Optimal Service Placement using Pseudo Service Chaining Mechanism

[Playnet-MANO]

2016. 11. 15.

Taeheum Na : {taeheum@etri.re.kr}
Network SW Platform Research Section

ETRI

❖ Background

- Playnet-MANO

❖ PSCM : **P**seudo **S**ervice **C**haining **M**echanism

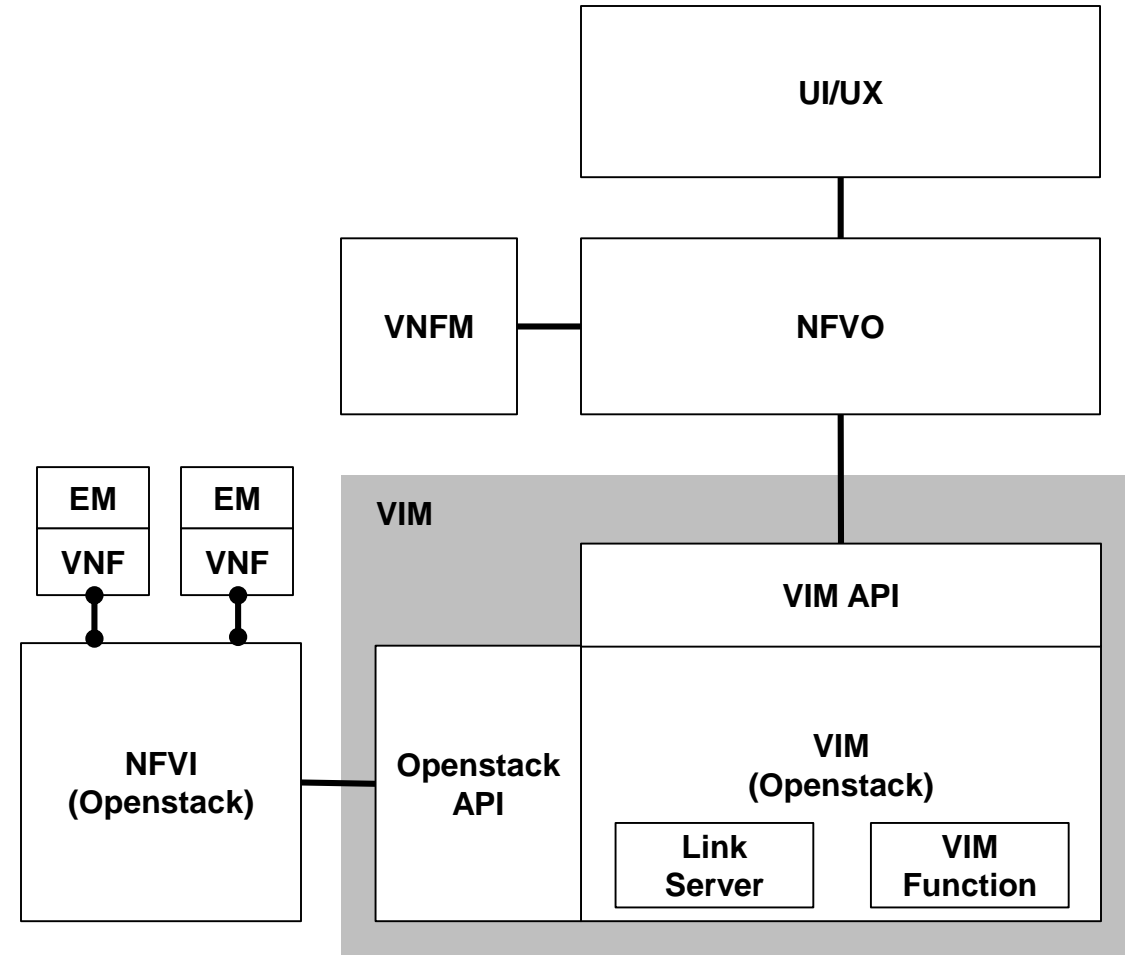

- Phase 1: Calculation of virtual link cost
- Phase 2: Selection of available computing nodes
- Phase 3: Greedy placement

❖ Conclusion

Playnet-MANO

❖ Playnet-MANO = Playground for virtualized network application

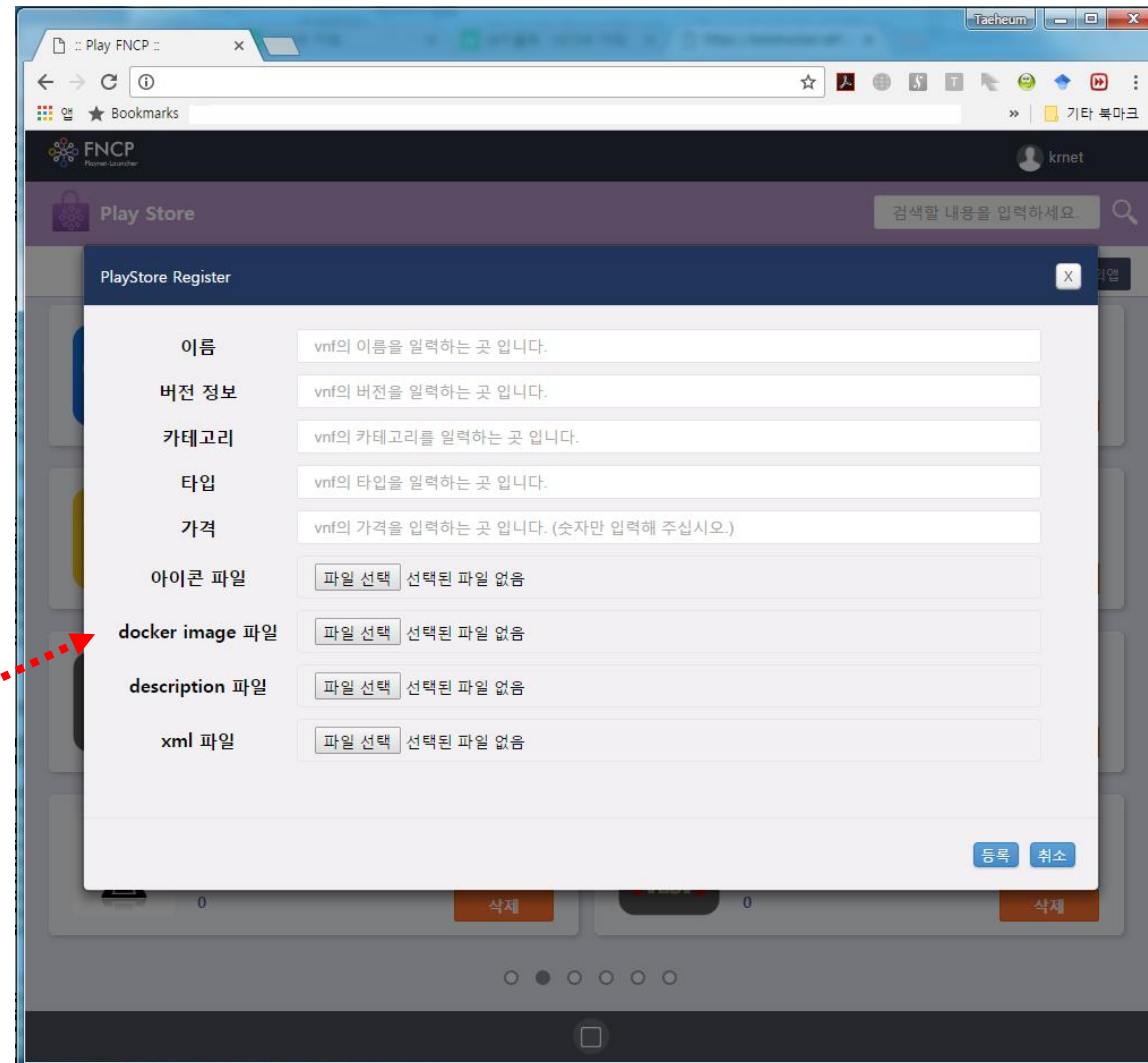

- Open Source MANO (OSM) based NFV Environment
- Extended VIM functionality: OpenStack (liberty)
 - Container and KVM based virtualization
 - Using Nova-docker plugin
 - Consideration for point-to-point link (E-line type)
- Saving & loading Network Service (NS)
 - Save and load NS using VNFFG format

ETRI Playnet Architecture

❖ Features of Playnet

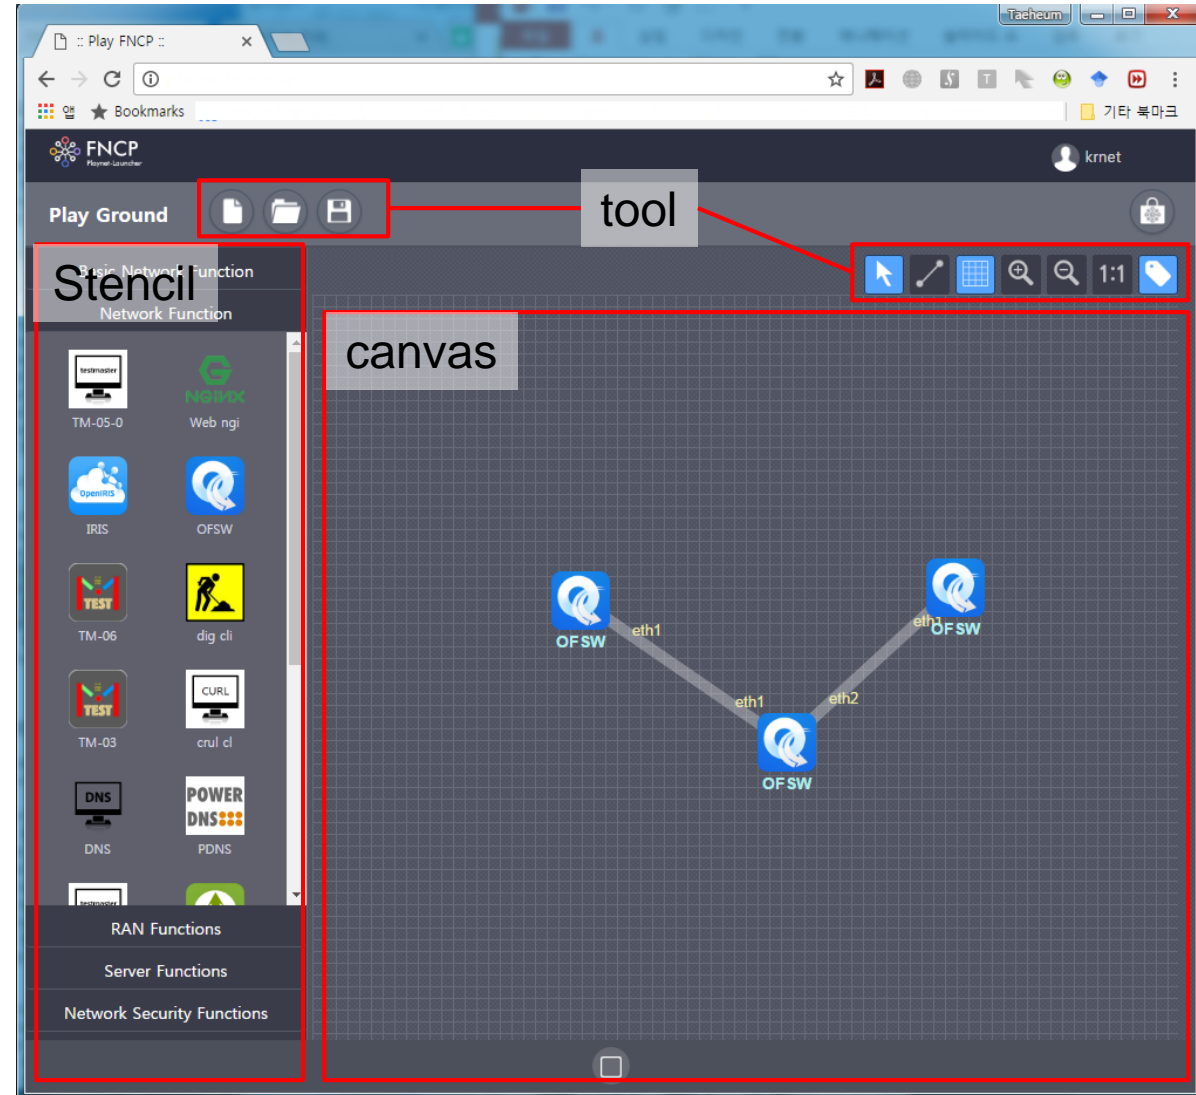

- VNF Management
 - GUI based Registering / deleting VNF at Playnet Store
 - Instantiation/termination/configuration

ETRI Playnet Architecture

❖ Features of Playnet

- Network Service Management
 - Network Services are managed as projects
 - Project save → configuration for VNFs are also saved
 - Loading the project → all VNF instances are activated
 - ✓ Configurations for VNFs are also synchronized
 - Project termination → all VNF instances are terminated
- Creating/deleting link among VNFs
 - Point-to-Point, Multipoint-to-Multipoint
- Flavor management
- → When NS is loaded, need to consider optimal placement for the link performance

Related work

❖ IETF Standard

- draft-irtf-nfvrg-resource-management-service-chain-03
- draft-lee-sfc-dynamic-instantiation-01
- Both draft document mention traffic localization
 - ➔ Our work can be one of the use case

❖ ETSI Standard

- VNFFG Descriptor (VNFFGD)
 - Virtual Link Descriptor (VLD)
 - Throughput/Bandwidth requirement, QoS
 - Virtual Link Record (VLR)
 - Allocated_capacity
- ➔ need more specific parameter for the link
- number of transaction (VLD), weight of transaction (VLD), amount of transmitted data (VLR)

Pseudo Service Chaining Mechanism

Pseudo Service Chaining Mechanism

❖ Goal

- By localizing SFs (=Minimize the number of entity in SFPs) based on link description metric
- Saving core network bandwidth
- By avoiding capsulation, save the computation resource
- Getting more better performance of virtual link

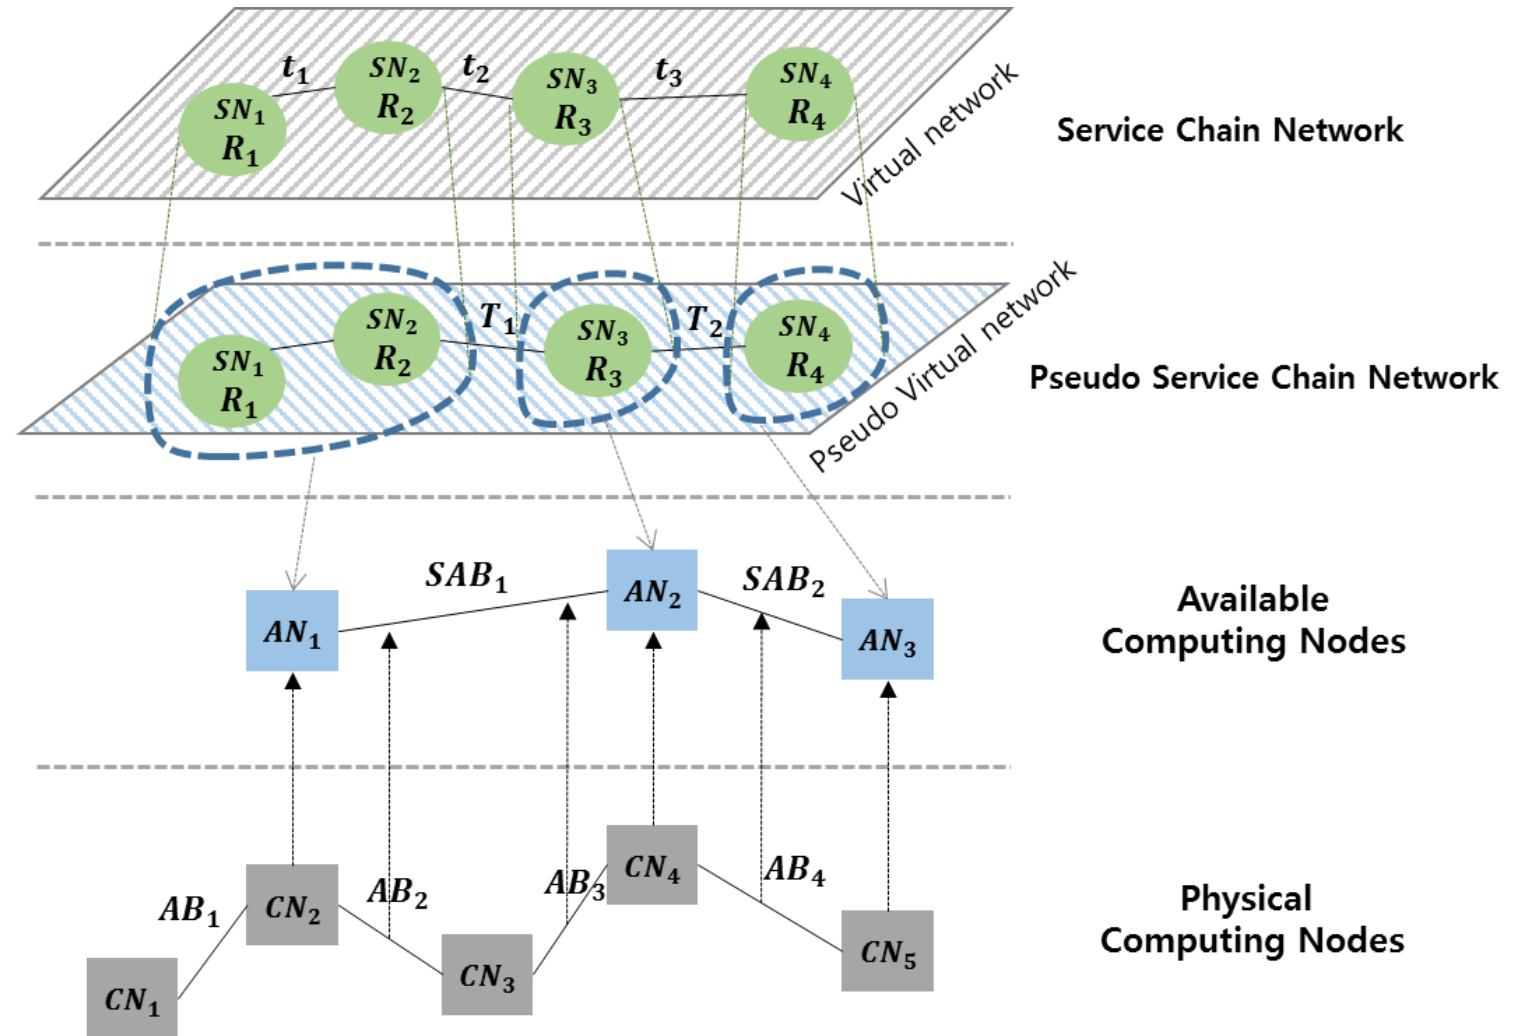

❖ Assumption

- Doesn't consider scaling, failover and policy
- Metric of Link parameter is decided by Operator (SFC user) at first
- Based on monitoring, it can be updated

Pseudo Service Chaining Mechanism

❖ Overview of mechanism

- Phase 1: Calculation of Virtual Link Costs
 - Based on VLD parameters calculate link cost
 - Selecting pseudo virtual node (PVN)
- Phase 2: selection of available computing nodes
- Phase 3: Placement PVN
- It is recursively conducted

Pseudo Service Chaining Mechanism

❖ Phase 1: Calculation of Virtual Link Costs

- Transaction among service nodes
- Transaction weight at virtual link
- Volume of traffic at virtual link

$$c_i = w_i \times NRROM(t_i) \times b_i$$

where, $0 < i < \text{number of virtual link}$

Table 1. Parameter definitions for calculation of virtual link costs.

Notation	Definition
t_i	Amount of transactions at a virtual link i
w_i	Transaction weight for a virtual link i
b_i	Volume of traffic at a virtual link i
c_i	Cost of a virtual link i
L_c	List of virtual links in the order of cost

Pseudo Service Chaining Mechanism

❖ Phase 2: Selection of available computing nodes

- Based on resource requirement of instance
- Available compute node

➤ 1st available compute node

- ✓ Available resource > resource requirement of PVN

$L_r = \text{List of Available computing Nodes } \{R_i \geq \text{SUM}[V_{r_i}, V_{r_{i+1}}]\}$

Where, $0 < i < \text{number of service node}$

➤ 2nd available compute node

- ✓ Available resource > minimum resource requirement of SN

$L_r = \text{List of Available computing Nodes } \{R_i \geq \text{MIN}[V_{r_1}, V_{r_i}]\}$

Where, $0 < i < \text{number of service node}$

- Sort in descending order

Pseudo Service Chaining Mechanism

❖ Phase 3: Greedy placement

- Multiple-Knapsack Problem

$$x_{jk} \begin{cases} 1, \text{ if } vm_j \text{ is assigned in } pvm_k \\ 0, \text{ otherwise} \end{cases} \quad (5)$$

$$\sum_{j=1}^n Vr_j x_{jk} < R_i \quad (6)$$

$$pw_k = \sum_{j=1}^n w_j x_{jk} \quad (7)$$

$$y_{ik} \begin{cases} 1, \text{ if } pvm_k \text{ is assigned in } AN_i \\ 0, \text{ otherwise} \end{cases} \quad (8)$$

$$\text{maximizes } z = \sum_{i=1}^m \sum_{j=1}^n pw_k y_{ik} \quad (9)$$

Pseudo Service Chaining Mechanism

❖ Phase 3: Greedy placement

- Maximize the sum of cost in the allocated PVM

if, $AR_2 > (R_2 + R_3)$
 $AR_2 < (R_1 + R_2 + R_3)$

if, $AR_2 > (R_2 + R_3)$

Conclusion

❖ Result

- improvement of 14% in RTT
- improvement of 37% in UDP receive rate

❖ Analysis

- Better performance for Loss-rate of UDP
- Decrease round trip time
- Less CPU usage of host node(Interrupt)
