynamically computing the cost to neighbors. This is useful both from the standpoint of auto-configuration and situations where the OSPF routers are moving. The Geo Coordinates are also useful for other applications such as Traffic Engineering (TE) and network management.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 21, 2018.

1. Introduction

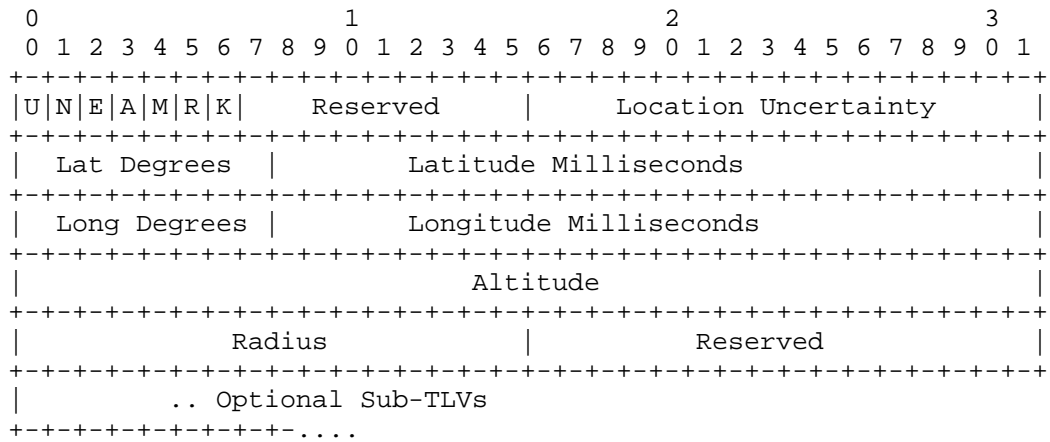

This document specifies an OSPF Router Information (RI) [OSPF-RI] TLV to advertise the current Geo Coordinates of the OSPF router. For Point-to-Point (P2P) and Point-to-Multi-Point (P2MP) networks, the Geo Coordinates can be used to dynamically computing the cost to neighbors. This is useful both from the standpoint of auto-configuration and situations where the OSPF routers are moving. The Geo Coordinates are also useful for other applications such as Traffic Engineering (TE) and network management.

1.1. Requirements Notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC-KEYWORDS].

2. OSPF Geo Coordinates TLV

The Geo Coordinates TLV can be used to advertise the current location of an OSPFv2 [OSPF] or OSPFv3 [OSPFV3] router using the OSPF Router Information LSA [OSPF-RI]. The OSPF Router Information LSA can be advertised in both link-scoped and area or AS scoped RI LSAs. The fields specify the location of the OSPF router using the WGS-84 (World Geodetic System) reference coordinate system [WGS84]. The value of the Geo Coordinates TLV consists of the following fields:

Where:

- U-bit: If the U-bit is set, it indicates that the "Location Uncertainty" field is specified. If the U-bit is clear, it indicates the "Location Uncertainty" field is unspecified.
- N-bit: If the N-bit is set, it indicates the Latitude is north relative to the Equator. If the N-bit is clear, it indicates the Latitude is south of the Equator.
- E-bit: If the E-bit is set, it indicates the Longitude is east of the Prime Meridian. If the E-bit is clear, it indicates the Longitude is west of the Prime Meridian.
- A-bit: If the A-bit is set, it indicates the "Altitude" field is specified. If the A-bit is clear, it indicates the "Altitude" field is unspecified.
- M-bit: If the M-bit is set, it indicates the "Altitude" is specified in meters. If the M-bit is clear, it indicates the "Altitude" is in centimeters.
- R-bit: If the R-bit is set, it indicates the "Radius" field is specified and the encoding is for a circular area. If the R-bit is clear, it indicates the "Radius" field is unspecified and the encoding is for a single point.
- K-bit: If the K-bit is set, it indicates the "Radius" is specified in kilometers. If the K-bit is clear, it indicates the "Radius" is in meters.

- Reserved: These bits are reserved. They SHOULD be set to 0 when sending protocol packets and MUST be ignored when receiving protocol packets.
- Location Uncertainty: Unsigned 16-bit integer indicating the number of centimeters of uncertainty for the location.
- Latitude Degrees: Unsigned 8-bit integer with a range of 0 - 90 degrees north or south of the Equator (northern or southern hemisphere, respectively).
- Latitude Milliseconds: Unsigned 24-bit integer with a range of 0 - 3,599,999 (i.e., less than 60 minutes).
- Longitude Degrees: Unsigned 8-bit integer with a range of 0 - 180 degrees east or west of the Prime Meridian.
- Longitude Milliseconds: Unsigned 24-bit integer with a range of 0 - 3,599,999 (i.e., less than 60 minutes).
- Altitude: Signed 32-bit integer containing the Height relative to sea level in centimeters or meters. A negative height indicates that the location is below sea level.
- Radius: Unsigned 16-bit integer containing the radius of a circle centered at the specified coordinates. The radius is specified in meters unless the K-bit is specified indicating specification in kilometers. If the radius is specified, the geo-coordinates specify the entire area of the circle defined by the radius and center point. While the use cases herein do not make use of this field, future use cases may.
- Optional Sub-TLVs: No additional Sub-TLVs are defined in this document.

OSPF Geo Coordinates TLV

3. Link Advertisement of the OSPF Geo-Coordinates

When the Geo Coordinates are used for cost computation, the coordinates need to be advertised on the link using the encoding specified in Section 2. For this application, a link-scoped OSPF Router Information (RI) [OSPF-RI] is advertised on each link where geo-location cost computation is utilized.

When an OSPF router receives the Geo Coordinates TLV in a link-scoped OSPF RI LSA from an adjacent neighbor, it can be used to calculate the physical distance to neighbor. For P2P and P2MP networks, this distance can be used to dynamically compute the cost of the link to that neighbor. The mapping of the distance to advertised cost is not specified in this document. However, all OSPF routers in the domain SHOULD use the same algorithm. Computation of cost based on physical distance can be useful both for autoconfiguration of these networks types and dynamic cost computation when the routers are moving.

The Geo location information can be statically provisioned or dynamically acquired from a GPS capable device on the OSPF Router.

4. OSPFv2 Router Information (RI) Opaque LSA

The OSPF Geo Coordinates TLV may optionally be advertised in the OSPF Router Information (RI) LSA [OSPF-RI]. It then may be used for applications such as traffic engineering (TE) and network management (e.g., the Find-My-Router application). The details of such applications are beyond the scope of this document.

5. Security Considerations

Since the Geo Location coordinates provide the exact location of the OSPF router, disclosure will make the OSPF router more susceptible to physical attacks. In situations where this is a concern (e.g., military applications), confidentiality should be provided either through a secure tunnel (e.g., [IP-ESP]) or protocol encryption [OSPFV3-AUTH].

Additionally, in some situations, the topology of the network is considered proprietary information. With the Geo Location coordinates, the physical topology, as well as the IP topology, can be discerned from the OSPF Router Information (RI) LSA. In these situations, confidentiality should be assured.

Security considerations for the base OSPF protocol are covered in [OSPF] and [OSPFV3].

6. Privacy Considerations

If the location of an OSPF router advertising geo location coordinates as described herein can be directly correlated to an individual, individuals, or an organization, the location of that router should be considered sensitive and OSPF RI LSAs containing such geo coordinates should be advertised confidentially as described in Section 5. Additionally, OSPF network management facilities may

require added authorization to view the contents of OSPF RI LSAs containing geo-Location TLVs. Refer to [PRIVACY] for more information.

The Uncertainty and Confidence metrics for geo-location information as described in [GEO-PIDF-LO] are not included in the Geo Coordinates TLV. In a future document, these may be considered for inclusion with additional Geo Location Sub-TLVs dependent on both on requirements and adoption of [GEO-PIDF-LO].

7. IANA Considerations

The document will require the following IANA actions:

1. A Router Information TLV type for the Geo Location TLV will be allocated from the OSPF Router Information (RI) TLVs registry.

LSA Flushing Problem Mitigation in OSPF Networks
draft-dong-ospf-flush-mitigation-00

Abstract

In OSPF protocol, LSAs with the LS age at MaxAge are not used in routing table calculation and MUST be flushed in the network. In some cases, the flushing of OSPF MaxAge LSAs may cause flooding storm of OSPF packets and severely impact network stability and the services provided by the network. This document specifies a backward compatible mechanism to mitigate the impact of MaxAge LSA flushing in OSPF networks.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

1. Introduction

In OSPF protocol [RFC2328], Link State Updates (LSAs) are exchanged in Link State Update (LSU) packets to achieve link-state database (LSDB) synchronization and consistent route calculation. LSAs with the LS age at MaxAge are not used in routing table calculation and MUST be flushed in the network. In some cases, the flushing of MaxAge LSAs can cause flooding storm of OSPF packets and severely impact network stability and the services provided by the network. [I-D.dong-ospf-maxage-flush-problem-statement] analyzes the problem of MaxAge LSA flushing, and gives the requirements on potential solutions.

This document proposes a backward compatible mechanism to mitigate the impacts of MaxAge LSA flushing in OSPF networks.

2. Proposed Solution

In normal cases, the flushing of router-LSA indicates that the originator of the LSA is no longer reachable in the network and is unable to refresh the LSA. The flushing of other types of LSAs indicate the routing information carried in the LSAs is no longer applicable. Since usually the removal of a node is a significant change to the network and can also be informed by the update of LSAs of its adjacent routers, the flushing of router-LSA MUST be processed carefully to avoid unnecessary routing churns caused by improper LSA flushing.

The proposed solution aims to distinguish persistent LSA flushing from normal LSA flushing, so that the impact of persistent flushing can be alleviated without slowing down normal route convergence. Specifically, the flushing of router-LSA and the subsequent flushing of LSAs belonging to the same originator are further examined. During the examination time, the old instance of the LSAs and the MaxAge LSAs are kept in LSDB and the route recalculation is postponed.

Two types of timers are used in this solution:

- o T1: the examination time of the suspicious persistent LSA flushing of a particular router. When a MaxAge router-LSA of a particular router is received, timer T1 fires and the originator of the router-LSA is marked as in Restrain state. The value of timer T1 is configurable, and the RECOMMENDED value is 1800 seconds.
- o T2: the examination time of a received MaxAge LSA, the originator of which is currently in Restrain state. When a Maxage LSA is received and the originator of the LSA is in Restrain state, timer T2 fires and the old instance of the LSA is still in use, which means the Maxage LSA does not trigger route recalculation. The value of timer T2 is configurable, and the RECOMMENDED value is 10 seconds.

The detailed procedures are described as follows :

- a. When a MaxAge router-LSA is received,
 - o If the originator of the LSA is not in Restrain state, mark the originator of the LSA as in Restrain state, timer T1 is started for that router, and timer T2 is started for the router-LSA. The MaxAge LSA is flushed further in the newtork, while the old instance of the LSA is still in use in route calculation until T2 expires.

- o If the originator of the LSA is already in Restrain state, then T1 is restarted for that router. If timer T2 does not exist for this LSA, timer T2 is started for the LSA.
- b. When a MaxAge LSA with LSA-type other than router LSA is received,
 - o If the originator of the LSA is in Restrain state, timer T2 is started for the LSA. The MaxAge LSA is flushed further in the network, while the old instance of the LSA is in use in route calculation.
 - o If the originator of the LSA is not in Restrain state, the processing is according to [RFC2328].
 - c. When a newer LSA instance originated by a router in Restrain state is received,
 - o If timer T2 for this LSA exists, the newer instance replaces the old LSA instance in link-state database and triggers route recalculation, timer T2 for this LSA is stopped.
 - o If timer T2 for this LSA does not exist, the processing is according to [RFC2328].
 - d. When timer T2 for a particular LSA expires, the MaxAge LSA triggers route recalculation and is removed from link-state database.
 - e. When timer T1 for a particular router expires, the router is marked as in normal state.

3. Deployment Considerations

While it is RECOMMENDED that the proposed mechanism deployed on all the routers in the same OSPF network, this mechanism can also be deployed into the network incrementally.

4. IANA Considerations

This document makes no request of IANA.

Note to RFC Editor: this section may be removed on publication as an RFC.

OSPF LSA Flushing Problem Statement
draft-dong-ospf-maxage-flush-problem-statement-01

Abstract

In OSPF protocol, Link State Advertisements (LSAs) are exchanged in Link State Update (LSU) packets to achieve link state database (LSDB) synchronization and consistent route calculation. OSPF protocol specifies several scenarios in which an LSA is flushed with the LS age field set to MaxAge. In some cases, the flushing of MaxAge LSAs may cause flooding storm of OSPF packets and severely impact the services provided by the network.

This document describes the problem of OSPF LSA flushing, and ask for solutions to solve this problem.

1. Introduction

In OSPF protocol [RFC2328], Link State Updates (LSAs) are exchanged in Link State Update (LSU) packets to achieve link state database (LSDB) synchronization and consistent route calculation. OSPF specifies several scenarios in which an LSA is flushed with the LS age field set to MaxAge. In some cases, the flushing of MaxAge LSAs may cause flooding storm of OSPF packets and severely impact the services in the network. Since the MaxAge LSA may be flushed by any OSPF router, usually it would take a long time for troubleshooting and could cause huge damage to both the network provider and its customers.

2. Typical Scenarios of LSA Flushing

[RFC2328] specifies several scenarios in which an LSA should be flushed with the LS age field set to MaxAge. Under normal circumstances, the LSA flushing happens when the LS age of an LSA naturally reaches MaxAge, this can be done by any OSPF router. Since OSPF router would generate a new instance of the self-originated LSA when its LS age reaches LSRefreshTime, which is usually the half of the value of MaxAge, the naturally aging to MaxAge case would only happen when the originator of the LSA is not reachable in the network and cannot refresh the LSA.

Another case of LSA flushing is "Premature aging", which is to set the LS age of a self-originated LSA to MaxAge and then flood the LSA. Premature aging is used when the self-originated LSA's sequence number field is about to wrap, or all the external routes previously advertised by the LSA are no longer reachable. Premature aging and flushing of LSA can also happen when a router is changed from the Designated Router (DR) to a non-DR, or in some rare cases the router's Router ID is changed.

Field experience has shown several circumstances where MaxAge LSA flushing may be generated by the misbehaved router in the network. For example, the LS age may be corrupted to reach the MaxAge much earlier than normally expected. This is difficult to detect with the existing OSPF checksum mechanism, as the LS age field is excluded from the checksum calculation of LSA. Besides, OSPF cryptographic authentication can not detect the corruption of the LS age field if it happens before the LSA is assembled to LSU packet.

3. Consequence of LSA Flushing

While MaxAge LSA flushing is important for fast convergence and the consistency of the Link-State DataBase (LSDB) of all OSPF routers, as shown in several accidents happened in the production network, improper LSA flushing can have severe impact to the network and the services provided by the network. This section evaluates the impacts of MaxAge LSA flushing.

According to section 14 of [RFC2328], the MaxAge LSA can be flushed by any router, no matter whether this LSA is self-originated or not. According to the flooding scope of the LSA, this MaxAge LSA would be flooded either in the whole routing domain or in the specific area. On all the routers receiving this MaxAge LSA, this would cause the old LSA instance being replaced, and consequently triggers route calculation and installation. When the MaxAge LSA is received by the originating router of this LSA, the originating router would increase the LSA's LS sequence number one past the received LS sequence

number, and originate a new instance of the LSA. If the LSA flushing is due to systematic problem and cannot recover automatically, this flooding and processing would last forever, which severely impacts network reachability and stability. Since OSPF is the fundamental protocol to build the infrastructure for other protocols such as BGP, LDP, etc., and various services provided by the network, it will cause huge damage to both the network provider and its customers.

As the MaxAge LSA may be flushed by any OSPF router, usually it would take a long time for troubleshooting to locate the misbehaved router in the network, and during this time the LSA flushing could have caused huge damage to both the network provider and its customers.

4. Requirements on Potential Solutions

Considering the importance of OSPF protocol to the networks and the services carried in the networks, and the potential severe impact of MaxAge LSA flooding, this document calls for solutions to protect against or mitigate the impact of improper MaxAge LSA flushing.

The potential solutions can be classified into two categories, and the requirements are provided in following sections respectively.

4.1. Solution for Problem Localization

Since OSPF allows the flushing of non-self originated LSAs, for troubleshooting and problem localization, some mechanism to identify the misbehaved router quickly is needed. If the improper MaxAge LSA flushing is caused by systematic problem, operators would need to locate the misbehaved router and shut it down to stop the flooding storm.

[RFC6232] proposes to add the Purge Originator Identification (POI) TLV into IS-IS Purge LSPs to identify the originator of IS-IS Purges. Although a similar TLV may be added into the OSPF extended LSAs as defined in [RFC7684] and [I-D.ietf-ospf-ospfv3-lsa-extend], the structure of the legacy OSPF LSAs as defined in [RFC2328] is not TLV-based and such mechanism does not apply. Some problem localization solution which is backward compatible and applicable to all the OSPF LSAs would be preferred.

4.2. Solution for Impact Mitigation

Since the flooding storm caused by improper LSA flushing can have severe impact to network stability and the services provided by the network, it is important to alleviate such impact even before the root cause or the misbehaved router can be identified. In addition, some problem localization mechanisms may rely on the availability of

the network, which means the impact mitigation mechanism is necessary to ensure that the problem localization mechanisms do work when severe flooding storm caused by LSA flushing happens in the network.

It is important that the impact mitigation solution is backward compatible and can support incremental deployment. Preferably, the mitigation solution should not delay the route convergence triggered by normal LSA flushing.

5. IANA Considerations

This document makes no request of IANA.

Note to RFC Editor: this section may be removed on publication as an RFC.

6. Security Considerations

This document describes the problem of MaxAge LSA flushing, which in some cases is due to the lack of integrity protection of the LS age field. The LS age field may be altered as a result of software or hardware problem, such modification cannot be detected by LSA checksum nor OSPF packet cryptographic authentication. LSA flushing could have severe impact on network stability and the services provided by the network. This may be considered as a security vulnerability.

Advertising TE protocols in OSPF
draft-hegde-ospf-advertising-te-protocols-01

Abstract

This document defines a mechanism to indicate which traffic engineering protocols are enabled on a link in OSPF. It does so by introducing a new Traffic-Engineering Protocol sub-TLV for the Link TLV in the OSPFv2 TE Opaque LSA. This document also describes mechanisms to address backward compatibility issues for routers that have not yet been upgraded to software that understands this new sub-TLV.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 17, 2018.

1. Introduction

OSPF extensions for traffic engineering are specified in [RFC3630]. [RFC3630] defines several link attributes such as administrative group, maximum link bandwidth, and shared risk link groups (SRLGs) which can be used by traffic engineering applications. Additional link attributes for traffic engineering have subsequently been defined in other documents as well. Most recently [RFC7471] defined link attributes for delay, loss, and measured bandwidth utilization. All of the TE link attributes specified in [RFC3630] and [RFC7471] are carried in sub-TLVs in the Link TLV of the TE Opaque LSA.

The primary consumers of these traffic engineering link attributes have been RSVP-based applications that use the advertised link attributes to compute paths which will subsequently be signalled using RSVP-TE. However, these traffic engineering link attributes

have also been used by other applications, such as IP/LDP fast-reroute using loop-free alternates as described in [RFC7916]. In the future, it is likely that traffic engineering applications based on Segment Routing [I-D.ietf-spring-segment-routing] will also use these link attributes.

Existing OSPF standards do not provide a mechanism to explicitly indicate whether or not RSVP has been enabled on a link. In general, implementations have used the presence of the Link TLV in the TE Opaque LSA to infer that RSVP is enabled on a link.

This document defines a standard way to indicate whether or not RSVP, segment routing, or another future protocol is enabled on a link. In this way, implementations will not have to infer whether or not RSVP is enabled based on the presence of different sub-TLVs, but can use the explicit indication. When network operators want to use a non-RSVP traffic engineering application (such as IP/LDP FRR or segment routing), they will be able to advertise traffic engineer sub-TLVs and explicitly indicate what traffic engineering protocols are enabled on a link.

2. Motivation

The motivation of this document is to provide a mechanism to advertise TE attributes for current and future applications without ambiguity. The following objectives help to accomplish this in a range of deployment scenarios.

1. Advertise TE attributes for the link for variety of applications.
2. Allow the solution to be backward compatible so that nodes that do not understand the new advertisement do not cause issues for existing RSVP deployment.
3. Allow the solution to be extensible for any new applications that need to look at TE attributes.
4. Allow the TE protocol enabled on a link to be communicated unambiguously.
5. The solution should try to limit any increases to the quantity and size of link state advertisements.

2.1. Explicit and unambiguous indication of TE protocol

Communicating unambiguously which TE protocol is enabled on a link is important to be able to share this information with other consumers through other protocols, aside from just the IGP. For example, for a

network running both RSVP-TE and SR, it will be useful to communicate which TE protocols are enabled on which links via BGP-LS [RFC7752] to a central controller. Typically, BGP-LS relies on the IGP to distribute IGP topology and traffic engineering information so that only a few BGP-LS sessions with the central controller are needed. In order for a router running a BGP-LS session to a central controller to correctly communicate what TE protocols are enabled on the links in the IGP domain, that information first needs to be communicated unambiguously within the IGP itself.

2.2. Limit increases in link state advertisements

Over the years, the size of the networks running OSPF has grown both in terms of the total number of nodes as well as the number of links interconnecting those nodes. OSPF has proven to be quite scalable. With the advent of cloud scale computing, we expect the demands placed on OSPF by network operators to continue to grow as networks become larger and more richly interconnected. If we expect OSPF to continue to scale to meet this challenge, then as we evolve OSPF, we should be careful to limit the increases in both the quantity and size of link state advertisements to the amount necessary to solve the problem at hand. The solution described in this draft attempts to do that.

3. Solution

3.1. Traffic-engineering protocol sub-TLV

A new Traffic-Engineering Protocol sub-TLV is added to the Link TLV in the OSPFv2 TE Opaque LSA. The Traffic-Engineering Protocol sub-TLV indicates the protocols enabled on the link. The sub-TLV has flags in the value field to indicate the protocol enabled on the link. The length field is variable to allow the flags field to grow for future requirements.

Figure 1: Traffic-Engineering Protocol sub-TLV

Type : TBA (suggested value 40)

Length: variable (in bytes)

Value: The value field consists of bits indicating the protocols enabled on the link. This document defines the two protocol values below.

Value	Protocol Name
0x01	RSVP
0x02	Segment Routing

Figure 2: Flags for the protocols

The RSVP flag is set to one to indicate that RSVP-TE is enabled on a link. The RSVP flag is set to zero to indicate that RSVP-TE is not enabled on a link.

The Segment Routing flag is set to one to indicate that Segment Routing is enabled on a link. The Segment Routing flag is set to zero to indicate that Segment Routing is not enabled on a link.

All undefined flags MUST be set to zero on transmit and ignored on receipt.

An implementation that supports the TE Protocol sub-TLV and sends the Link TLV MUST advertise the TE protocol sub-TLV in the Link TLV, even when both the RSVP and SR flags are set to zero. In other words, whenever the TE protocol sub-TLV is supported, it MUST be sent, even if no TE protocols are enabled on the link. This allows a receiving router to determine whether or not the sending router is capable of sending the TE Protocol sub-TLV.

A router supporting the TE protocol sub-TLV which receives an advertisement for a link containing the Link TLV with the TE protocol sub-TLV present SHOULD respect the values of the flags in the TE protocol sub-TLV. The receiving router SHOULD only consider links with a given TE protocol enabled for inclusion in a path using that TE protocol. Conversely, links for which the TE protocol sub-TLV is present, but for which the TE protocol flag is not set to one, SHOULD NOT be included in any TE CSPF computations on the receiving router for the protocol in question.

However, if the SR protocol flag is set to zero on a link but the adjacency-sids are advertised for that link, applications MAY use the adjacency-sid for other purposes, for example OAM.

The ability for a receiving router to determine whether or not the sending router is capable of sending the TE protocol sub-TLV is also used for backward compatibility as described in Section 4.

An implementation that supports the TE protocol sub-TLV SHOULD be able to advertise TE attribute sub-TLVs without enabling RSVP-TE signalling on the link.

4. Backward compatibility

Routers running older software that do not understand the new Traffic-Engineering protocol sub-TLV will continue to interpret the presence of the Link TLV in the TE Opaque LSA to mean that RSVP is enabled a link. A network operator may not want to or be able to upgrade all routers in the domain at the same time. There are two backward compatibility scenarios to consider depending on whether the router that doesn't understand the new TE protocol sub-TLV is an RSVP-TE ingress router or an RSVP-TE transit router.

4.1. Scenario with upgraded RSVP-TE transit router but RSVP-TE ingress router not upgraded

An upgraded RSVP-TE transit router is able to explicitly indicate that RSVP is not enabled on a link by advertising the TE protocol sub-TLV with the RSVP flag set to zero. However, an RSVP-TE ingress router that has not been upgraded to understand the new TE protocol sub-TLV will not understand that RSVP-TE is not enabled on the link, and may include the link on a path computed for RSVP-TE. When the network tries to signal an explicit path LSP using RSVP-TE through that link, it will fail. In order to avoid this scenario, an operator can use the mechanism described below.

For this scenario, the basic idea is to use the existing administrative group link attribute as a means of preventing existing RSVP implementations from using a link. The network operator defines an administrative group to mean that RSVP is not enabled on a link. We refer to this admin group the RSVP-not-enabled admin group. If the operator needs to advertise a TE sub-TLV (maximum link bandwidth, for example) on a link, but doesn't want to enable RSVP on that link, then the operator also advertises the RSVP-not-enabled admin group on that link. The operator can then use existing mechanisms to exclude links advertising the RSVP-not-enabled admin group from the constrained shortest path first (CSPF) computation used by RSVP. This will prevent RSVP implementations from attempting to signal

RSVP-TE LSPs across links that do not have RSVP enabled. Once the entire network domain is upgraded to understand the TE protocol sub-TLV in this draft, the configuration involving the RSVP-not-enabled admin group is no longer needed for this network.

To be clear, the RSVP-not-enabled admin group is an arbitrary admin group chosen by a network operator for this purpose. It is not a value that would need to be standardized.

4.2. Scenario with upgraded RSVP-TE ingress router but RSVP-TE transit router not upgraded

The other scenario to consider is when the RSVP-TE ingress router has been upgraded to understand the TE protocol sub-TLV, but the RSVP-TE transit router has not. In this case, the transit router has not been upgraded, so it is not yet capable of sending the TE protocol sub-TLV. If the transit router has RSVP-TE enabled on a link, we would like for the RSVP-TE ingress router to still be able to use the link for RSVP-TE paths. While it is possible to describe a solution for this scenario that makes use of administrative groups, we describe a simpler solution below.

The solution for this scenario relies on the following observation. If the RSVP-TE ingress router can understand that the transit router is not capable of sending the TE protocol sub-TLV, then it can continue inferring whether or not RSVP-TE is enabled on the transit router links based on the presence of the Link TLV in the TE Opaque LSA, just as it does today.

To accomplish this, we require an upgraded router to send the TE protocol sub-TLV if it sends the OSPF TE Link TLV, even when both the RSVP and SR flags are set to zero. In other words, whenever the TE protocol sub-TLV is supported, it MUST be sent, even if no TE protocols are enabled on the link. see Section 3. This allows the receiving router to interpret the absence of the TE-protocol sub-TLV in the OSPF TE Link TLV to mean that the sending router has not been upgraded. This allows the upgraded RSVP-TE ingress router to distinguish between transit routers that have been upgraded and those that haven't. When the transit router has been upgraded, then the RSVP-TE ingress router uses the information in the TE protocol sub-TLV. When the transit router has not been upgraded, then RSVP-TE ingress router continues to infer whether or not RSVP-TE is enabled on the transit router links based on the presence of TE sub-TLVs, just as it does today. The solution for this scenario requires no configuration on the part of network operators.

4.3. Need for a long term solution

The use of the administrative group link attribute to prevent an RSVP-TE ingress router from computing a path using a given link is an effective short term workaround to allow networks to incrementally upgrade the routers to software that understands the new TE-protocol sub-TLV. One might also consider a long term solution based solely on the use of operator-defined administrative groups to communicate the TE protocol enabled on a link. However, we do not consider this workaround to be an effective long term solution because it relies on operator configuration that would have to be maintained in the long term. As discussed in Section 2, continuing to have to infer which TE protocol is enabled on a link would also limit our ability to communicate this information unambiguously in an interoperable manner for use by other applications such as central controllers.

4.4. Interaction with the Extended Link Opaque LSA

The Extended Link TLV and the Extended Link Opaque LSA were introduced in [RFC7684] with the initial purpose of associating Adjacency SIDs with links for segment routing. A pure segment routing deployment that does not make use of any of the traffic engineering attributes carried in the Link TLV in the TE Opaque LSA does not need to advertise the Link TLV in the TE Opaque LSA. It only needs to advertise Extended Link TLV in the Extended Link Opaque LSA for the link. If the operator wants to make use of any traffic engineering attributes defined for the Link TLV in the TE Opaque LSA, then the routers in the network need to advertise the Link TLV in the TE Opaque LSA to carry the TE attributes as well the Extended Link TLV in the Extended Link Opaque LSA to carry the Adjacency SIDs.

5. Security Considerations

This document does not introduce any further security issues other than those discussed in [RFC3630].

6. IANA Considerations

This specification updates one OSPF registry:

The Types for sub-TLVs of the TE Link TLV Registry

- i) Traffic-engineering Protocol sub-tlv = Suggested value 35

OSPFv3 Extensions for Segment Routing
draft-ietf-ospf-ospfv3-segment-routing-extensions-23

Abstract

Segment Routing (SR) allows a flexible definition of end-to-end paths within IGP topologies by encoding paths as sequences of topological sub-paths, called "segments". These segments are advertised by the link-state routing protocols (IS-IS and OSPF).

This draft describes the OSPFv3 extensions required for Segment Routing with MPLS data plane.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

1. Introduction

Segment Routing (SR) allows a flexible definition of end-to-end paths within IGP topologies by encoding paths as sequences of topological sub-paths, called "segments". These segments are advertised by the link-state routing protocols (IS-IS and OSPF). Prefix segments represent an ECMP-aware shortest-path to a prefix (or a node), as per the state of the IGP topology. Adjacency segments represent a hop over a specific adjacency between two nodes in the IGP. A prefix segment is typically a multi-hop path while an adjacency segment, in most cases, is a one-hop path. SR's control-plane can be applied to both IPv6 and MPLS data-planes, and does not require any additional signalling (other than IGP extensions). The IPv6 data plane is out of the scope of this specification - OSPFv3 extension for SR with IPv6 data plane will be specified in a separate document. When used in MPLS networks, SR paths do not require any LDP or RSVP-TE signalling. However, SR can interoperate in the presence of LSPs established with RSVP or LDP.

This draft describes the OSPFv3 extensions required for Segment Routing with MPLS data plane.

Segment Routing architecture is described in [RFC8402].

Segment Routing use cases are described in [RFC7855].

2. Terminology

This section lists some of the terminology used in this document:

ABR - Area Border Router

Adj-SID - Adjacency Segment Identifier

AS - Autonomous System

ASBR - Autonomous System Boundary Router

DR - Designated Router

IS-IS - Intermediate System to Intermediate System

LDP - Label Distribution Protocol

LSP - Label Switched Path

MPLS - Multi Protocol Label Switching

- OSPF - Open Shortest Path First
- SPF - Shortest Path First
- RSVP - Resource Reservation Protocol
- SID - Segment Identifier
- SR - Segment Routing
- SRGB - Segment Routing Global Block
- SRLB - Segment Routing Local Block
- SRMS - Segment Routing Mapping Server
- TLV - Type Length Value

3. Segment Routing Identifiers

Segment Routing defines various types of Segment Identifiers (SIDs): Prefix-SID, Adjacency-SID, and LAN Adjacency SID.

3.1. SID/Label Sub-TLV

The SID/Label Sub-TLV appears in multiple TLVs or Sub-TLVs defined later in this document. It is used to advertise the SID or label associated with a prefix or adjacency. The SID/Label Sub-TLV has following format:

where:

Type: 7

Length: Either 3 or 4 octets

SID/Label: If length is set to 3, then the 20 rightmost bits represent a label. If length is set to 4, then the value represents a 32-bit SID.

The receiving router MUST ignore the SID/Label Sub-TLV if the length is other than 3 or 4.

4. Segment Routing Capabilities

Segment Routing requires some additional router capabilities to be advertised to other routers in the area.

These SR capabilities are advertised in the OSPFv3 Router Information Opaque LSA (defined in [RFC7770]) and specified in [I-D.ietf-ospf-segment-routing-extensions].

5. OSPFv3 Extended Prefix Range TLV

In some cases it is useful to advertise attributes for a range of prefixes in a single advertisement. The Segment Routing Mapping Server, which is described in [I-D.ietf-spring-segment-routing-ldp-interop], is an example of where SIDs for multiple prefixes can be advertised. To optimize such advertisement in case of multiple prefixes from a contiguous address range, OSPFv3 Extended Prefix Range TLV is defined."

The OSPFv3 Extended Prefix Range TLV is a top-level TLV of the following LSAs defined in [RFC8362]:

E-Intra-Area-Prefix-LSA

E-Inter-Area-Prefix-LSA

E-AS-External-LSA

E-Type-7-LSA

Multiple OSPFv3 Extended Prefix Range TLVs MAY be advertised in each LSA mentioned above. The OSPFv3 Extended Prefix Range TLV has the following format:

where:

Type: 9

Length: Variable, in octets, dependent on Sub-TLVs.

Prefix length: Length of prefix in bits.

AF: Address family for the prefix.

AF: 0 - IPv4 unicast

AF: 1 - IPv6 unicast

Range size: Represents the number of prefixes that are covered by the advertisement. The Range Size MUST NOT exceed the number of prefixes that could be satisfied by the prefix length without including:

Addresses from the IPv4 multicast address range (224.0.0.0/3), if the AF is IPv4 unicast

Addresses other than the IPv6 unicast addresses, if the AF is IPv6 unicast

Flags: Reserved. MUST be zero when sent and are ignored when received.

Reserved: SHOULD be set to 0 on transmission and MUST be ignored on reception.

Address Prefix:

For the address family IPv4 unicast, the prefix itself is encoded as a 32-bit value. The default route is represented by a prefix of length 0.

For the address family IPv6 unicast, the prefix, encoded as an even multiple of 32-bit words, padded with zeroed bits as necessary. This encoding consumes $((\text{PrefixLength} + 31) / 32)$ 32-bit words.

Prefix encoding for other address families is beyond the scope of this specification. Prefix encoding for other address families can be defined in the future standard-track IETF specifications.

The range represents the contiguous set of prefixes with the same prefix length as specified by the Prefix Length field. The set starts with the prefix that is specified by the Address Prefix field. The number of prefixes in the range is equal to the Range size.

If the OSPFv3 Extended Prefix Range TLVs advertising the exact same range appears in multiple LSAs of the same type, originated by the same OSPFv3 router, the LSA with the numerically smallest Instance ID MUST be used and subsequent instances of the OSPFv3 Extended Prefix Range TLVs MUST be ignored.

6. Prefix SID Sub-TLV

The Prefix SID Sub-TLV is a Sub-TLV of the following OSPFv3 TLVs as defined in [RFC8362] and in Section 5:

Intra-Area Prefix TLV

Inter-Area Prefix TLV

External Prefix TLV

OSPFv3 Extended Prefix Range TLV

It MAY appear more than once in the parent TLV and has the following format:

where:

Type: 4

Length: 7 or 8 octets, dependent on the V-flag

Flags: Single octet field. The following flags are defined:

where:

NP-Flag: No-PHP flag. If set, then the penultimate hop MUST NOT pop the Prefix-SID before delivering packets to the node that advertised the Prefix-SID.

M-Flag: Mapping Server Flag. If set, the SID was advertised by a Segment Routing Mapping Server as described in [I-D.ietf-spring-segment-routing-ldp-interop].

E-Flag: Explicit-Null Flag. If set, any upstream neighbor of the Prefix-SID originator MUST replace the Prefix-SID with the Explicit-NULL label (0 for IPv4, 2 for IPv6) before forwarding the packet.

V-Flag: Value/Index Flag. If set, then the Prefix-SID carries an absolute value. If not set, then the Prefix-SID carries an index.

L-Flag: Local/Global Flag. If set, then the value/index carried by the Prefix-SID has local significance. If not set, then the value/index carried by this Sub-TLV has global significance.

Other bits: Reserved. These MUST be zero when sent and are ignored when received.

Reserved: SHOULD be set to 0 on transmission and MUST be ignored on reception.

Algorithm: Single octet identifying the algorithm the Prefix-SID is associated with as defined in [I-D.ietf-ospf-segment-routing-extensions].

A router receiving a Prefix-SID from a remote node and with an algorithm value that such remote node has not advertised in the SR-Algorithm Sub-TLV [I-D.ietf-ospf-segment-routing-extensions] MUST ignore the Prefix-SID Sub-TLV.

SID/Index/Label: According to the V-Flag and L-Flag, it contains:

V-flag is set to 0 and L-flag is set to 0: The SID/Index/Label field is a 4 octet index defining the offset in the SID/Label space advertised by this router

V-flag is set to 1 and L-flag is set to 1: The SID/Index/Label field is a 3 octet local label where the 20 rightmost bits are used for encoding the label value.

All other combinations of V-flag and L-flag are invalid and any SID advertisement received with an invalid setting for V and L flags MUST be ignored.

If an OSPFv3 router advertises multiple Prefix-SIDs for the same prefix, topology, and algorithm, all of them MUST be ignored.

When calculating the outgoing label for the prefix, the router MUST take into account, as described below, the E, NP, and M flags advertised by the next-hop router if that router advertised the SID for the prefix. This MUST be done regardless of whether the next-hop router contributes to the best path to the prefix.

The NP-Flag (No-PHP) MUST be set and the E-flag MUST be clear for Prefix-SIDs allocated to prefixes that are propagated between areas by an ABR based on intra-area or inter-area reachability, unless the advertised prefix is directly attached to such ABR.

The NP-Flag (No-PHP) MUST be set and the E-flag MUST be clear for Prefix-SIDs allocated to redistributed prefixes, unless the redistributed prefix is directly attached to the advertising ASBR.

If the NP-Flag is not set, then any upstream neighbor of the Prefix-SID originator MUST pop the Prefix-SID. This is equivalent to the penultimate hop popping mechanism used in the MPLS dataplane. If the NP-flag is not set, then the received E-flag is ignored.

If the NP-flag is set then:

If the E-flag is not set, then any upstream neighbor of the Prefix-SID originator MUST keep the Prefix-SID on top of the stack. This is useful when the originator of the Prefix-SID needs to stitch the incoming packet into a continuing MPLS LSP to the final destination. This could occur at an ABR (prefix propagation from one area to another) or at an ASBR (prefix propagation from one domain to another).

If the E-flag is set, then any upstream neighbor of the Prefix-SID originator MUST replace the Prefix-SID with an Explicit-NULL label. This is useful, e.g., when the originator of the Prefix-SID is the final destination for the related prefix and the originator wishes to receive the packet with the original Traffic Class field [RFC5462].

When the M-Flag is set, the NP-flag and the E-flag MUST be ignored on reception.

As the Mapping Server does not specify the originator of a prefix advertisement, it is not possible to determine PHP behavior solely based on the Mapping Server advertisement. However, PHP behavior SHOULD be done in following cases:

The Prefix is intra-area type and the downstream neighbor is the originator of the prefix.

The Prefix is inter-area type and the downstream neighbor is an ABR, which is advertising prefix reachability and is setting the LA-bit in the Prefix Options as described in [RFC8362].

The Prefix is external type and the downstream neighbor is an ASBR, which is advertising prefix reachability and is setting the LA-bit in the Prefix Options as described in [RFC8362].

When a Prefix-SID is advertised in the OSPFv3 Extended Prefix Range TLV, then the value advertised in the Prefix SID Sub-TLV is interpreted as a starting SID/Label value.

Example 1: If the following router addresses (loopback addresses) need to be mapped into the corresponding Prefix SID indexes:

```
Router-A: 2001:DB8::1/128, Prefix-SID: Index 1
Router-B: 2001:DB8::2/128, Prefix-SID: Index 2
Router-C: 2001:DB8::3/128, Prefix-SID: Index 3
Router-D: 2001:DB8::4/128, Prefix-SID: Index 4
```

then the Address Prefix field in the OSPFv3 Extended Prefix Range TLV would be set to 2001:DB8::1, the Prefix Length would be set to 128, the Range Size would be set to 4, and the Index value in the Prefix-SID Sub-TLV would be set to 1.

Example 2: If the following prefixes need to be mapped into the corresponding Prefix-SID indexes:

- 2001:DB8:1::0/120, Prefix-SID: Index 51
- 2001:DB8:1::100/120, Prefix-SID: Index 52
- 2001:DB8:1::200/120, Prefix-SID: Index 53
- 2001:DB8:1::300/120, Prefix-SID: Index 54
- 2001:DB8:1::400/120, Prefix-SID: Index 55
- 2001:DB8:1::500/120, Prefix-SID: Index 56
- 2001:DB8:1::600/120, Prefix-SID: Index 57

then the Prefix field in the OSPFv3 Extended Prefix Range TLV would be set to 2001:DB8:1::0, the Prefix Length would be set to 120, the Range Size would be set to 7, and the Index value in the Prefix-SID Sub-TLV would be set to 51.

7. Adjacency Segment Identifier (Adj-SID)

An Adjacency Segment Identifier (Adj-SID) represents a router adjacency in Segment Routing.

7.1. Adj-SID Sub-TLV

The Adj-SID Sub-TLV is an optional Sub-TLV of the Router-Link TLV as defined in [RFC8362]. It MAY appear multiple times in the Router-Link TLV. The Adj-SID Sub-TLV has the following format:

where:

Type: 5

Length: 7 or 8 octets, dependent on the V flag.

Flags: Single octet field containing the following flags:

```

0 1 2 3 4 5 6 7
+---+---+---+---+
|B|V|L|G|P|   |
+---+---+---+---+

```

where:

B-Flag: Backup Flag. If set, the Adj-SID refers to an adjacency that is eligible for protection (e.g., using IPFRR or MPLS-FRR) as described in section 3.5 of [RFC8402].

The V-Flag: Value/Index Flag. If set, then the Adj-SID carries an absolute value. If not set, then the Adj-SID carries an index.

The L-Flag: Local/Global Flag. If set, then the value/index carried by the Adj-SID has local significance. If not set, then the value/index carried by this Sub-TLV has global significance.

The G-Flag: Group Flag. When set, the G-Flag indicates that the Adj-SID refers to a group of adjacencies (and therefore MAY be assigned to other adjacencies as well).

P-Flag. Persistent flag. When set, the P-Flag indicates that the Adj-SID is persistently allocated, i.e., the Adj-SID value remains the same across router restart and/or interface flap.

Other bits: Reserved. These MUST be zero when sent and are ignored when received.

Reserved: SHOULD be set to 0 on transmission and MUST be ignored on reception.

Weight: Weight used for load-balancing purposes. The use of the weight is defined in [RFC8402].

SID/Index/Label: as described in Section 6.

An SR-capable router MAY allocate an Adj-SID for each of its adjacencies and set the B-Flag when the adjacency is eligible for protection by an FRR mechanism (IP or MPLS) as described in [RFC8402].

An SR-capable router MAY allocate more than one Adj-SID to an adjacency.

An SR-capable router MAY allocate the same Adj-SID to different adjacencies.

When the P-flag is not set, the Adj-SID MAY be persistent. When the P-flag is set, the Adj-SID MUST be persistent.

7.2. LAN Adj-SID Sub-TLV

The LAN Adj-SID Sub-TLV is an optional Sub-TLV of the Router-Link TLV. It MAY appear multiple times in the Router-Link TLV. It is used to advertise a SID/Label for an adjacency to a non-DR router on a broadcast, NBMA, or hybrid [RFC6845] network.

where:

Type: 6

Length: 11 or 12 octets, dependent on V-flag.

Flags: same as in Section 7.1

Weight: Weight used for load-balancing purposes. The use of the weight is defined in [RFC8402].

Reserved: SHOULD be set to 0 on transmission and MUST be ignored on reception.

Neighbor ID: The Router ID of the neighbor for which the LAN-Adj-SID is advertised.

SID/Index/Label: as described in Section 6.

When the P-flag is not set, the LAN Adj-SID MAY be persistent. When the P-flag is set, the LAN Adj-SID MUST be persistent.

8. Elements of Procedure

8.1. Intra-area Segment routing in OSPFv3

An OSPFv3 router that supports segment routing MAY advertise Prefix-SIDs for any prefix to which it is advertising reachability (e.g., a loopback IP address as described in Section 6).

A Prefix-SID can also be advertised by SR Mapping Servers (as described in [I-D.ietf-spring-segment-routing-ldp-interop]). A Mapping Server advertises Prefix-SIDs for remote prefixes that exist in the OSPFv3 routing domain. Multiple Mapping Servers can advertise Prefix-SIDs for the same prefix, in which case the same Prefix-SID MUST be advertised by all of them. The SR Mapping Server could use either area flooding scope or autonomous system flooding scope when advertising Prefix SIDs for prefixes, based on the configuration of the SR Mapping Server. Depending on the flooding scope used, the SR Mapping Server chooses the OSPFv3 LSA type that will be used. If the area flooding scope is needed, an E-Intra-Area-Prefix-LSA [RFC8362] is used. If autonomous system flooding scope is needed, an E-AS-External-LSA [RFC8362] is used.

When a Prefix-SID is advertised by the Mapping Server, which is indicated by the M-flag in the Prefix-SID Sub-TLV (Section 6), the route type as implied by the LSA type is ignored and the Prefix-SID is bound to the corresponding prefix independent of the route type.

Advertisement of the Prefix-SID by the Mapping Server using an Inter-Area Prefix TLV, External-Prefix TLV, or Intra-Area-Prefix TLV [RFC8362] does not itself contribute to the prefix reachability. The NU-bit [RFC5340] MUST be set in the PrefixOptions field of the LSA which is used by the Mapping Server to advertise SID or SID Range, which prevents the advertisement from contributing to prefix reachability.

An SR Mapping Server MUST use the OSPFv3 Extended Prefix Range TLVs when advertising SIDs for prefixes. Prefixes of different route-types can be combined in a single OSPFv3 Extended Prefix Range TLV advertised by an SR Mapping Server.

Area-scoped OSPFv3 Extended Prefix Range TLVs are propagated between areas, similar to propagation of prefixes between areas. Same rules that are used for propagating prefixes between areas [RFC5340] are used for the propagation of the prefix ranges.

8.2. Inter-area Segment routing in OSPFv3

In order to support SR in a multi-area environment, OSPFv3 MUST propagate Prefix-SID information between areas. The following procedure is used to propagate Prefix SIDs between areas.

When an OSPFv3 ABR advertises an Inter-Area-Prefix-LSA from an intra-area prefix to all its connected areas, it will also include the Prefix-SID Sub-TLV, as described in Section 6. The Prefix-SID value will be set as follows:

The ABR will look at its best path to the prefix in the source area and find the advertising router associated with the best path to that prefix.

The ABR will then determine if such router advertised a Prefix-SID for the prefix and use it when advertising the Prefix-SID to other connected areas.

If no Prefix-SID was advertised for the prefix in the source area by the router that contributes to the best path to the prefix, the originating ABR will use the Prefix-SID advertised by any other router when propagating the Prefix-SID for the prefix to other areas.

When an OSPFv3 ABR advertises Inter-Area-Prefix-LSA LSAs from an inter-area route to all its connected areas, it will also include the Prefix-SID Sub-TLV, as described in Section 6. The Prefix-SID value will be set as follows:

The ABR will look at its best path to the prefix in the backbone area and find the advertising router associated with the best path to that prefix.

The ABR will then determine if such router advertised a Prefix-SID for the prefix and use it when advertising the Prefix-SID to other connected areas.

If no Prefix-SID was advertised for the prefix in the backbone area by the ABR that contributes to the best path to the prefix, the originating ABR will use the Prefix-SID advertised by any other router when propagating the Prefix-SID for the prefix to other areas.

8.3. Segment Routing for External Prefixes

AS-External-LSAs are flooded domain wide. When an ASBR, which supports SR, originates an E-AS-External-LSA, it SHOULD also include a Prefix-SID Sub-TLV, as described in Section 6. The Prefix-SID value will be set to the SID that has been reserved for that prefix.

When an NSSA [RFC3101] ABR translates an E-NSSA-LSA into an E-AS-External-LSA, it SHOULD also advertise the Prefix-SID for the prefix. The NSSA ABR determines its best path to the prefix advertised in the translated E-NSSA-LSA and finds the advertising router associated with that path. If the advertising router has advertised a Prefix-SID for the prefix, then the NSSA ABR uses it when advertising the Prefix-SID for the E-AS-External-LSA. Otherwise, the Prefix-SID advertised by any other router will be used.

8.4. Advertisement of Adj-SID

The Adjacency Segment Routing Identifier (Adj-SID) is advertised using the Adj-SID Sub-TLV as described in Section 7.

8.4.1. Advertisement of Adj-SID on Point-to-Point Links

An Adj-SID MAY be advertised for any adjacency on a P2P link that is in neighbor state 2-Way or higher. If the adjacency on a P2P link transitions from the FULL state, then the Adj-SID for that adjacency MAY be removed from the area. If the adjacency transitions to a state lower than 2-Way, then the Adj-SID advertisement MUST be withdrawn from the area.

8.4.2. Adjacency SID on Broadcast or NBMA Interfaces

Broadcast, NBMA, or hybrid [RFC6845] networks in OSPFv3 are represented by a star topology where the DR is the central point to which all other routers on the broadcast, NBMA, or hybrid network connect. As a result, routers on the broadcast, NBMA, or hybrid network advertise only their adjacency to the DR. Routers that do not act as DR do not form or advertise adjacencies with each other. They do, however, maintain 2-Way adjacency state with each other and are directly reachable.

When Segment Routing is used, each router on the broadcast, NBMA, or hybrid network MAY advertise the Adj-SID for its adjacency to the DR using the Adj-SID Sub-TLV as described in Section 7.1.

SR-capable routers MAY also advertise a LAN-Adj-SID for other neighbors (e.g., BDR, DR-OTHER) on the broadcast, NBMA, or hybrid network using the LAN-Adj-SID Sub-TLV as described in Section 7.2.

9. IANA Considerations

This specification updates several existing OSPFv3 registries.

9.1. OSPFv3 Extended-LSA TLV Registry

Following values are allocated:

- o 9 - OSPFv3 Extended Prefix Range TLV

9.2. OSPFv3 Extended-LSA Sub-TLV registry

- o 4 - Prefix SID Sub-TLV
- o 5 - Adj-SID Sub-TLV
- o 6 - LAN Adj-SID Sub-TLV
- o 7 - SID/Label Sub-TLV

10. Security Considerations

With the OSPFv3 segment routing extensions defined herein, OSPFv3 will now program the MPLS data plane [RFC3031]. Previously, LDP [RFC5036] or another label distribution mechanism was required to advertise MPLS labels and program the MPLS data plane.

In general, the same types of attacks that can be carried out on the IP control plane can be carried out on the MPLS control plane resulting in traffic being misrouted in the respective data planes. However, the latter can be more difficult to detect and isolate.

Existing security extensions as described in [RFC5340] and [RFC8362] apply to these segment routing extensions. While OSPFv3 is under a single administrative domain, there can be deployments where potential attackers have access to one or more networks in the OSPFv3 routing domain. In these deployments, stronger authentication mechanisms such as those specified in [RFC4552] or [RFC7166] SHOULD be used.

Implementations MUST assure that malformed TLV and Sub-TLV defined in this document are detected and do not provide a vulnerability for attackers to crash the OSPFv3 router or routing process. Reception of a malformed TLV or Sub-TLV SHOULD be counted and/or logged for further analysis. Logging of malformed TLVs and Sub-TLVs SHOULD be rate-limited to prevent a Denial of Service (DoS) attack (distributed or otherwise) from overloading the OSPFv3 control plane.

OSPF Extensions for Segment Routing
draft-ietf-ospf-segment-routing-extensions-27

Abstract

Segment Routing (SR) allows a flexible definition of end-to-end paths within IGP topologies by encoding paths as sequences of topological sub-paths, called "segments". These segments are advertised by the link-state routing protocols (IS-IS and OSPF).

This draft describes the OSPFv2 extensions required for Segment Routing.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on June 6, 2019.

1. Introduction

Segment Routing (SR) allows a flexible definition of end-to-end paths within IGP topologies by encoding paths as sequences of topological sub-paths, called "segments". These segments are advertised by the link-state routing protocols (IS-IS and OSPF). Prefix segments represent an ECMP-aware shortest-path to a prefix (or a node), as per the state of the IGP topology. Adjacency segments represent a hop over a specific adjacency between two nodes in the IGP. A prefix segment is typically a multi-hop path while an adjacency segment, in most cases, is a one-hop path. SR's control-plane can be applied to both IPv6 and MPLS data-planes, and does not require any additional signalling (other than IGP extensions). The IPv6 data plane is out of the scope of this specification - it is not applicable to OSPFv2 which only supports the IPv4 address-family. When used in MPLS networks, SR paths do not require any LDP or RSVP-TE signalling. However, SR can interoperate in the presence of LSPs established with RSVP or LDP.

There are additional segment types, e.g., Binding SID defined in [I-D.ietf-spring-segment-routing].

This draft describes the OSPF extensions required for Segment Routing.

Segment Routing architecture is described in [I-D.ietf-spring-segment-routing].

Segment Routing use cases are described in [RFC7855].

2. Segment Routing Identifiers

Segment Routing defines various types of Segment Identifiers (SIDs): Prefix-SID, Adjacency-SID, LAN Adjacency SID, and Binding SID.

Extended Prefix/Link Opaque LSAs defined in [RFC7684] are used for advertisements of the various SID types.

2.1. SID/Label Sub-TLV

The SID/Label Sub-TLV appears in multiple TLVs or Sub-TLVs defined later in this document. It is used to advertise the SID or label associated with a prefix or adjacency. The SID/Label Sub-TLV has following format:

where:

Type: 1

Length: Variable, 3 or 4 octet

SID/Label: If length is set to 3, then the 20 rightmost bits represent a label. If length is set to 4, then the value represents a 32-bit SID.

The receiving router MUST ignore the SID/Label Sub-TLV if the length is other than 3 or 4.

3. Segment Routing Capabilities

Segment Routing requires some additional router capabilities to be advertised to other routers in the area.

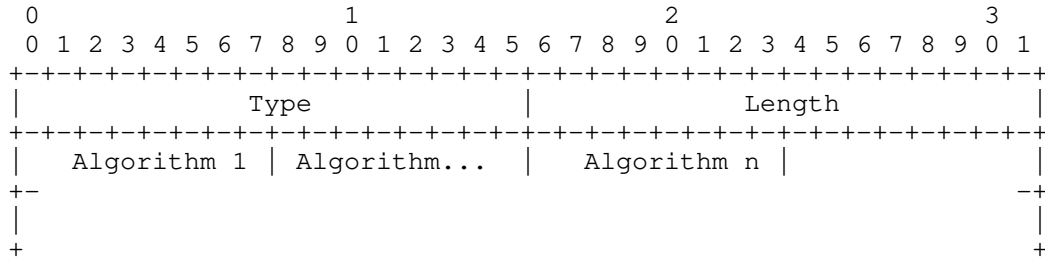

These SR capabilities are advertised in the Router Information Opaque LSA (defined in [RFC7770]). The TLVs defined below are applicable to both OSPFv2 and OSPFv3; see also [I-D.ietf-ospf-ospfv3-segment-routing-extensions]

3.1. SR-Algorithm TLV

The SR-Algorithm TLV is a top-level TLV of the Router Information Opaque LSA (defined in [RFC7770]).

The SR-Algorithm TLV is optional. It SHOULD only be advertised once in the Router Information Opaque LSA. If the SR-Algorithm TLV is not advertised by the node, such node is considered as not being segment routing capable.

An SR Router can use various algorithms when calculating reachability to OSPF routers or prefixes in an OSPF area. Examples of these algorithms are metric based Shortest Path First (SPF), various flavors of Constrained SPF, etc. The SR-Algorithm TLV allows a router to advertise the algorithms currently used by the router to other routers in an OSPF area. The SR-Algorithm TLV has following format:

where:

Type: 8

Variable, in octets, dependent on number of algorithms advertised.

Algorithm: Single octet identifying the algorithm. The following values are defined by this document:

0: Shortest Path First (SPF) algorithm based on link metric. This is the standard shortest path algorithm as computed by the OSPF protocol. Consistent with the deployed practice for link-state protocols, Algorithm 0 permits any node to overwrite the SPF path with a different path based on its local policy. If the SR-Algorithm TLV is advertised, Algorithm 0 MUST be included.

1: Strict Shortest Path First (SPF) algorithm based on link metric. The algorithm is identical to Algorithm 0 but Algorithm 1 requires that all nodes along the path will honor the SPF routing decision. Local policy at the node claiming support for Algorithm 1 MUST NOT alter the SPF paths computed by Algorithm 1.

When multiple SR-Algorithm TLVs are received from a given router, the receiver MUST use the first occurrence of the TLV in the Router Information LSA. If the SR-Algorithm TLV appears in multiple Router Information LSAs that have different flooding scopes, the SR-Algorithm TLV in the Router Information LSA with the area-scoped flooding scope MUST be used. If the SR-Algorithm TLV appears in

multiple Router Information LSAs that have the same flooding scope, the SR-Algorithm TLV in the Router Information (RI) LSA with the numerically smallest Instance ID MUST be used and subsequent instances of the SR-Algorithm TLV MUST be ignored.

The RI LSA can be advertised at any of the defined opaque flooding scopes (link, area, or Autonomous System (AS)). For the purpose of SR-Algorithm TLV advertisement, area-scoped flooding is REQUIRED.

3.2. SID/Label Range TLV

Prefix SIDs MAY be advertised in a form of an index as described in Section 5. Such index defines the offset in the SID/Label space advertised by the router. The SID/Label Range TLV is used to advertise such SID/Label space.

The SID/Label Range TLV is a top-level TLV of the Router Information Opaque LSA (defined in [RFC7770]).

The SID/Label Range TLV MAY appear multiple times and has the following format:

where:

Type: 9

Length: Variable, in octets, dependent on Sub-TLVs.

Range Size: 3-octet SID/label range size (i.e., the number of SIDs or labels in the range including the first SID/label). It MUST be greater than 0.

Reserved: SHOULD be set to 0 on transmission and MUST be ignored on reception.

Initially, the only supported Sub-TLV is the SID/Label Sub-TLV as defined in Section 2.1. The SID/Label Sub-TLV MUST be included in the SID/Label Range TLV. The SID/Label advertised in the SID/Label Sub-TLV represents the first SID/Label in the advertised range.

Only a single SID/Label Sub-TLV MAY be advertised in SID/Label Range TLV. If more than one SID/Label Sub-TLVs are present, the SID/Label Range TLV MUST be ignored.

Multiple occurrences of the SID/Label Range TLV MAY be advertised, in order to advertise multiple ranges. In such case:

- o The originating router MUST encode each range into a different SID/Label Range TLV.
- o The originating router decides the order in which the set of SID/Label Range TLVs are advertised inside the Router Information Opaque LSA. The originating router MUST ensure the order is the same after a graceful restart (using checkpointing, non-volatile storage, or any other mechanism) in order to assure the SID/label range and SID index correspondence is preserved across graceful restarts.
- o The receiving router MUST adhere to the order in which the ranges are advertised when calculating a SID/label from a SID index.
- o The originating router MUST NOT advertise overlapping ranges.
- o When a router receives multiple overlapping ranges, it MUST conform to the procedures defined in [I-D.ietf-spring-segment-routing-mps].

The following example illustrates the advertisement of multiple ranges:

The originating router advertises the following ranges:

```
Range 1: Range Size: 100   SID/Label Sub-TLV: 100
Range 1: Range Size: 100   SID/Label Sub-TLV: 1000
Range 1: Range Size: 100   SID/Label Sub-TLV: 500
```

The receiving routers concatenate the ranges and build the Segment Routing Global Block (SRGB) as follows:

```
SRGB = [100, 199]
        [1000, 1099]
        [500, 599]
```

The indexes span multiple ranges:

```
index=0 means label 100
...
index 99 means label 199
index 100 means label 1000
index 199 means label 1099
...
index 200 means label 500
...
```

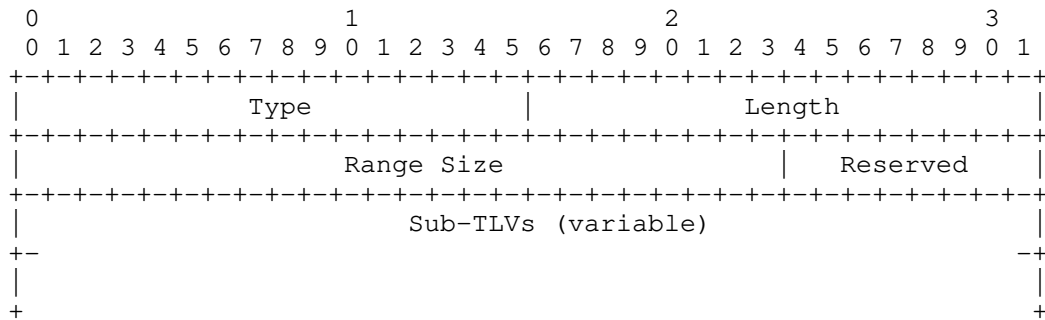

The RI LSA can be advertised at any of the defined flooding scopes (link, area, or autonomous system (AS)). For the purpose of SID/Label Range TLV advertisement, area-scoped flooding is REQUIRED.

3.3. SR Local Block TLV

The SR Local Block TLV (SRLB TLV) contains the range of labels the node has reserved for local SIDs. SIDs from the SRLB MAY be used for Adjacency-SIDs, but also by components other than the OSPF protocol. As an example, an application or a controller can instruct the router to allocate a specific local SID. Some controllers or applications can use the control plane to discover the available set of local SIDs on a particular router. In such cases, the SRLB is advertised in the control plane. The requirement to advertise the SRLB is further described in [I-D.ietf-spring-segment-routing-mpls]. The SRLB TLV is used to advertise the SRLB.

The SRLB TLV is a top-level TLV of the Router Information Opaque LSA (defined in [RFC7770]).

The SRLB TLV MAY appear multiple times in the Router Information Opaque LSA and has the following format:

where:

Type: 14

Length: Variable, in octets, dependent on Sub-TLVs.

Range Size: 3-octet SID/label range size (i.e., the number of SIDs or labels in the range including the first SID/label). It MUST be greater than 0.

Reserved: SHOULD be set to 0 on transmission and MUST be ignored on reception.

Initially, the only supported Sub-TLV is the SID/Label Sub-TLV as defined in Section 2.1. The SID/Label Sub-TLV MUST be included in the SRLB TLV. The SID/Label advertised in the SID/Label Sub-TLV represents the first SID/Label in the advertised range.

Only a single SID/Label Sub-TLV MAY be advertised in the SRLB TLV. If more than one SID/Label Sub-TLVs are present, the SRLB TLV MUST be ignored.

The originating router MUST NOT advertise overlapping ranges.

Each time a SID from the SRLB is allocated, it SHOULD also be reported to all components (e.g., controller or applications) in order for these components to have an up-to-date view of the current SRLB allocation. This is required to avoid collisions between allocation instructions.

Within the context of OSPF, the reporting of local SIDs is done through OSPF Sub-TLVs such as the Adjacency-SID (Section 6). However, the reporting of allocated local SIDs can also be done through other means and protocols which are outside the scope of this document.

A router advertising the SRLB TLV MAY also have other label ranges, outside of the SRLB, used for its local allocation purposes which are not advertised in the SRLB TLV. For example, it is possible that an Adjacency-SID is allocated using a local label that is not part of the SRLB.

The RI LSA can be advertised at any of the defined flooding scopes (link, area, or autonomous system (AS)). For the purpose of SRLB TLV advertisement, area-scoped flooding is REQUIRED.

3.4. SRMS Preference TLV

The Segment Routing Mapping Server Preference TLV (SRMS Preference TLV) is used to advertise a preference associated with the node that acts as an SR Mapping Server. The role of an SRMS is described in [I-D.ietf-spring-segment-routing-ldp-interop]. SRMS preference is defined in [I-D.ietf-spring-segment-routing-ldp-interop].

The SRMS Preference TLV is a top-level TLV of the Router Information Opaque LSA (defined in [RFC7770]).

The SRMS Preference TLV MAY only be advertised once in the Router Information Opaque LSA and has the following format:

where:

Type: 15

Length: 4 octets

Preference: 1 octet. SRMS preference value from 0 to 255.

Reserved: SHOULD be set to 0 on transmission and MUST be ignored on reception.

When multiple SRMS Preference TLVs are received from a given router, the receiver MUST use the first occurrence of the TLV in the Router Information LSA. If the SRMS Preference TLV appears in multiple Router Information LSAs that have different flooding scopes, the SRMS Preference TLV in the Router Information LSA with the narrowest

flooding scope MUST be used. If the SRMS Preference TLV appears in multiple Router Information LSAs that have the same flooding scope, the SRMS Preference TLV in the Router Information LSA with the numerically smallest Instance ID MUST be used and subsequent instances of the SRMS Preference TLV MUST be ignored.

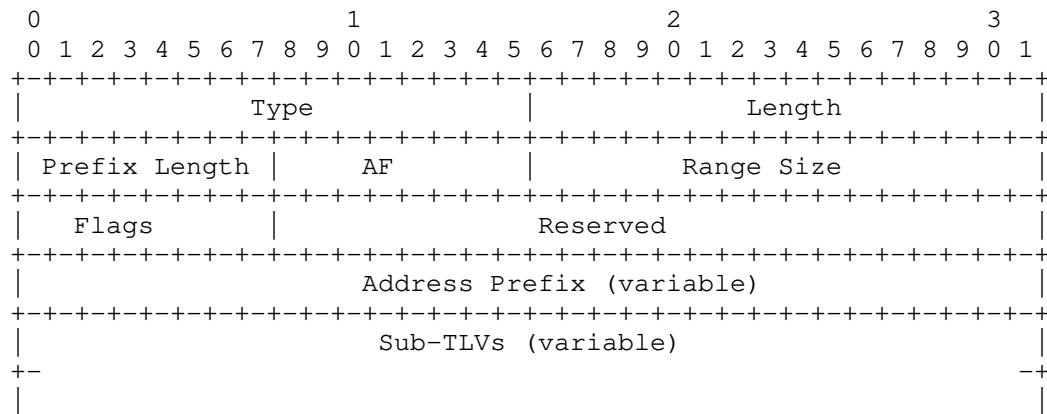

The RI LSA can be advertised at any of the defined flooding scopes (link, area, or autonomous system (AS)). For the purpose of the SRMS Preference TLV advertisement, AS-scoped flooding SHOULD be used. This is because SRMS servers can be located in a different area than consumers of the SRMS advertisements. If the SRMS advertisements from the SRMS server are only used inside the SRMS server's area, area-scoped flooding MAY be used.

4. OSPF Extended Prefix Range TLV

In some cases it is useful to advertise attributes for a range of prefixes. The Segment Routing Mapping Server, which is described in [I-D.ietf-spring-segment-routing-ldp-interop], is an example where we need a single advertisement to advertise SIDs for multiple prefixes from a contiguous address range.

The OSPF Extended Prefix Range TLV, which is a top level TLV of the Extended Prefix LSA described in [RFC7684] is defined for this purpose.

Multiple OSPF Extended Prefix Range TLVs MAY be advertised in each OSPF Extended Prefix Opaque LSA, but all prefix ranges included in a single OSPF Extended Prefix Opaque LSA MUST have the same flooding scope. The OSPF Extended Prefix Range TLV has the following format:

where:

Type: 2

Length: Variable, in octets, dependent on Sub-TLVs.

Prefix length: Length of prefix in bits.

AF: Address family for the prefix. Currently, the only supported value is 0 for IPv4 unicast. The inclusion of address family in this TLV allows for future extension.

Range size: Represents the number of prefixes that are covered by the advertisement. The Range Size MUST NOT exceed the number of prefixes that could be satisfied by the prefix length without including the IPv4 multicast address range (224.0.0.0/3).

Flags: Single octet field. The following flags are defined:

```

  0  1  2  3  4  5  6  7
+---+---+---+---+---+---+---+---+
| IA |   |   |   |   |   |   |   |
+---+---+---+---+---+---+---+---+

```

where:

IA-Flag: Inter-Area flag. If set, advertisement is of inter-area type. An ABR that is advertising the OSPF Extended Prefix Range TLV between areas MUST set this bit.

This bit is used to prevent redundant flooding of Prefix Range TLVs between areas as follows:

An ABR only propagates an inter-area Prefix Range advertisement from the backbone area to connected non-backbone areas if the advertisement is considered to be the best one. The following rules are used to select the best range from the set of advertisements for the same Prefix Range:

An ABR always prefers intra-area Prefix Range advertisements over inter-area advertisements.

An ABR does not consider inter-area Prefix Range advertisements coming from non-backbone areas.

Reserved: SHOULD be set to 0 on transmission and MUST be ignored on reception.

Address Prefix: For the address family IPv4 unicast, the prefix itself is encoded as a 32-bit value. The default route is represented by a prefix of length 0. Prefix encoding for other address families is beyond the scope of this specification.

5. Prefix SID Sub-TLV

The Prefix SID Sub-TLV is a Sub-TLV of the OSPF Extended Prefix TLV described in [RFC7684] and the OSPF Extended Prefix Range TLV described in Section 4. It MAY appear more than once in the parent TLV and has the following format:

where:

Type: 2

Length: 7 or 8 octets, dependent on the V-flag

Flags: Single octet field. The following flags are defined:

where:

NP-Flag: No-PHP flag. If set, then the penultimate hop MUST NOT pop the Prefix-SID before delivering packets to the node that advertised the Prefix-SID.

M-Flag: Mapping Server Flag. If set, the SID was advertised by a Segment Routing Mapping Server as described in [I-D.ietf-spring-segment-routing-ldp-interop].

E-Flag: Explicit-Null Flag. If set, any upstream neighbor of the Prefix-SID originator MUST replace the Prefix-SID with the Explicit-NULL label (0 for IPv4) before forwarding the packet.

V-Flag: Value/Index Flag. If set, then the Prefix-SID carries an absolute value. If not set, then the Prefix-SID carries an index.

L-Flag: Local/Global Flag. If set, then the value/index carried by the Prefix-SID has local significance. If not set, then the value/index carried by this Sub-TLV has global significance.

Other bits: Reserved. These MUST be zero when sent and are ignored when received.

Reserved: SHOULD be set to 0 on transmission and MUST be ignored on reception.

MT-ID: Multi-Topology ID (as defined in [RFC4915]).

Algorithm: Single octet identifying the algorithm the Prefix-SID is associated with as defined in Section 3.1.

A router receiving a Prefix-SID from a remote node and with an algorithm value that such remote node has not advertised in the SR-Algorithm Sub-TLV (Section 3.1) MUST ignore the Prefix-SID Sub-TLV.

SID/Index/Label: According to the V and L flags, it contains:

V-flag is set to 0 and L-flag is set to 0: The SID/Index/Label field is a 4 octet index defining the offset in the SID/Label space advertised by this router

V-flag is set to 1 and L-flag is set to 1: The SID/Index/Label field is a 3 octet local label where the 20 rightmost bits are used for encoding the label value.

All other combinations of V-flag and L-flag are invalid and any SID advertisement received with an invalid setting for V and L flags MUST be ignored.

If an OSPF router advertises multiple Prefix-SIDs for the same prefix, topology and algorithm, all of them MUST be ignored.

When calculating the outgoing label for the prefix, the router MUST take into account, as described below, the E, NP and M flags

advertised by the next-hop router if that router advertised the SID for the prefix. This MUST be done regardless of whether the next-hop router contributes to the best path to the prefix.

The NP-Flag (No-PHP) MUST be set and the E-flag MUST be clear for Prefix-SIDs allocated to inter-area prefixes that are originated by the ABR based on intra-area or inter-area reachability between areas, unless the advertised prefix is directly attached to the ABR.

The NP-Flag (No-PHP) MUST be set and the E-flag MUST be clear for Prefix-SIDs allocated to redistributed prefixes, unless the redistributed prefix is directly attached to the ASBR.

If the NP-Flag is not set, then any upstream neighbor of the Prefix-SID originator MUST pop the Prefix-SID. This is equivalent to the penultimate hop popping mechanism used in the MPLS dataplane. If the NP-flag is not set, then the received E-flag is ignored.

If the NP-flag is set then:

If the E-flag is not set, then any upstream neighbor of the Prefix-SID originator MUST keep the Prefix-SID on top of the stack. This is useful when the originator of the Prefix-SID need to stitch the incoming packet into a continuing MPLS LSP to the final destination. This could occur at an Area Border Router (prefix propagation from one area to another) or at an AS Boundary Router (prefix propagation from one domain to another).

If the E-flag is set, then any upstream neighbor of the Prefix-SID originator MUST replace the Prefix-SID with an Explicit-NULL label. This is useful, e.g., when the originator of the Prefix-SID is the final destination for the related prefix and the originator wishes to receive the packet with the original EXP bits.

When the M-Flag is set, the NP-flag and the E-flag MUST be ignored at reception.

As the Mapping Server does not specify the originator of a prefix advertisement, it is not possible to determine PHP behavior solely based on the Mapping Server advertisement. However, PHP behavior SHOULD be done in following cases:

The Prefix is intra-area type and the downstream neighbor is the originator of the prefix.

The Prefix is inter-area type and downstream neighbor is an ABR, which is advertising prefix reachability and is also generating

the Extended Prefix TLV with the A-flag set for this prefix as described in section 2.1 of [RFC7684].

The Prefix is external type and downstream neighbor is an ASBR, which is advertising prefix reachability and is also generating the Extended Prefix TLV with the A-flag set for this prefix as described in section 2.1 of [RFC7684].

When a Prefix-SID is advertised in an Extended Prefix Range TLV, then the value advertised in the Prefix SID Sub-TLV is interpreted as a starting SID/Label value.

Example 1: If the following router addresses (loopback addresses) need to be mapped into the corresponding Prefix SID indexes:

```
Router-A: 192.0.2.1/32, Prefix-SID: Index 1
Router-B: 192.0.2.2/32, Prefix-SID: Index 2
Router-C: 192.0.2.3/32, Prefix-SID: Index 3
Router-D: 192.0.2.4/32, Prefix-SID: Index 4
```

then the Prefix field in the Extended Prefix Range TLV would be set to 192.0.2.1, Prefix Length would be set to 32, Range Size would be set to 4, and the Index value in the Prefix-SID Sub-TLV would be set to 1.

Example 2: If the following prefixes need to be mapped into the corresponding Prefix-SID indexes:

```
192.0.2.0/30, Prefix-SID: Index 51
192.0.2.4/30, Prefix-SID: Index 52
192.0.2.8/30, Prefix-SID: Index 53
192.0.2.12/30, Prefix-SID: Index 54
192.0.2.16/30, Prefix-SID: Index 55
192.0.2.20/30, Prefix-SID: Index 56
192.0.2.24/30, Prefix-SID: Index 57
```

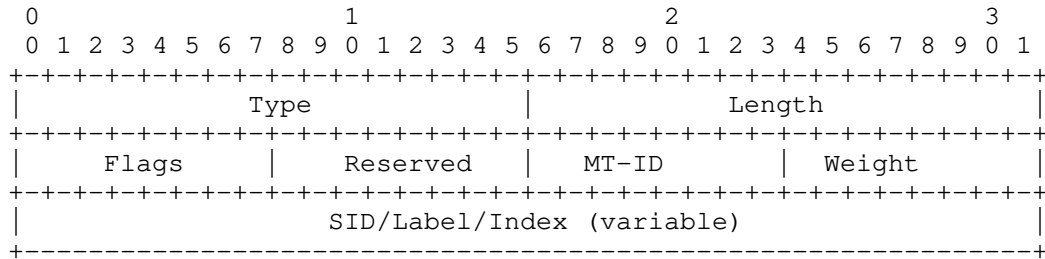

then the Prefix field in the Extended Prefix Range TLV would be set to 192.0.2.0, Prefix Length would be set to 30, Range Size would be 7, and the Index value in the Prefix-SID Sub-TLV would be set to 51.

6. Adjacency Segment Identifier (Adj-SID)

An Adjacency Segment Identifier (Adj-SID) represents a router adjacency in Segment Routing.

6.1. Adj-SID Sub-TLV

Adj-SID is an optional Sub-TLV of the Extended Link TLV defined in [RFC7684]. It MAY appear multiple times in the Extended Link TLV. The Adj-SID Sub-TLV has the following format:

where:

Type: 2

Length: 7 or 8 octets, dependent on the V flag.

Flags: Single octet field containing the following flags:

where:

B-Flag: Backup Flag. If set, the Adj-SID refers to an adjacency that is eligible for protection (e.g., using IPFRR or MPLS-FRR) as described in section 3.5 of [I-D.ietf-spring-segment-routing].

The V-Flag: Value/Index Flag. If set, then the Adj-SID carries an absolute value. If not set, then the Adj-SID carries an index.

The L-Flag: Local/Global Flag. If set, then the value/index carried by the Adj-SID has local significance. If not set, then the value/index carried by this Sub-TLV has global significance.

The G-Flag: Group Flag. When set, the G-Flag indicates that the Adj-SID refers to a group of adjacencies (and therefore MAY be assigned to other adjacencies as well).

P-Flag. Persistent flag. When set, the P-Flag indicates that the Adj-SID is persistently allocated, i.e., the Adj-SID value remains consistent across router restart and/or interface flap.

Other bits: Reserved. These MUST be zero when sent and are ignored when received.

Reserved: SHOULD be set to 0 on transmission and MUST be ignored on reception.

MT-ID: Multi-Topology ID (as defined in [RFC4915]).

Weight: Weight used for load-balancing purposes. The use of the weight is defined in [I-D.ietf-spring-segment-routing].

SID/Index/Label: as described in Section 5.

An SR capable router MAY allocate an Adj-SID for each of its adjacencies and set the B-Flag when the adjacency is eligible for protection by an FRR mechanism (IP or MPLS) as described in section 3.5 of [I-D.ietf-spring-segment-routing].

An SR capable router MAY allocate more than one Adj-SID to an adjacency

An SR capable router MAY allocate the same Adj-SID to different adjacencies

When the P-flag is not set, the Adj-SID MAY be persistent. When the P-flag is set, the Adj-SID MUST be persistent.

6.2. LAN Adj-SID Sub-TLV

LAN Adj-SID is an optional Sub-TLV of the Extended Link TLV defined in [RFC7684]. It MAY appear multiple times in the Extended-Link TLV. It is used to advertise a SID/Label for an adjacency to a non-DR router on a broadcast, NBMA, or hybrid [RFC6845] network.

where:

Type: 3

Length: 11 or 12 octets, dependent on V-flag.

Flags: same as in Section 6.1

Reserved: SHOULD be set to 0 on transmission and MUST be ignored on reception.

MT-ID: Multi-Topology ID (as defined in [RFC4915]).

Weight: Weight used for load-balancing purposes. The use of the weight is defined in [I-D.ietf-spring-segment-routing].

Neighbor ID: The Router ID of the neighbor for which the LAN-Adj-SID is advertised.

SID/Index/Label: as described in Section 5.

When the P-flag is not set, the Adj-SID MAY be persistent. When the P-flag is set, the Adj-SID MUST be persistent.

7. Elements of Procedure

7.1. Intra-area Segment routing in OSPFv2

An OSPFv2 router that supports segment routing MAY advertise Prefix-SIDs for any prefix to which it is advertising reachability (e.g., a loopback IP address as described in Section 5).

A Prefix-SID can also be advertised by the SR Mapping Servers (as described in [I-D.ietf-spring-segment-routing-ldp-interop]). A Mapping Server advertises Prefix-SIDs for remote prefixes that exist in the OSPFv2 routing domain. Multiple Mapping Servers can advertise

Prefix-SIDs for the same prefix, in which case the same Prefix-SID MUST be advertised by all of them. The flooding scope of the OSPF Extended Prefix Opaque LSA that is generated by the SR Mapping Server could be either area-scoped or AS-scoped and is determined based on the configuration of the SR Mapping Server.

An SR Mapping Server MUST use the OSPF Extended Prefix Range TLV when advertising SIDs for prefixes. Prefixes of different route-types can be combined in a single OSPF Extended Prefix Range TLV advertised by an SR Mapping Server. Because the OSPF Extended Prefix Range TLV doesn't include a Route-Type field, as in the OSPF Extended Prefix TLV, it is possible to include adjacent prefixes from different Route-Types in the OSPF Extended Prefix Range TLV.

Area-scoped OSPF Extended Prefix Range TLVs are propagated between areas. Similar to propagation of prefixes between areas, an ABR only propagates the OSPF Extended Prefix Range TLV that it considers to be the best from the set it received. The rules used to pick the best OSPF Extended Prefix Range TLV are described in Section 4.

When propagating an OSPF Extended Prefix Range TLV between areas, ABRs MUST set the IA-Flag, that is used to prevent redundant flooding of the OSPF Extended Prefix Range TLV between areas as described in Section 4.

7.2. Inter-area Segment routing in OSPFv2

In order to support SR in a multi-area environment, OSPFv2 MUST propagate Prefix-SID information between areas. The following procedure is used to propagate Prefix SIDs between areas.

When an OSPF ABR advertises a Type-3 Summary LSA from an intra-area prefix to all its connected areas, it will also originate an Extended Prefix Opaque LSA, as described in [RFC7684]. The flooding scope of the Extended Prefix Opaque LSA type will be set to area-local scope. The route-type in the OSPF Extended Prefix TLV is set to inter-area. The Prefix-SID Sub-TLV will be included in this LSA and the Prefix-SID value will be set as follows:

The ABR will look at its best path to the prefix in the source area and find the advertising router associated with the best path to that prefix.

The ABR will then determine if such router advertised a Prefix-SID for the prefix and use it when advertising the Prefix-SID to other connected areas.

If no Prefix-SID was advertised for the prefix in the source area by the router that contributes to the best path to the prefix, the originating ABR will use the Prefix-SID advertised by any other router when propagating the Prefix-SID for the prefix to other areas.

When an OSPF ABR advertises Type-3 Summary LSAs from an inter-area route to all its connected areas, it will also originate an Extended Prefix Opaque LSA, as described in [RFC7684]. The flooding scope of the Extended Prefix Opaque LSA type will be set to area-local scope. The route-type in OSPF Extended Prefix TLV is set to inter-area. The Prefix-SID Sub-TLV will be included in this LSA and the Prefix-SID will be set as follows:

The ABR will look at its best path to the prefix in the backbone area and find the advertising router associated with the best path to that prefix.

The ABR will then determine if such router advertised a Prefix-SID for the prefix and use it when advertising the Prefix-SID to other connected areas.

If no Prefix-SID was advertised for the prefix in the backbone area by the ABR that contributes to the best path to the prefix, the originating ABR will use the Prefix-SID advertised by any other router when propagating the Prefix-SID for the prefix to other areas.

7.3. Segment Routing for External Prefixes

Type-5 LSAs are flooded domain wide. When an ASBR, which supports SR, generates Type-5 LSAs, it SHOULD also originate Extended Prefix Opaque LSAs, as described in [RFC7684]. The flooding scope of the Extended Prefix Opaque LSA type is set to AS-wide scope. The route-type in the OSPF Extended Prefix TLV is set to external. The Prefix-SID Sub-TLV is included in this LSA and the Prefix-SID value will be set to the SID that has been reserved for that prefix.

When an NSSA [RFC3101] ABR translates Type-7 LSAs into Type-5 LSAs, it SHOULD also advertise the Prefix-SID for the prefix. The NSSA ABR determines its best path to the prefix advertised in the translated Type-7 LSA and finds the advertising router associated with that path. If the advertising router has advertised a Prefix-SID for the prefix, then the NSSA ABR uses it when advertising the Prefix-SID for the Type-5 prefix. Otherwise, the Prefix-SID advertised by any other router will be used.

7.4. Advertisement of Adj-SID

The Adjacency Segment Routing Identifier (Adj-SID) is advertised using the Adj-SID Sub-TLV as described in Section 6.

7.4.1. Advertisement of Adj-SID on Point-to-Point Links

An Adj-SID MAY be advertised for any adjacency on a P2P link that is in neighbor state 2-Way or higher. If the adjacency on a P2P link transitions from the FULL state, then the Adj-SID for that adjacency MAY be removed from the area. If the adjacency transitions to a state lower than 2-Way, then the Adj-SID advertisement MUST be withdrawn from the area.

7.4.2. Adjacency SID on Broadcast or NBMA Interfaces

Broadcast, NBMA, or hybrid [RFC6845] networks in OSPF are represented by a star topology where the Designated Router (DR) is the central point to which all other routers on the broadcast, NBMA, or hybrid network connect. As a result, routers on the broadcast, NBMA, or hybrid network advertise only their adjacency to the DR. Routers that do not act as DR do not form or advertise adjacencies with each other. They do, however, maintain 2-Way adjacency state with each other and are directly reachable.

When Segment Routing is used, each router on the broadcast, NBMA, or hybrid network MAY advertise the Adj-SID for its adjacency to the DR using the Adj-SID Sub-TLV as described in Section 6.1.

SR capable routers MAY also advertise a LAN-Adj-SID for other neighbors (e.g., BDR, DR-OTHER) on the broadcast, NBMA, or hybrid network using the LAN-ADJ-SID Sub-TLV as described in Section 6.2.

8. IANA Considerations

This specification updates several existing OSPF registries.

8.1. OSPF Router Information (RI) TLVs Registry

- o 8 (IANA Preallocated) - SR-Algorithm TLV
- o 9 (IANA Preallocated) - SID/Label Range TLV
- o 14 - SR Local Block TLV
- o 15 - SRMS Preference TLV

8.2. OSPFv2 Extended Prefix Opaque LSA TLVs Registry

Following values are allocated:

- o 2 - OSPF Extended Prefix Range TLV

8.3. OSPFv2 Extended Prefix TLV Sub-TLVs Registry

Following values are allocated:

- o 1 - SID/Label Sub-TLV
- o 2 - Prefix SID Sub-TLV

8.4. OSPFv2 Extended Link TLV Sub-TLVs Registry

Following initial values are allocated:

- o 1 - SID/Label Sub-TLV
- o 2 - Adj-SID Sub-TLV
- o 3 - LAN Adj-SID/Label Sub-TLV

8.5. IGP Algorithm Type Registry

IANA is requested to set up a registry called "IGP Algorithm Type" under a new category of "Interior Gateway Protocol (IGP) Parameters" IANA registries. The registration policy for this registry is "Standards Action" ([RFC8126] and [RFC7120]).

Values in this registry come from the range 0-255.

The initial values in the IGP Algorithm Type registry are:

0: Shortest Path First (SPF) algorithm based on link metric. This is the standard shortest path algorithm as computed by the IGP protocol. Consistent with the deployed practice for link-state protocols, Algorithm 0 permits any node to overwrite the SPF path with a different path based on its local policy.

1: Strict Shortest Path First (SPF) algorithm based on link metric. The algorithm is identical to Algorithm 0 but Algorithm 1 requires that all nodes along the path will honor the SPF routing decision. Local policy at the node claiming support for Algorithm 1 MUST NOT alter the SPF paths computed by Algorithm 1.

9. Implementation Status

An implementation survey with seven questions related to the implementer's support of OSPFv2 Segment Routing was sent to the OSPF WG list and several known implementers. This section contains responses from three implementers who completed the survey. No external means were used to verify the accuracy of the information submitted by the respondents. The respondents are considered experts on the products they reported on. Additionally, responses were omitted from implementers who indicated that they have not implemented the function yet.

This section will be removed before publication as an RFC.

Responses from Nokia (former Alcatel-Lucent):

Link to a web page describing the implementation:

https://infoproducts.alcatel-lucent.com/cgi-bin/dbaccessfilename.cgi/3HE10799AAAATQZZA01_V1_7450%20ESS%207750%20SR%20and%207950%20XRS%20Unicast%20Routing%20Protocols%20Guide%20R14.0.R1.pdf

The implementation's level of maturity: Production.

Coverage: We have implemented all sections and have support for the latest draft.

Licensing: Part of the software package that needs to be purchased.

Implementation experience: Great spec. We also performed interoperability testing with Cisco's OSPF Segment Routing implementation.

Contact information: wim.henderickx@nokia.com

Responses from Cisco Systems:

Link to a web page describing the implementation:

<http://www.segment-routing.net/home/tutorial>

The implementation's level of maturity: Production.

Coverage: All sections have been implemented according to the latest draft.

Licensing: Part of a commercial software package.

Implementation experience: Many aspects of the draft are result of the actual implementation experience, as the draft evolved from its

initial version to the current one. Interoperability testing with Alcatel-Lucent was performed, which confirmed the draft's ability to serve as a reference for the implementors.

Contact information: ppsenak@cisco.com

Responses from Juniper:

The implementation's name and/or a link to a web page describing the implementation:

Feature name is OSPF SPRING

The implementation's level of maturity: To be released in 16.2 (second half of 2016)

Coverage: All sections implemented except Sections 4, and 6.

Licensing: JUNOS Licensing needed.

Implementation experience: NA

Contact information: shraddha@juniper.net

10. Security Considerations

With the OSPFv2 segment routing extensions defined herein, OSPFv2 will now program the MPLS data plane [RFC3031] in addition to the IP data plane. Previously, LDP [RFC5036] or another label distribution mechanism was required to advertise MPLS labels and program the MPLS data plane.

In general, the same types of attacks that can be carried out on the IP control plane can be carried out on the MPLS control plane resulting in traffic being misrouted in the respective data planes. However, the latter can be more difficult to detect and isolate.

Existing security extensions as described in [RFC2328] and [RFC7684] apply to these segment routing extensions. While OSPF is under a single administrative domain, there can be deployments where potential attackers have access to one or more networks in the OSPF routing domain. In these deployments, stronger authentication mechanisms such as those specified in [RFC7474] SHOULD be used.

Implementations MUST assure that malformed TLV and Sub-TLV defined in this document are detected and do not provide a vulnerability for attackers to crash the OSPFv2 router or routing process. Reception of malformed TLV or Sub-TLV SHOULD be counted and/or logged for

further analysis. Logging of malformed TLVs and Sub-TLVs SHOULD be rate-limited to prevent a Denial of Service (DoS) attack (distributed or otherwise) from overloading the OSPF control plane.

11. Contributors

The following people gave a substantial contribution to the content of this document: Acee Lindem, Ahmed Bashandy, Martin Horneffer, Bruno Decraene, Stephane Litkowski, Igor Milojevic, Rob Shakir and Saku Ytti.

YANG Data Model for OSPF Protocol
draft-ietf-ospf-yang-28

Abstract

This document defines a YANG data model that can be used to configure and manage OSPF. The model is based on YANG1.1 as defined in RFC 7950 and conforms to the Network Management Datastore Architecture (NMDA) as described in RFC 8342.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on February 27, 2020.

1. Overview

YANG [RFC6020][RFC7950] is a data definition language used to define the contents of a conceptual data store that allows networked devices to be managed using NETCONF [RFC6241], RESTCONF [RFC8040], and other Network Management protocols. Furthermore, YANG data models can be used as the basis for implementation of other interfaces, such as CLI and programmatic APIs.

This document defines a YANG data model that can be used to configure and manage OSPF and it is an augmentation to the core routing data model. It fully conforms to the Network Management Datastore Architecture (NMDA) [RFC8342]. A core routing data model is defined in [RFC8349], and it provides the basis for the development of data models for routing protocols. The interface data model is defined in [RFC8343] and is used for referencing interfaces from the routing

protocol. The key-chain data model used for OSPF authentication is defined in [RFC8177] and provides both a reference to configured key-chains and an enumeration of cryptographic algorithms.

Both OSPFv2 [RFC2328] and OSPFv3 [RFC5340] are supported. In addition to the core OSPF protocol, features described in other OSPF RFCs are also supported. These includes demand circuit [RFC1793], traffic engineering [RFC3630], multiple address family [RFC5838], graceful restart [RFC3623] [RFC5187], NSSA [RFC3101], and OSPFv2 or OSPFv3 as a PE-CE Protocol [RFC4577], [RFC6565]. These non-core features are optional in the OSPF data model.

1.1. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

1.2. Tree Diagrams

This document uses the graphical representation of data models defined in [RFC8340].

2. Design of Data Model

Although the basis of OSPF configuration elements like routers, areas, and interfaces remains the same, the detailed configuration model varies among router vendors. Differences are observed in terms of how the protocol instance is tied to the routing domain and how multiple protocol instances are be instantiated among others.

The goal of this document is to define a data model that provides a common user interface to the OSPFv2 and OSPFv3 protocols. There is very little information that is designated as "mandatory", providing freedom for vendors to adapt this data model to their respective product implementations.

2.1. OSPF Operational State

The OSPF operational state is included in the same tree as OSPF configuration consistent with the Network Management Datastore Architecture [RFC8342]. Consequently, only the routing container in the ietf-routing model [RFC8349] is augmented. The routing-state container is not augmented.

2.2. Overview

The OSPF YANG module defined in this document has all the common building blocks for the OSPF protocol.

The OSPF YANG module augments the /routing/control-plane-protocols/control-plane-protocol path defined in the ietf-routing module. The ietf-ospf model defines a single instance of OSPF which may be instantiated as an OSPFv2 or OSPFv3 instance. Multiple instances are instantiated as multiple control-plane protocols instances.

```

module: ietf-ospf
  augment /rt:routing/rt:control-plane-protocols/
    rt:control-plane-protocol:
      +--rw ospf
         .
         .
         +--rw af?                               identityref
            .
            .
            +--rw areas
               +--rw area* [area-id]
                  +--rw area-id                 area-id-type
                     .
                     .
                     +--rw virtual-links
                        +--rw virtual-link* [transit-area-id router-id]
                           .
                           .
                           +--rw sham-links {pe-ce-protocol}?
                              +--rw sham-link* [local-id remote-id]
                                 .
                                 .
                                 +--rw interfaces
                                    +--rw interface* [name]
                                       .
                                       .
            +--rw topologies {multi-topology}?
               +--rw topology* [name]
                  .
                  .

```

The ospf container includes one OSPF protocol instance. The instance includes OSPF router level configuration and operational state. Each OSPF instance maps to a control-plane-protcol instance as defined in [RFC8349].

The area and area/interface containers define the OSPF configuration and operational state for OSPF areas and interfaces respectively.

The topologies container defines the OSPF configuration and operational state for OSPF topologies when the multi-topology feature is supported.

2.3. OSPFv2 and OSPFv3

The data model defined herein supports both OSPFv2 and OSPFv3.

The field 'version' is used to indicate the OSPF version and is mandatory. Based on the configured version, the data model varies to accommodate the differences between OSPFv2 and OSPFv3.

2.4. Optional Features

Optional features are beyond the basic OSPF configuration and it is the responsibility of each vendor to decide whether to support a given feature on a particular device.

This model defines the following optional features:

1. multi-topology: Support Multi-Topology Routing (MTR) [RFC4915].
2. multi-area-adj: Support OSPF multi-area adjacency [RFC5185].
3. explicit-router-id: Support explicit per-instance Router-ID specification.
4. demand-circuit: Support OSPF demand circuits [RFC1793].
5. mtu-ignore: Support disabling OSPF Database Description packet MTU mismatch checking specified in section 10.6 of [RFC2328].
6. lls: Support OSPF link-local signaling (LLS) [RFC5613].
7. prefix-suppression: Support OSPF prefix advertisement suppression [RFC6860].
8. ttl-security: Support OSPF Time to Live (TTL) security check support [RFC5082].
9. nsr: Support OSPF Non-Stop Routing (NSR). The OSPF NSR feature allows a router with redundant control-plane capability (e.g., dual Route-Processor (RP) cards) to maintain its state and adjacencies during planned and unplanned control-plane processing restarts. It differs from graceful-restart or Non-

Stop Forwarding (NSF) in that no protocol signaling or assistance from adjacent OSPF neighbors is required to recover control-plane state.

10. graceful-restart: Support Graceful OSPF Restart [RFC3623], [RFC5187].
11. auto-cost: Support OSPF interface cost calculation according to reference bandwidth [RFC2328].
12. max-ecmp: Support configuration of the maximum number of Equal-Cost Multi-Path (ECMP) paths.
13. max-lsa: Support configuration of the maximum number of LSAs the OSPF instance will accept [RFC1765].
14. te-rid: Support configuration of the Traffic Engineering (TE) Router-ID, i.e., the Router Address described in Section 2.4.1 of [RFC3630] or the Router IPv6 Address TLV described in Section 3 of [RFC5329].
15. ldp-igp-sync: Support LDP IGP synchronization [RFC5443].
16. ospfv2-authentication-trailer: Support OSPFv2 Authentication trailer as specified in [RFC5709] or [RFC7474].
17. ospfv3-authentication-ipsec: Support IPsec for OSPFv3 authentication [RFC4552].
18. ospfv3-authentication-trailer: Support OSPFv3 Authentication trailer as specified in [RFC7166].
19. fast-reroute: Support IP Fast Reroute (IP-FRR) [RFC5714].
20. node-flag: Support node-flag for OSPF prefixes. [RFC7684].
21. node-tag: Support node admin tag for OSPF instances [RFC7777].
22. lfa: Support Loop-Free Alternates (LFAs) [RFC5286].
23. remote-lfa: Support Remote Loop-Free Alternates (R-LFA) [RFC7490].
24. stub-router: Support RFC 6987 OSPF Stub Router advertisement [RFC6987].
25. pe-ce-protocol: Support OSPF as a PE-CE protocol [RFC4577], [RFC6565].

26. ietf-spf-delay: Support IETF SPF delay algorithm [RFC8405].
27. bfd: Support BFD detection of OSPF neighbor reachability [RFC5880], [RFC5881], and [I-D.ietf-bfd-yang].
28. hybrid-interface: Support OSPF Hybrid Broadcast and Point-to-Point Interfaces [RFC6845].

It is expected that vendors will support additional features through vendor-specific augmentations.

2.5. OSPF Router Configuration/Operational State

The `ospf` container is the top-level container in this data model. It represents an OSPF protocol instance and contains the router level configuration and operational state. The operational state includes the instance statistics, IETF SPF delay statistics, AS-Scoped Link State Database, local RIB, SPF Log, and the LSA log.

```

2.8. OSPF Notifications

This YANG model defines a list of notifications that inform YANG clients of important events detected during protocol operation. The defined notifications cover the common set of traps from the OSPFv2 MIB [RFC4750] and OSPFv3 MIB [RFC5643].

```

notifications:
  +---n if-state-change
  |   +--ro routing-protocol-name?
  |   +   -> /rt:routing/control-plane-protocols/
  |   +   control-plane-protocol/name

```

2.9. OSPF RPC Operations

The "ietf-ospf" module defines two RPC operations:

- o clear-database: reset the content of a particular OSPF Link State Database.
- o clear-neighbor: Reset a particular OSPF neighbor or group of neighbors associated with an OSPF interface.

```

rpcs:
+---x clear-neighbor
|   +---w input
|   |   +---w routing-protocol-name
|   |   +   -> /rt:routing/control-plane-protocols/
|   |   +   control-plane-protocol/name
|   |   +---w interface?           if:interface-ref
+---x clear-database
|   +---w input
|   |   +---w routing-protocol-name
|   |   -> /rt:routing/control-plane-protocols/
|   |   control-plane-protocol/name

```

3. OSPF YANG Module

The following RFCs and drafts are not referenced in the document text but are referenced in the ietf-ospf.yang module: [RFC0905], [RFC4576], [RFC4973], [RFC5250], [RFC5309], [RFC5642], [RFC5881], [RFC6991], [RFC7770], [RFC7884], [RFC8294], and [RFC8476].

description  
  "This YANG module defines the generic configuration and  
  operational state for the OSPF protocol common to all  
  vendor implementations. It is intended that the module  
  will be extended by vendors to define vendor-specific  
  OSPF configuration parameters and policies,  
  for example, route maps or route policies.  
  
  This YANG model conforms to the Network Management  
  Datastore Architecture (NMDA) as described in RFC 8242.

4. Security Considerations

The YANG modules specified in this document define a schema for data that is designed to be accessed via network management protocols such as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF layer is the secure transport layer, and the mandatory-to-implement secure transport is Secure Shell (SSH) [RFC6242]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [RFC8446].

The NETCONF Access Control Model (NACM) [RFC8341] provides the means to restrict access for particular NETCONF or RESTCONF users to a pre-configured subset of all available NETCONF or RESTCONF protocol operations and content.

There are a number of data nodes defined in `ietf-ospf.yang` module that are writable/creatable/deletable (i.e., `config true`, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., `edit-config`) to these data nodes without proper protection can have a negative effect on network operations. Writable data node represent configuration of each instance, area, virtual link, sham-link, and interface. These correspond to the following schema nodes:

```
/ospf
/ospf/areas/
/ospf/areas/area[area-id]
/ospf/virtual-links/
/ospf/virtual-links/virtual-link[transit-area-id router-id]
/ospf/areas/area[area-id]/interfaces
/ospf/areas/area[area-id]/interfaces/interface[name]
/ospf/area/area[area-id]/sham-links
/ospf/area/area[area-id]/sham-links/sham-link[local-id remote-id]
```

For OSPF, the ability to modify OSPF configuration will allow the entire OSPF domain to be compromised including peering with unauthorized routers to misroute traffic or mount a massive Denial-of-Service (DoS) attack. For example, adding OSPF on any unprotected interface could allow an OSPF adjacency to be formed with an unauthorized and malicious neighbor. Once an adjacency is formed, traffic could be hijacked. As a simpler example, a Denial-of-Service attack could be mounted by changing the cost of an OSPF interface to be asymmetric such that a hard routing loop ensues. In general, unauthorized modification of most OSPF features will pose their own set of security risks and the "Security Considerations" in the respective reference RFCs should be consulted.

Some of the readable data nodes in the `ietf-ospf.yang` module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via `get`, `get-config`, or `notification`) to these data nodes. The exposure of the Link State Database (LSDB) will expose the detailed topology of the network. There is a separate Link State Database for each instance, area, virtual link, sham-link, and interface. These correspond to the following schema nodes:

```
/ospf/database  
  
/ospf/areas/area[area-id]/database  
  
/ospf/virtual-links/virtual-link[transit-area-id router-  
id]/database  
  
/ospf/areas/area[area-id]/interfaces/interface[name]/database  
  
/ospf/area/area[area-id]/sham-links/sham-link[local-id remote-  
id]/database
```

Exposure of the Link State Database includes information beyond the scope of the OSPF router and this may be undesirable since exposure may facilitate other attacks. Additionally, in the case of an area LSDB, the complete IP network topology and, if deployed, the traffic engineering topology of the OSPF area can be reconstructed. Network operators may consider their topologies to be sensitive confidential data.

For OSPF authentication, configuration is supported via the specification of key-chains [RFC8177] or the direct specification of key and authentication algorithm. Hence, authentication configuration using the "auth-table-trailer" case in the "authentication" container inherits the security considerations of [RFC8177]. This includes the considerations with respect to the local storage and handling of authentication keys.

Additionally, local specification of OSPF authentication keys and the associated authentication algorithm is supported for legacy implementations that do not support key-chains [RFC8177] It is RECOMMENDED that implementations migrate to key-chains due the seamless support of key and algorithm rollover, as well as, the hexadecimal key specification affording more key entropy, and encryption of keys using the Advanced Encryption Standard (AES) Key Wrap Padding Algorithm [RFC5649].

Some of the RPC operations in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control access to these operations. The OSPF YANG module supports the "clear-neighbor" and "clear-database" RPCs. If access to either of these is compromised, they can result in temporary network outages be employed to mount DoS attacks.

The actual authentication key data (whether locally specified or part of a key-chain) is sensitive and needs to be kept secret from unauthorized parties; compromise of the key data would allow an

attacker to forge OSPF traffic that would be accepted as authentic, potentially compromising the entirety OSPF domain.

5. IANA Considerations

This document registers a URI in the IETF XML registry [RFC3688]. Following the format in [RFC3688], the following registration is requested to be made:

```
URI: urn:ietf:params:xml:ns:yang:ietf-ospf
Registrant Contact: The IESG.
XML: N/A, the requested URI is an XML namespace.
```

This document registers a YANG module in the YANG Module Names registry [RFC6020].

```
name: ietf-ospf
namespace: urn:ietf:params:xml:ns:yang:ietf-ospf
prefix: ospf
reference: RFC XXXX
```

6. Acknowledgements

The authors wish to thank Yi Yang, Alexander Clemm, Gaurav Gupta, Ladislav Lhotka, Stephane Litkowski, Greg Hankins, Manish Gupta and Alan Davey for their thorough reviews and helpful comments.

Thanks to Tom Petch for last call review and improvement of the document organization.

Thanks to Alvaro Retana for AD comments.

Thanks to Benjamin Kaduk, Suresh Krishnan, and Roman Dannyliw for IESG review comments.

This document was produced using Marshall Rose's xml2rfc tool.

OSPFv2 Link Traffic Engineering (TE) Attribute Reuse
draft-psenak-ospf-te-link-attr-reuse-05.txt

Abstract

Various link attributes have been defined in OSPFv2 in the context of the MPLS Traffic Engineering (TE) and GMPLS. Many of these link attributes can be used for purposes other than MPLS Traffic Engineering or GMPLS. This document defines how to distribute such attributes in OSPFv2 for applications other than MPLS Traffic Engineering or GMPLS purposes.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on December 25, 2017.

1. Introduction

Various link attributes have been defined in OSPFv2 [RFC2328] in the context of the MPLS traffic engineering and GMPLS. All these attributes are distributed by OSPFv2 as sub-TLVs of the Link-TLV advertised in the OSPFv2 TE Opaque LSA [RFC3630].

Many of these link attributes are useful outside of the traditional MPLS Traffic Engineering or GMPLS. This brings its own set of problems, in particular how to distribute these link attributes in OSPFv2 when MPLS TE or GMPLS are not deployed or are deployed in parallel with other applications that use these link attributes.

[RFC7855] discusses use cases/requirements for SR. Included among these use cases is SRTE. If both RSVP-TE and SRTE are deployed in a network, link attribute advertisements can be used by one or both of these applications. As there is no requirement for the link attributes advertised on a given link used by SRTE to be identical to the link attributes advertised on that same link used by RSVP-TE, there is a clear requirement to indicate independently which link attribute advertisements are to be used by each application.

As the number of applications which may wish to utilize link attributes may grow in the future, an additional requirement is that the extensions defined allow the association of additional applications to link attributes without altering the format of the advertisements or introducing new backwards compatibility issues.

Finally, there may still be many cases where a single attribute value can be shared among multiple applications, so the solution should minimize advertising duplicate link/attribute when possible.

1.1. Requirements notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

2. Link attributes examples

This section lists some of the link attributes originally defined for MPLS Traffic Engineering that can be used for other purposes in OSPFv2. The list doesn't necessarily contain all the required attributes.

1. Remote Interface IP address [RFC3630] - OSPFv2 currently cannot distinguish between parallel links between two OSPFv2 routers. As a result, the two-way connectivity check performed during SPF

may succeed when the two routers disagree on which of the links to use for data traffic.

2. Link Local/Remote Identifiers - [RFC4203] - Used for the two-way connectivity check for parallel unnumbered links. Also used for identifying adjacencies for unnumbered links in Segment Routing traffic engineering.
 3. Shared Risk Link Group (SRLG) [RFC4203] - In IPFRR, the SRLG is used to compute diverse backup paths [RFC5714].
 4. Unidirectional Link Delay/Loss Metrics [RFC7471] - Could be used for the shortest path first (SPF) computation using alternate metrics within an OSPF area.
3. Advertising Link Attributes

This section outlines possible approaches for advertising link attributes originally defined for MPLS Traffic Engineering purposes or GMPLS when they are used for other applications.

3.1. TE Opaque LSA

One approach for advertising link attributes is to continue to use TE Opaque LSA ([RFC3630]). There are several problems with this approach:

1. Whenever the link is advertised in a TE Opaque LSA, the link becomes a part of the TE topology, which may not match IP routed topology. By making the link part of the TE topology, remote nodes may mistakenly believe that the link is available for MPLS TE or GMPLS, when, in fact, MPLS is not enabled on the link.
2. The TE Opaque LSA carries link attributes that are not used or required by MPLS TE or GMPLS. There is no mechanism in a TE Opaque LSA to indicate which of the link attributes are passed to MPLS TE application and which are used by other applications including OSPFv2 itself.
3. Link attributes used for non-TE purposes are partitioned across multiple LSAs - the TE Opaque LSA and the Extended Link Opaque LSA. This partitioning will require implementations to lookup multiple LSAs to extract link attributes for a single link, bringing needless complexity to OSPFv2 implementations.

The advantage of this approach is that there is no additional standardization requirement to advertise the TE/GMPL attributes for other applications. Additionally, link attributes are only

advertised once when both OSPF TE and other applications are deployed on the same link. This is not expected to be a common deployment scenario.

3.2. Extended Link Opaque LSA

An alternative approach for advertising link attributes is to use Extended Link Opaque LSAs as defined in [RFC7684]. This LSA was defined as a generic container for distribution of the extended link attributes. There are several advantages in using Extended Link LSA:

1. Advertisement of the link attributes does not make the link part of the TE topology. It avoids any conflicts and is fully compatible with the [RFC3630].
2. The TE Opaque LSA remains truly opaque to OSPFv2 as originally defined in [RFC3630]. Its content is not inspected by OSPFv2 and OSPFv2 acts as a pure transport.
3. There is clear distinction between link attributes used by TE and link attributes used by other OSPFv2 applications.
4. All link attributes that are used by OSPFv2 applications are advertised in a single LSA, the Extended Link Opaque LSA.

The disadvantage of this approach is that in rare cases, the same link attribute is advertised in both the TE Opaque and Extended Link Attribute LSAs. Additionally, there will be additional standardization effort. However, this could also be viewed as an advantage as the non-TE use cases for the TE link attributes are documented and validated by the OSPF working group.

3.3. Selected Approach

It is RECOMMENDED to use the Extended Link Opaque LSA ([RFC7684] to advertise any link attributes used for non-TE purposes in OSPFv2, including those that have been originally defined for TE purposes. TE link attributes used for TE purposes continue to use TE Opaque LSA ([RFC3630]).

It is also RECOMMENDED to keep the format of the link attribute TLVs that have been defined for TE purposes unchanged even when they are used for non-TE purposes.

Finally, it is RECOMMENDED to allocate unique code points for link attribute TLVs that have been defined for TE purposes for the OSPFv2 Extended Link TLV Sub-TLV Registry as defined in [RFC7684]. For each

reused TLV, the code point will be defined in an IETF document along with the expected usecase(s).

4. Reused TE link attributes

This section defines the use case and code points for the OSPFv2 Extended Link TLV Sub-TLV Registry for some of the link attributes that have been originally defined for TE or GMPLS purposes.

4.1. Remote interface IP address

The OSPFv2 description of an IP numbered point-to-point adjacency does not include the remote IP address. As described in Section 2, this makes the two-way connectivity check ambiguous in the presence of the parallel point-to-point links between two OSPFv2 routers.

The Remote IP address of the link can also be used for Segment Routing traffic engineering to identify the link in a set of parallel links between two OSPFv2 routers [I-D.ietf-ospf-segment-routing-extensions]. Similarly, the remote IP address is useful in identifying individual parallel OSPF links advertised in BGP Link-State as described in [I-D.ietf-idr-ls-distribution].

To advertise the Remote interface IP address in the OSPFv2 Extended Link TLV, the same format of the sub-TLV as defined in section 2.5.4. of [RFC3630] is used and TLV type TBD1 is used.

4.2. Link Local/Remote Identifiers

The OSPFv2 description of an IP unnumbered point-to-point adjacency does not include the remote link identifier. As described in Section 2, this makes the two-way connectivity check ambiguous in the presence of the parallel point-to-point IP unnumbered links between two OSPFv2 routers.

The local and remote link identifiers can also be used for Segment Routing traffic engineering to identify the link in a set of parallel IP unnumbered links between two OSPFv2 routers [I-D.ietf-ospf-segment-routing-extensions]. Similarly, these identifiers are useful in identifying individual parallel OSPF links advertised in BGP Link-State as described in [I-D.ietf-idr-ls-distribution].

To advertise the link Local/Remote identifiers in the OSPFv2 Extended Link TLV, the same format of the sub-TLV as defined in section 1.1. of [RFC4203] is used and TLV type TBD2 is used.

4.3. Shared Risk Link Group (SRLG)

The SRLG of a link can be used in IPFRR to compute a backup path that does not share any SRLG group with the protected link.

To advertise the SRLG of the link in the OSPFv2 Extended Link TLV, the same format of the sub-TLV as defined in section 1.3. of [RFC4203] is used and TLV type TBD3 is used.

4.4. Extended Metrics

[RFC3630] defines several link bandwidth types. [RFC7471] defines extended link metrics that are based on link bandwidth, delay and loss characteristics. All these can be used to compute best paths within an OSPF area to satisfy requirements for bandwidth, delay (nominal or worst case) or loss.

To advertise extended link metrics in the OSPFv2 Extended Link TLV, the same format of the sub-TLVs as defined in [RFC7471] is used with following TLV types:

- TBD4 - Unidirectional Link Delay
- TBD5 - Min/Max Unidirectional Link Delay
- TBD6 - Unidirectional Delay Variation
- TBD7 - Unidirectional Link Loss
- TBD8 - Unidirectional Residual Bandwidth
- TBD9 - Unidirectional Available Bandwidth
- TBD10 - Unidirectional Utilized Bandwidth

5. Advertisement of Application Specific Values

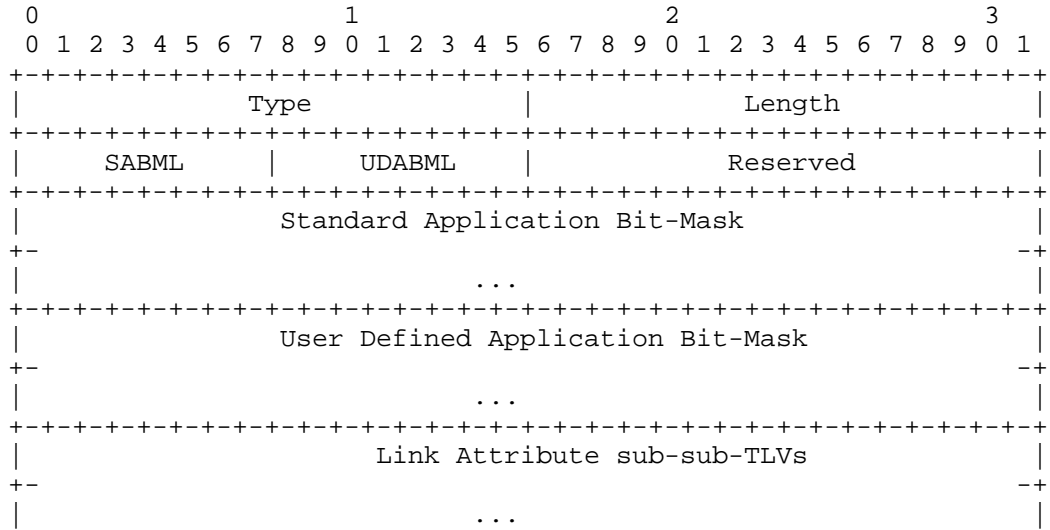

Multiple applications can utilize link attributes that are flooded by OSPFv2. Some examples of applications using the link attributes are Segment Routing Traffic Engineering and LFA [RFC5286].

In some cases the link attribute only has a single value that is applicable to all applications. An example is a Remote interface IP address [Section 4.1] or Link Local/Remote Identifiers [Section 4.2].

In some cases the link attribute MAY have different values for different applications. An example could be SRLG [Section 4.3],

where values used by LFA could be different then the values used by Segment Routing Traffic Engineering.

To allow advertisement of the application specific values of the link attribute, a new Extended Link Attribute sub-TLV of the Extended Link TLV [RFC7471] is defined. The Extended Link Attribute sub-TLV is an optional sub-TLV and can appear multiple times in the Extended Link TLV. It has following format:

where:

Type: TBD11, suggested value 14

Length: variable

SABML: Standard Application Bit-Mask Length. If the Standard Application Bit-Mask is not present, the Standard Application Bit-Mask Length MUST be set to 0.

UDABML: User Defined Application Bit-Mask Length. If the User Defined Application Bit-Mask is not present, the User Defined Application Bit-Mask Length MUST be set to 0.

Standard Application Bit-Mask: Optional set of bits, where each bit represents a single standard application. The following bits are defined by this document:

Bit-0: RSVP Traffic Engineering

Bit-1: Segment Routing Traffic Engineering

Bit-2: Loop Free Alternate (LFA). Includes all LFA types.

User Defined Application Bit-Mask: Optional set of bits, where each bit represents a single user defined application.

Standard Application Bits are defined/sent starting with Bit 0. Additional bit definitions that may be defined in the future SHOULD be assigned in ascending bit order so as to minimize the number of octets that will need to be transmitted.

User Defined Application bits have no relationship to Standard Application bits and are NOT managed by IANA or any other standards body. It is recommended that bits are used starting with Bit 0 so as to minimize the number of octets required to advertise all of them.

Undefined bits in both Bit-Masks MUST be transmitted as 0 and MUST be ignored on receipt. Bits that are NOT transmitted MUST be treated as if they are set to 0 on receipt.

If the link attribute advertisement is limited to be used by a specific set of applications, corresponding Bit-Masks MUST be present and application specific bit(s) MUST be set for all applications that use the link attributes advertised in the Extended Link Attribute sub-TLV.

Application Bit-Masks apply to all link attributes that support application specific values and are advertised in the Extended Link Attribute sub-TLV.

The advantage of not making the Application Bit-Masks part of the attribute advertisement itself is that we can keep the format of the link attributes that have been defined previously and reuse the same format when advertising them in the Extended Link Attribute sub-TLV.

If the link attribute is advertised and there is no Application Bit-Mask present in the Extended Link Attribute Sub-TLV, the link attribute advertisement MAY be used by any application. If, however, another advertisement of the same link attribute includes any Application Bit-Mask in the Extended Link Attribute sub-TLV, applications that are listed in the Application Bit-Masks of such Extended Link Attribute sub-TLV SHOULD use the attribute advertisement which has the application specific bit set in the Application Bit-Masks.

If the same application is listed in the Application Bit-Masks of more than one Extended Link Attribute sub-TLV, the application SHOULD

use the first advertisement and ignore any subsequent advertisements of the same attribute. This situation SHOULD be logged as an error.

This document defines the set of link attributes for which the Application Bit-Masks may be advertised. If any of the Application Bit-Masks is included in the Extended Link Attribute sub-TLV that advertises any link attribute(s) NOT listed below, the Application Bit-Masks MUST NOT be used for such link attribute(s). It MUST be used for those attribute(s) that support application specific values. Documents which define new link attributes MUST state whether the new attributes support application specific values. The link attributes to which the Application Bit-Masks may apply are:

- Shared Risk Link Group
- Unidirectional Link Delay
- Min/Max Unidirectional Link Delay
- Unidirectional Delay Variation
- Unidirectional Link Loss
- Unidirectional Residual Bandwidth
- Unidirectional Available Bandwidth
- Unidirectional Utilized Bandwidth

6. Deployment Considerations

If link attributes are advertised associated with zero length application bit masks for both standard applications and user defined applications, then that set of link attributes MAY be used by any application. If support for a new application is introduced on any node in a network in the presence of such advertisements, these advertisements MAY be used by the new application. If this is not what is intended, then existing advertisements MUST be readvertised with an explicit set of applications specified before a new application is introduced.

7. Attribute Advertisements and Enablement

This document defines extensions to support the advertisement of application specific link attributes. The presence or absence of link attribute advertisements for a given application on a link does NOT indicate the state of enablement of that application on that

link. Enablement of an application on a link is controlled by other means.

For some applications, the concept of enablement is implicit. For example, SRTE implicitly is enabled on all links which are part of the Segment Routing enabled topology. Advertisement of link attributes supports constraints which may be applied when specifying an explicit path through that topology.

For other applications enablement is controlled by local configuration. For example, use of a link as an LFA can be controlled by local enablement/disablement and/or the use of administrative tags.

It is an application specific policy as to whether a given link can be used by that application even in the absence of any application specific link attributes.

8. Backward Compatibility

Link attributes may be concurrently advertised in both the TE Opaque LSA [RFC3630] and the Extended Link Opaque LSA [RFC7684].

In fact, there is at least one OSPF implementation that utilizes the link attributes advertised in TE Opaque LSAs [RFC3630] for Non-RSVP TE applications. For example, this implementation of LFA and remote LFA utilizes links attributes such as Shared Risk Link Groups (SRLG) [RFC4203] and Admin Group [[RFC3630]advertised in TE Opaque LSAs. These applications are described in [RFC5286], [RFC7490], [I-D.ietf-rtgwg-lfa-manageability] and [I-D.psarkar-rtgwg-rlfa-node-protection].

When an OSPF routing domain includes routers using link attributes from TE Opaque LSAs for Non-RSVP TE applications such as LFA, OSPF routers in that domain should continue to advertise such TE Opaque LSAs. If there are also OSPF routers using the link attributes described herein for any application, OSPF routers in the routing domain will also need to advertise these attributes in OSPF Extended Link Attributes LSAs [RFC7684]. In such a deployment, the advertised attributes SHOULD be the same and Non-RSVP application access to link attributes is a matter of local policy.

9. Security Considerations

Implementations must assure that malformed TLV and Sub-TLV permutations do not result in errors that cause hard OSPFv2 failures.

10. IANA Considerations

OSPFv2 Extended Link TLV Sub-TLVs registry [RFC7684] defines sub-TLVs at any level of nesting for OSPFv2 Extended Link TLVs. This specification updates OSPFv2 Extended Link TLV sub-TLVs registry with the following TLV types:

- TBD1 (4 Recommended) - Remote interface IP address
- TBD2 (5 Recommended) - Link Local/Remote Identifiers
- TBD3 (6 Recommended) - Shared Risk Link Group
- TBD4 (7 Recommended) - Unidirectional Link Delay
- TBD5 (8 Recommended) - Min/Max Unidirectional Link Delay
- TBD6 (9 Recommended) - Unidirectional Delay Variation
- TBD7 (10 Recommended) - Unidirectional Link Loss
- TBD8 (11 Recommended) - Unidirectional Residual Bandwidth
- TBD9 (12 Recommended) - Unidirectional Available Bandwidth
- TBD10 (13 Recommended) - Unidirectional Utilized Bandwidth
- TBD11 (14 Recommended) - Extended Link Attribute

This specification defines a new Link-Attribute-Applicability Application Bits registry and defines following bits:

- Bit-0 - Segment Routing Traffic Engineering
- Bit-1 - LFA
