Cache Digests for HTTP/2  
draft-ietf-httpbis-cache-digest-01

Abstract

This specification defines a HTTP/2 frame type to allow clients to inform the server of their cache's contents. Servers can then use this to inform their choices of what to push to clients.

Note to Readers

Discussion of this draft takes place on the HTTP working group mailing list ([ietf-http-wg@w3.org](mailto:ietf-http-wg@w3.org)), which is archived at <https://lists.w3.org/Archives/Public/ietf-http-wg/> .

Working Group information can be found at <http://httpwg.github.io/> ; source code and issues list for this draft can be found at <https://github.com/httpwg/http-extensions/labels/cache-digest> .

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 5, 2017.

## 1. Introduction

HTTP/2 [RFC7540] allows a server to "push" synthetic request/response pairs into a client's cache optimistically. While there is strong interest in using this facility to improve perceived Web browsing performance, it is sometimes counterproductive because the client might already have cached the "pushed" response.

When this is the case, the bandwidth used to "push" the response is effectively wasted, and represents opportunity cost, because it could be used by other, more relevant responses. HTTP/2 allows a stream to be cancelled by a client using a RST\_STREAM frame in this situation, but there is still at least one round trip of potentially wasted capacity even then.

This specification defines a HTTP/2 frame type to allow clients to inform the server of their cache's contents using a Golomb-Rice Coded Set [Rice]. Servers can then use this to inform their choices of what to push to clients.

### 1.1. Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

## 2. The CACHE\_DIGEST Frame

The CACHE\_DIGEST frame type is 0xf1. NOTE: This is an experimental value; if standardised, a permanent value will be assigned.

```

+-----+-----+
|          Origin-Len (16)          | Origin? (\*)          ...
+-----+-----+
|                                | Digest-Value? (\*)      ...
+-----+-----+

```

The CACHE\_DIGEST frame payload has the following fields:

**Origin-Len:** An unsigned, 16-bit integer indicating the length, in octets, of the Origin field.

**Origin:** A sequence of characters containing the ASCII serialization of an origin ([RFC6454], Section 6.2) that the Digest-Value applies to.

**Digest-Value:** A sequence of octets containing the digest as computed in Section 2.1.1.

The CACHE\_DIGEST frame defines the following flags:

- o **\*RESET\*** (0x1): When set, indicates that any and all cache digests for the applicable origin held by the recipient MUST be considered invalid.
- o **\*COMPLETE\*** (0x2): When set, indicates that the currently valid set of cache digests held by the server constitutes a complete representation of the cache's state regarding that origin, for the type of cached response indicated by the "STALE" flag.
- o **\*VALIDATORS\*** (0x4): When set, indicates that the "validators" boolean in Section 2.1.1 is true.
- o **\*STALE\*** (0x8): When set, indicates that all cached responses represented in the digest-value are stale [RFC7234] at the point in them that the digest was generated; otherwise, all are fresh.

## 2.1. Client Behavior

A `CACHE_DIGEST` frame **MUST** be sent from a client to a server on stream 0, and conveys a digest of the contents of the client's cache for the indicated origin.

In typical use, a client will send one or more `CACHE_DIGESTS` immediately after the first request on a connection for a given origin, on the same stream, because there is usually a short period of inactivity then, and servers can benefit most when they understand the state of the cache before they begin pushing associated assets (e.g., CSS, JavaScript and images). Clients **MAY** send `CACHE_DIGEST` at other times.

If the cache's state is cleared, lost, or the client otherwise wishes the server to stop using previously sent `CACHE_DIGESTS`, it can send a `CACHE_DIGEST` with the `RESET` flag set.

When generating `CACHE_DIGEST`, a client **MUST NOT** include cached responses whose URLs do not share origins [RFC6454] with the indicated origin. Clients **MUST NOT** send `CACHE_DIGEST` frames on connections that are not authoritative (as defined in [RFC7540], 10.1) for the indicated origin.

`CACHE_DIGEST` allows the client to indicate whether the set of URLs used to compute the digest represent fresh or stale stored responses, using the `STALE` flag. Clients **MAY** decide whether to only sent `CACHE_DIGEST` frames representing their fresh stored responses, their stale stored responses, or both.

Clients can choose to only send a subset of the suitable stored responses of each type (fresh or stale). However, when the `CACHE_DIGEST` frames sent represent the complete set of stored responses of a given type, the last such frame **SHOULD** have a `COMPLETE` flag set, to indicate to the server that it has all relevant state of that type. Note that for the purposes of `COMPLETE`, responses cached since the beginning of the connection or the last `RESET` flag on a `CACHE_DIGEST` frame need not be included.

`CACHE_DIGEST` can be computed to include cached responses' ETags, as indicated by the `VALIDATORS` flag. This information can be used by servers to decide what kinds of responses to push to clients; for example, a stale response that hasn't changed could be refreshed with a 304 (Not Modified) response; one that has changed can be replaced with a 200 (OK) response, whether the cached response was fresh or stale.

CACHE\_DIGEST has no defined meaning when sent from servers, and SHOULD be ignored by clients.

#### 2.1.1.1. Computing the Digest-Value

Given the following inputs:

- o "validators", a boolean indicating whether validators ([RFC7232]) are to be included in the digest;
- o "URLs'", an array of (string "URL", string "ETag") tuples, each corresponding to the Effective Request URI ([RFC7230], Section 5.5) of a cached response [RFC7234] and its entity-tag [RFC7232] (if "validators" is true and if the ETag is available; otherwise, null);
- o "P", an integer that MUST be a power of 2 smaller than  $2^{32}$ , that indicates the probability of a false positive that is acceptable, expressed as "1/P".

"digest-value" can be computed using the following algorithm:

1. Let N be the count of "URLs'" members, rounded to the nearest power of 2 smaller than  $2^{32}$ .
2. Let "hash-values" be an empty array of integers.
3. For each ("URL", "ETag") in "URLs", compute a hash value (Section 2.1.2) and append the result to "hash-values".
4. Sort "hash-values" in ascending order.
5. Let "digest-value" be an empty array of bits.
6. Write log base 2 of "N" to "digest-value" using 5 bits.
7. Write log base 2 of "P" to "digest-value" using 5 bits.
8. Let "C" be -1.
9. For each "V" in "hash-values":
  1. If "V" is equal to "C", continue to the next "V".
  2. Let "D" be the result of "V - C - 1".
  3. Let "Q" be the integer result of "D / P".

4. Let "R" be the result of "D modulo P".
  5. Write "Q" '0' bits to "digest-value".
  6. Write 1 '1' bit to "digest-value".
  7. Write "R" to "digest-value" as binary, using  $\log_2("P")$  bits.
  8. Let "C" be "V"
10. If the length of "digest-value" is not a multiple of 8, pad it with 0s until it is.

#### 2.1.2. Computing a Hash Value

Given:

- o "URL", an array of characters
- o "ETag", an array of characters
- o "validators", a boolean
- o "N", an integer
- o "P", an integer

"hash-value" can be computed using the following algorithm:

1. Let "key" be "URL" converted to an ASCII string by percent-encoding as appropriate [RFC3986].
2. If "validators" is true and "ETag" is not null:
  1. Append "ETag" to "key" as an ASCII string, including both the "weak" indicator (if present) and double quotes, as per [RFC7232] Section 2.3.
3. Let "hash-value" be the SHA-256 message digest [RFC6234] of "key", expressed as an integer.
4. Truncate "hash-value" to  $\log_2("N" * "P")$  bits.

#### 2.2. Server Behavior

In typical use, a server will query (as per Section 2.2.1) the CACHE\_DIGESTs received on a given connection to inform what it pushes to that client;

- o If a given URL has a match in a current CACHE\_DIGEST with the STALE flag unset, it need not be pushed, because it is fresh in cache;
- o If a given URL and ETag combination has a match in a current CACHE\_DIGEST with the STALE flag set, the client has a stale copy in cache, and a validating response can be pushed;
- o If a given URL has no match in any current CACHE\_DIGEST, the client does not have a cached copy, and a complete response can be pushed.

Servers MAY use all CACHE\_DIGESTs received for a given origin as current, as long as they do not have the RESET flag set; a CACHE\_DIGEST frame with the RESET flag set MUST clear any previously stored CACHE\_DIGESTs for its origin. Servers MUST treat an empty Digest-Value with a RESET flag set as effectively clearing all stored digests for that origin.

Clients are not likely to send updates to CACHE\_DIGEST over the lifetime of a connection; it is expected that servers will separately track what cacheable responses have been sent previously on the same connection, using that knowledge in conjunction with that provided by CACHE\_DIGEST.

Servers MUST ignore CACHE\_DIGEST frames sent on a stream other than 0.

#### 2.2.1. Querying the Digest for a Value

Given:

- o "digest-value", an array of bits
- o "URL", an array of characters
- o "ETag", an array of characters
- o "validators", a boolean

we can determine whether there is a match in the digest using the following algorithm:

1. Read the first 5 bits of "digest-value" as an integer; let "N" be two raised to the power of that value.
2. Read the next 5 bits of "digest-value" as an integer; let "P" be two raised to the power of that value.

3. Let "hash-value" be the result of computing a hash value (Section 2.1.2).
4. Let "C" be -1.
5. Read '0' bits from "digest-value" until a '1' bit is found; let "Q" be the number of '0' bits. Discard the '1'.
6. Read  $\log_2("P")$  bits from "digest-value" after the '1' as an integer; let "R" be its value.
7. Let "D" be "Q" \* "P" + "R".
8. Increment "C" by "D" + 1.
9. If "C" is equal to "hash-value", return 'true'.
10. Otherwise, return to step 5 and continue processing; if no match is found before "digest-value" is exhausted, return 'false'.

### 3. IANA Considerations

This draft currently has no requirements for IANA. If the CACHE\_DIGEST frame is standardised, it will need to be assigned a frame type.

### 4. Security Considerations

The contents of a User Agent's cache can be used to re-identify or "fingerprint" the user over time, even when other identifiers (e.g., Cookies [RFC6265]) are cleared.

CACHE\_DIGEST allows such cache-based fingerprinting to become passive, since it allows the server to discover the state of the client's cache without any visible change in server behaviour.

As a result, clients MUST mitigate for this threat when the user attempts to remove identifiers (e.g., "clearing cookies"). This could be achieved in a number of ways; for example: by clearing the cache, by changing one or both of N and P, or by adding new, synthetic entries to the digest to change its contents.

TODO: discuss how effective the suggested mitigations actually would be.

Additionally, User Agents SHOULD NOT send CACHE\_DIGEST when in "privacy mode."

An HTTP Status Code for Indicating Hints  
draft-ietf-httpbis-early-hints-02

Abstract

This memo introduces an informational HTTP status code that can be used to convey hints that help a client make preparations for processing the final response.

Note to Readers

Discussion of this draft takes place on the HTTP working group mailing list ([ietf-http-wg@w3.org](mailto:ietf-http-wg@w3.org)), which is archived at <https://lists.w3.org/Archives/Public/ietf-http-wg/> .

Working Group information can be found at <https://httpwg.github.io/> ; source code and issues list for this draft can be found at <https://github.com/httpwg/http-extensions/labels/early-hints> .

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on November 17, 2017.

## 1. Introduction

It is common for HTTP responses to contain links to external resources that need to be fetched prior to their use; for example, rendering HTML by a Web browser. Having such links available to the client as early as possible helps to minimize perceived latency.

The "preload" ([Preload]) link relation can be used to convey such links in the Link header field of an HTTP response. However, it is not always possible for an origin server to generate a response header block immediately after receiving a request. For example, the origin server might need to query a database before generating a response, or it might delegate a request to an upstream HTTP server running at a distant location.

The dilemma here is that even though it is preferable for an origin server to send some headers as soon as it receives a request, it cannot do so until the status code and the full headers of the final HTTP response are determined.

HTTP/2 ([RFC7540]) server push can be used as a solution to this issue, but has its own limitations. The responses that can be pushed

using HTTP/2 are limited to those belonging to the same origin. Also, it is impossible to send only the links using server push. Finally, sending HTTP responses for every resource is an inefficient way of using bandwidth, especially when a caching server exists as an intermediary.

This memo defines a status code for sending an informational response ([RFC7231], section 6.2) that contains headers that are likely to be included in the final response. A server can send the informational response containing some of the headers to help the client start making preparations for processing the final response, and then run time-consuming operations to generate the final response. The informational response can also be used by an origin server to trigger HTTP/2 server push at a caching intermediary.

### 1.1. Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

## 2. 103 Early Hints

The 103 (Early Hints) informational status code indicates the client that the server is likely to send a final response with the headers included in the informational response.

A server MUST NOT include Content-Length, Transfer-Encoding, or any hop-by-hop header fields ([RFC7230], section 6.1) in a 103 (Early Hints) response.

A client MAY speculatively evaluate the headers included in a 103 (Early Hints) response while waiting for the final response. For example, a client might recognize a Link header field value containing the relation type "preload" and start fetching the target resource.

However, this MUST NOT affect how the final response is processed; when handling it, the client MUST behave as if it had not seen the informational response. In particular, a client MUST NOT process the headers included in the final response as if they belonged to the informational response, or vice versa.

An intermediary MAY drop the informational response. It MAY send HTTP/2 ([RFC7540]) server pushes using the information found in the 103 (Early Hints) response.

### 3. Security Considerations

Some clients may have issues handling 103 (Early Hints), since informational responses are rarely used in reply to requests not including an Expect header ([RFC7231], section 5.1.1).

In particular, an HTTP/1.1 client that mishandles an informational response as a final response is likely to consider all responses to the succeeding requests sent over the same connection to be part of the final response. Such behavior may constitute a cross-origin information disclosure vulnerability in case the client multiplexes requests to different origins onto a single persistent connection.

Therefore, a server might refrain from sending Early Hints over HTTP/1.1 unless when the client is known to handle informational responses correctly.

HTTP/2 clients are less likely to suffer from incorrect framing since handling of the response headers does not affect how the end of the response body is determined.

### 4. IANA Considerations

The HTTP Status Codes Registry will be updated with the following entry:

- o Code: 103
- o Description: Early Hints
- o Specification: [this document]

### 5. Acknowledgements

Thanks to Tatsuhiro Tsujikawa for coming up with the idea of sending the link headers using an informational response.

### 6. Changes

#### 6.1. Since draft-ietf-httpbis-early-hints-01

- o Editorial changes.

#### 6.2. Since draft-ietf-httpbis-early-hints-00

- o Forbid processing the headers of a 103 response as part of the informational response.

Expect-CT Extension for HTTP  
draft-ietf-httpbis-expect-ct-01

Abstract

This document defines a new HTTP header, named Expect-CT, that allows web host operators to instruct user agents to expect valid Signed Certificate Timestamps (SCTs) to be served on connections to these hosts. When configured in enforcement mode, user agents (UAs) will remember that hosts expect SCTs and will refuse connections that do not conform to the UA's Certificate Transparency policy. When configured in report-only mode, UAs will report the lack of valid SCTs to a URI configured by the host, but will allow the connection. By turning on Expect-CT, web host operators can discover misconfigurations in their Certificate Transparency deployments and ensure that misissued certificates accepted by UAs are discoverable in Certificate Transparency logs.

Note to Readers

1. Introduction

This document defines a new HTTP header that enables UAs to identify web hosts that expect the presence of Signed Certificate Timestamps (SCTs) [I-D.ietf-trans-rfc6962-bis] in future Transport Layer Security (TLS) [RFC5246] connections.

Web hosts that serve the Expect-CT HTTP header are noted by the UA as Known Expect-CT Hosts. The UA evaluates each connection to a Known Expect-CT Host for compliance with the UA's Certificate Transparency (CT) Policy. If the connection violates the CT Policy, the UA sends a report to a URI configured by the Expect-CT Host and/or fails the connection, depending on the configuration that the Expect-CT Host has chosen.

If misconfigured, Expect-CT can cause unwanted connection failures (for example, if a host deploys Expect-CT but then switches to a legitimate certificate that is not logged in Certificate Transparency logs, or if a web host operator believes their certificate to conform to all UAs' CT policies but is mistaken). Web host operators are advised to deploy Expect-CT with caution, by using the reporting feature and gradually increasing the interval where the UA remembers the host as a Known Expect-CT Host. These precautions can help web host operators gain confidence that their Expect-CT deployment is not causing unwanted connection failures.

Expect-CT is a trust-on-first-use (TOFU) mechanism. The first time a UA connects to a host, it lacks the information necessary to require SCTs for the connection. Thus, the UA will not be able to detect and thwart an attack on the UA's first connection to the host. Still, Expect-CT provides value by 1) allowing UAs to detect the use of unlogged certificates after the initial communication, and 2) allowing web hosts to be confident that UAs are only trusting publicly-auditable certificates.

1.1. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

## 1.2. Terminology

Terminology is defined in this section.

**Certificate Transparency Policy** is a policy defined by the UA concerning the number, sources, and delivery mechanisms of Signed Certificate Timestamps that are served on TLS connections. The policy defines the properties of a connection that must be met in order for the UA to consider it CT-qualified.

**Certificate Transparency Qualified** describes a TLS connection for which the UA has determined that a sufficient quantity and quality of Signed Certificate Timestamps have been provided.

**CT-qualified** See **Certificate Transparency Qualified**.

**CT Policy** See **Certificate Transparency Policy**.

**Effective Expect-CT Date** is the time at which a UA observed a valid Expect-CT header for a given host.

**Expect-CT Host** See **HTTP Expect-CT Host**.

**HTTP Expect-CT** is the overall name for the combined UA- and server-side security policy defined by this specification.

**HTTP Expect-CT Host** is a conformant host implementing the HTTP server aspects of HTTP Expect-CT. This means that an Expect-CT Host returns the "Expect-CT" HTTP response header field in its HTTP response messages sent over secure transport.

**Known Expect-CT Host** is an Expect-CT Host that the UA has noted as such. See Section 2.3.3 for particulars.

**UA** is an acronym for "user agent". For the purposes of this specification, a UA is an HTTP client application typically actively manipulated by a user [RFC7230].

**Unknown Expect-CT Host** is an Expect-CT Host that the UA has not noted.

## 2. Server and Client Behavior

### 2.1. Response Header Field Syntax

The "Expect-CT" header field is a new response header defined in this specification. It is used by a server to indicate that UAs should

evaluate connections to the host emitting the header for CT compliance (Section 2.4).

Figure 1 describes the syntax (Augmented Backus-Naur Form) of the header field, using the grammar defined in RFC 5234 [RFC5234] and the rules defined in Section 3.2 of RFC 7230 [RFC7230].

```
Expect-CT           = #expect-ct-directive
expect-ct-directive = directive-name [ "=" directive-value ]
directive-name      = token
directive-value     = token / quoted-string
```

Figure 1: Syntax of the Expect-CT header field

Optional white space ("OWS") is used as defined in Section 3.2.3 of RFC 7230 [RFC7230]. "token" and "quoted-string" are used as defined in Section 3.2.6 of RFC 7230 [RFC7230].

The directives defined in this specification are described below. The overall requirements for directives are:

1. The order of appearance of directives is not significant.
2. A given directive MUST NOT appear more than once in a given header field. Directives are either optional or required, as stipulated in their definitions.
3. Directive names are case insensitive.
4. UAs MUST ignore any header fields containing directives, or other header field value data, that do not conform to the syntax defined in this specification. In particular, UAs must not attempt to fix malformed header fields.
5. If a header field contains any directive(s) the UA does not recognize, the UA MUST ignore those directives.
6. If the Expect-CT header field otherwise satisfies the above requirements (1 through 5), the UA MUST process the directives it recognizes.

#### 2.1.1. The report-uri Directive

The OPTIONAL "report-uri" directive indicates the URI to which the UA SHOULD report Expect-CT failures (Section 2.4). The UA POSTs the reports to the given URI as described in Section 3.

The "report-uri" directive is REQUIRED to have a directive value, for which the syntax is defined in Figure 2.

report-uri-value = absolute-URI

Figure 2: Syntax of the report-uri directive value

"absolute-URI" is defined in Section 4.3 of RFC 3986 [RFC3986].

Hosts may set "report-uri"s that use HTTP or HTTPS. If the scheme in the "report-uri" is one that uses TLS (e.g., HTTPS), UAs MUST check Expect-CT compliance when the host in the "report-uri" is a Known Expect-CT Host; similarly, UAs MUST apply HSTS if the host in the "report-uri" is a Known HSTS Host.

Note that the report-uri need not necessarily be in the same Internet domain or web origin as the host being reported about.

UAs SHOULD make their best effort to report Expect-CT failures to the "report-uri", but they may fail to report in exceptional conditions. For example, if connecting the "report-uri" itself incurs an Expect-CT failure or other certificate validation failure, the UA MUST cancel the connection. Similarly, if Expect-CT Host A sets a "report-uri" referring to Expect-CT Host B, and if B sets a "report-uri" referring to A, and if both hosts fail to comply to the UA's CT Policy, the UA SHOULD detect and break the loop by failing to send reports to and about those hosts.

UAs SHOULD limit the rate at which they send reports. For example, it is unnecessary to send the same report to the same "report-uri" more than once.

#### 2.1.2. The enforce Directive

The OPTIONAL "enforce" directive is a valueless directive that, if present (i.e., it is "asserted"), signals to the UA that compliance to the CT Policy should be enforced (rather than report-only) and that the UA should refuse future connections that violate its CT Policy. When both the "enforce" directive and "report-uri" directive (as defined in Figure 2) are present, the configuration is referred to as an "enforce-and-report" configuration, signalling to the UA both that compliance to the CT Policy should be enforced and that violations should be reported.

### 2.1.3. The max-age Directive

The "max-age" directive specifies the number of seconds after the reception of the Expect-CT header field during which the UA SHOULD regard the host from whom the message was received as a Known Expect-CT Host.

The "max-age" directive is REQUIRED to be present within an "Expect-CT" header field. The "max-age" directive is REQUIRED to have a directive value, for which the syntax (after quoted-string unescaping, if necessary) is defined in Figure 3.

```
max-age-value = delta-seconds
delta-seconds = 1*DIGIT
```

Figure 3: Syntax of the max-age directive value

"delta-seconds" is used as defined in Section 1.2.1 of RFC 7234 [RFC7234].

### 2.1.4. Examples

The following examples demonstrate valid Expect-CT response header fields:

```
Expect-CT: max-age=86400,enforce
```

```
Expect-CT: max-age=86400, enforce, report-uri="https://foo.example/report"
```

```
Expect-CT: max-age=86400,report-uri="https://foo.example/report"
```

Figure 4: Examples of valid Expect-CT response header fields

## 2.2. Server Processing Model

This section describes the processing model that Expect-CT Hosts implement. The model has 2 parts: (1) the processing rules for HTTP request messages received over a secure transport (e.g., authenticated, non-anonymous TLS); and (2) the processing rules for HTTP request messages received over non-secure transports, such as TCP.

### 2.2.1. HTTP-over-Secure-Transport Request Type

When replying to an HTTP request that was conveyed over a secure transport, an Expect-CT Host SHOULD include in its response exactly one Expect-CT header field. The header field MUST satisfy the grammar specified in Section 2.1.

Establishing a given host as an Expect-CT Host, in the context of a given UA, is accomplished as follows:

1. Over the HTTP protocol running over secure transport, by correctly returning (per this specification) at least one valid Expect-CT header field to the UA.
2. Through other mechanisms, such as a client-side preloaded Expect-CT Host list.

#### 2.2.2. HTTP Request Type

Expect-CT Hosts SHOULD NOT include the Expect-CT header field in HTTP responses conveyed over non-secure transport. UAs MUST ignore any Expect-CT header received in an HTTP response conveyed over non-secure transport.

### 2.3. User Agent Processing Model

The UA processing model relies on parsing domain names. Note that internationalized domain names SHALL be canonicalized according to the scheme in Section 10 of [RFC6797].

#### 2.3.1. Expect-CT Header Field Processing

If the UA receives, over a secure transport, an HTTP response that includes an Expect-CT header field conforming to the grammar specified in Section 2.1, the UA MUST evaluate the connection on which the header was received for compliance with the UA's CT Policy, and then process the Expect-CT header field as follows.

If the connection complies with the UA's CT Policy (i.e. the connection is CT-qualified), then the UA MUST either:

- o Note the host as a Known Expect-CT Host if it is not already so noted (see Section 2.3.3), or
- o Update the UA's cached information for the Known Expect-CT Host if the "enforce", "max-age", or "report-uri" header field value directives convey information different from that already maintained by the UA. If the "max-age" directive has a value of 0, the UA MUST remove its cached Expect-CT information if the host was previously noted as a Known Expect-CT Host, and MUST NOT note this host as a Known Expect-CT Host if it is not already noted.

If the connection does not comply with the UA's CT Policy (i.e. is not CT-qualified), then the UA MUST NOT note this host as a Known Expect-CT Host.

If the header field includes a "report-uri" directive, and the connection does not comply with the UA's CT Policy (i.e. the connection is not CT-qualified), and the UA has not already sent an Expect-CT report for this connection, then the UA SHOULD send a report to the specified "report-uri" as specified in Section 3.

The UA MUST ignore any Expect-CT header field not conforming to the grammar specified in Section 2.1.

#### 2.3.2. HTTP-Equiv <meta> Element Attribute

UAs MUST NOT heed "http-equiv="Expect-CT"" attribute settings on "<meta>" elements [W3C.REC-html401-19991224] in received content.

#### 2.3.3. Noting Expect-CT

Upon receipt of the Expect-CT response header field over an error-free TLS connection (including the validation adding in Section 2.4), the UA MUST note the host as a Known Expect-CT Host, storing the host's domain name and its associated Expect-CT directives in non-volatile storage. The domain name and associated Expect-CT directives are collectively known as "Expect-CT metadata".

To note a host as a Known Expect-CT Host, the UA MUST set its Expect-CT metadata given in the most recently received valid Expect-CT header, as specified in Section 2.3.4.

For forward compatibility, the UA MUST ignore any unrecognized Expect-CT header directives, while still processing those directives it does recognize. Section 2.1 specifies the directives "enforce", "max-age", and "report-uri", but future specifications and implementations might use additional directives.

#### 2.3.4. Storage Model

Known Expect-CT Hosts are identified only by domain names, and never IP addresses. If the substring matching the host production from the Request-URI (of the message to which the host responded) syntactically matches the IP-literal or IPv4address productions from Section 3.2.2 of [RFC3986], then the UA MUST NOT note this host as a Known Expect-CT Host.

Otherwise, if the substring does not congruently match an existing Known Expect-CT Host's domain name, per the matching procedure specified in Section 8.2 of [RFC6797], then the UA MUST add this host to the Known Expect-CT Host cache. The UA caches:

- o the Expect-CT Host's domain name,

- o whether the "enforce" directive is present
- o the Effective Expiration Date, which is the Effective Expect-CT Date plus the value of the "max-age" directive. Alternatively, the UA MAY cache enough information to calculate the Effective Expiration Date.
- o the value of the "report-uri" directive, if present.

If any other metadata from optional or future Expect-CT header directives are present in the Expect-CT header, and the UA understands them, the UA MAY note them as well.

UAs MAY set an upper limit on the value of max-age, so that UAs that have noted erroneous Expect-CT hosts (whether by accident or due to attack) have some chance of recovering over time. If the server sets a max-age greater than the UA's upper limit, the UA MAY behave as if the server set the max-age to the UA's upper limit. For example, if the UA caps max-age at 5,184,000 seconds (60 days), and an Expect-CT Host sets a max-age directive of 90 days in its Expect-CT header, the UA MAY behave as if the max-age were effectively 60 days. (One way to achieve this behavior is for the UA to simply store a value of 60 days instead of the 90-day value provided by the Expect-CT host.)

#### 2.4. Evaluating Expect-CT Connections for CT Compliance

When a UA connects to a Known Expect-CT Host using a TLS connection, if the TLS connection has errors, the UA MUST terminate the connection without allowing the user to proceed anyway. (This behavior is the same as that required by [RFC6797].)

If the connection has no errors, then the UA will apply an additional correctness check: compliance with a CT Policy. A UA should evaluate compliance with its CT Policy whenever connecting to a Known Expect-CT Host, as soon as possible. It is acceptable to skip this CT compliance check for some hosts according to local policy. For example, a UA may disable CT compliance checks for hosts whose validated certificate chain terminates at a user-defined trust anchor, rather than a trust anchor built-in to the UA (or underlying platform).

An Expect-CT Host is "expired" if the effective expiration date refers to a date in the past. The UA MUST ignore any expired Expect-CT Hosts in its cache and not treat such hosts as Known Expect-CT hosts.

If a connection to a Known CT Host violates the UA's CT policy (i.e. the connection is not CT-qualified), and if the Known Expect-CT

Host's Expect-CT metadata indicates an "enforce" configuration, the UA MUST treat the CT compliance failure as a non-recoverable error.

If a connection to a Known CT Host violates the UA's CT policy, and if the Known Expect-CT Host's Expect-CT metadata includes a "report-uri", the UA SHOULD send an Expect-CT report to that "report-uri" (Section 3).

A UA that has previously noted a host as a Known Expect-CT Host MUST evaluate CT compliance when setting up the TLS session, before beginning an HTTP conversation over the TLS channel.

If the UA does not evaluate CT compliance, e.g. because the user has elected to disable it, or because a presented certificate chain chains up to a user-defined trust anchor, UAs SHOULD NOT send Expect-CT reports.

### 3. Reporting Expect-CT Failure

When the UA attempts to connect to a Known Expect-CT Host and the connection is not CT-qualified, the UA SHOULD report Expect-CT failures to the "report-uri", if any, in the Known Expect-CT Host's Expect-CT metadata.

When the UA receives an Expect-CT response header field over a connection that is not CT-qualified, if the UA has not already sent an Expect-CT report for this connection, then the UA SHOULD report Expect-CT failures to the configured "report-uri", if any.

#### 3.1. Generating a violation report

To generate a violation report object, the UA constructs a JSON object with the following keys and values:

- o "date-time": the value for this key indicates the time the UA observed the CT compliance failure. The value is a string formatted according to Section 5.6, "Internet Date/Time Format", of [RFC3339].
- o "hostname": the value is the hostname to which the UA made the original request that failed the CT compliance check. The value is provided as a string.
- o "port": the value is the port to which the UA made the original request that failed the CT compliance check. The value is provided as an integer.

- o "effective-expiration-date": the value indicates the Effective Expiration Date (see Section 2.3.4) for the Expect-CT Host that failed the CT compliance check. The value is provided as a string formatted according to Section 5.6, "Internet Date/Time Format", of [RFC3339].
- o "served-certificate-chain": the value is the certificate chain as served by the Expect-CT Host during TLS session setup. The value is provided as an array of strings, which MUST appear in the order that the certificates were served; each string in the array is the Privacy-Enhanced Mail (PEM) representation of each X.509 certificate as described in [RFC7468].
- o "validated-certificate-chain": the value is the certificate chain as constructed by the UA during certificate chain verification. (This may differ from the value of the "served-certificate-chain" key.) The value is provided as an array of strings, which MUST appear in the order matching the chain that the UA validated; each string in the array is the Privacy-Enhanced Mail (PEM) representation of each X.509 certificate as described in [RFC7468].
- o "scts": the value represents the SCTs (if any) that the UA received for the Expect-CT host and their validation statuses. The value is provided as an array of JSON objects. The SCTs may appear in any order. Each JSON object in the array has the following keys:
  - \* The "sct" key, with a value as defined in Section 4.6 of [I-D.ietf-trans-rfc6962-bis].
  - \* The "status" key, with a string value that the UA MUST set to one of the following values: "unknown" (indicating that the UA does not have or does not trust the public key of the log from which the SCT was issued), "valid" (indicating that the UA successfully validated the SCT as described in Section 8.2.3 of [I-D.ietf-trans-rfc6962-bis]), or "invalid" (indicating that the SCT validation failed because of, e.g., a bad signature).
  - \* The "source" key, with a string value that indicates from where the UA obtained the SCT, as defined in Section 6 of [I-D.ietf-trans-rfc6962-bis]. The UA MUST set the value to one of "tls-extension", "ocsp", or "embedded".

### 3.2. Sending a violation report

The UA SHOULD report an Expect-CT failure when a connection to a Known Expect-CT Host does not comply with the UA's CT Policy and the host's Expect-CT metadata contains a "report-uri". Additionally, the UA SHOULD report an Expect-CT failure when it receives an Expect-CT header field which contains the "report-uri" directive over a connection that does not comply with the UA's CT Policy.

The steps to report an Expect-CT failure are as follows.

1. Prepare a JSON object "report object" with the single key "expect-ct-report", whose value is the result of generating a violation report object as described in Section 3.1.
2. Let "report body" be the JSON stringification of "report object".
3. Let "report-uri" be the value of the "report-uri" directive in the Expect-CT header field.
4. Send an HTTP POST request to "report-uri" with a "Content-Type" header field of "application/expect-ct-report+json", and an entity body consisting of "report body".

The UA MAY perform other operations as part of sending the HTTP POST request, for example sending a CORS preflight as part of [FETCH].

### 4. Security Considerations

When UAs support the Expect-CT header, it becomes a potential vector for hostile header attacks against site owners. If a site owner uses a certificate issued by a certificate authority which does not embed SCTs nor serve SCTs via OCSP or TLS extension, a malicious server operator or attacker could temporarily reconfigure the host to comply with the UA's CT policy, and add the Expect-CT header in enforcing mode with a long "max-age". Implementing user agents would note this as an Expect-CT Host (see Section 2.3.3). After having done this, the configuration could then be reverted to not comply with the CT policy, prompting failures. Note this scenario would require the attacker to have substantial control over the infrastructure in question, being able to obtain different certificates, change server software, or act as a man-in-the-middle in connections.

Site operators could themselves only cure this situation by one of: reconfiguring their web server to transmit SCTs using the TLS extension defined in Section 6.5 of [I-D.ietf-trans-rfc6962-bis], obtaining a certificate from an alternative certificate authority which provides SCTs by one of the other methods, or by waiting for

the user agents' persisted notation of this as an Expect-CT host to reach its "max-age". User agents may choose to implement mechanisms for users to cure this situation, as noted in Section 7.

#### 4.1. Maximum max-age

There is a security trade-off in that low maximum values provide a narrow window of protection for users that visit the Known Expect-CT Host only infrequently, while high maximum values might result in a denial of service to a UA in the event of a hostile header attack, or simply an error on the part of the site-owner.

There is probably no ideal maximum for the "max-age" directive. Since Expect-CT is primarily a policy-expansion and investigation technology rather than an end-user protection, a value on the order of 30 days (2,592,000 seconds) may be considered a balance between these competing security concerns.

#### 4.2. Avoiding amplification attacks

Another kind of hostile header attack uses the "report-uri" mechanism on many hosts not currently exposing SCTs as a method to cause a denial-of-service to the host receiving the reports. If some highly-trafficked websites emitted a non-enforcing Expect-CT header with a "report-uri", implementing UAs' reports could flood the reporting host. It is noted in Section 2.1.1 that UAs should limit the rate at which they emit reports, but an attacker may alter the Expect-CT header's fields to induce UAs to submit different reports to different URIs to still cause the same effect.

### 5. Privacy Considerations

Expect-CT can be used to infer what Certificate Transparency policy is in use, by attempting to retrieve specially-configured websites which pass one user agents' policies but not another's. Note that this consideration is true of UAs which enforce CT policies without Expect-CT as well.

Additionally, reports submitted to the "report-uri" could reveal information to a third party about which webpage is being accessed and by which IP address, by using individual "report-uri" values for individually-tracked pages. This information could be leaked even if client-side scripting were disabled.

Implementations must store state about Known Expect-CT Hosts, and hence which domains the UA has contacted.

Violation reports, as noted in Section 3, contain information about the certificate chain that has violated the CT policy. In some cases, such as organization-wide compromise of the end-to-end security of TLS, this may include information about the interception tools and design used by the organization that the organization would otherwise prefer not be disclosed.

Because Expect-CT causes remotely-detectable behavior, it's advisable that UAs offer a way for privacy-sensitive users to clear currently noted Expect-CT hosts, and allow users to query the current state of Known Expect-CT Hosts.

## 6. IANA Considerations

TBD

## 7. Usability Considerations

When the UA detects a Known Expect-CT Host in violation of the UA's CT Policy, users will experience denials of service. It is advisable for UAs to explain the reason why.

## 8. Authoring Considerations

### 8.1. HTTP Header

Expect-CT could be specified as a TLS extension or X.509 certificate extension instead of an HTTP response header. Using an HTTP header as the mechanism for Expect-CT introduces a layering mismatch: for example, the software that terminates TLS and validates Certificate Transparency information might know nothing about HTTP. Nevertheless, an HTTP header was chosen primarily for ease of deployment. In practice, deploying new certificate extensions requires certificate authorities to support them, and new TLS extensions require server software updates, including possibly to servers outside of the site owner's direct control (such as in the case of a third-party CDN). Ease of deployment is a high priority for Expect-CT because it is intended as a temporary transition mechanism for user agents that are transitioning to universal Certificate Transparency requirements.

## 9. Changes

### 9.1. Since -00

- o Editorial changes

- o Change Content-Type header of reports to 'application/expect-ct-report+json'
- o Update header field syntax to match convention (issue #327)
- o Reference RFC 6962-bis instead of RFC 6962

HTTP Header Common Structure  
draft-ietf-httpbis-header-structure-01

Abstract

An abstract data model for HTTP headers, "Common Structure", and a HTTP/1 serialization of it, generalized from current HTTP headers.

Note to Readers

Discussion of this draft takes place on the HTTP working group mailing list ([ietf-http-wg@w3.org](mailto:ietf-http-wg@w3.org)), which is archived at <https://lists.w3.org/Archives/Public/ietf-http-wg/> .

Working Group information can be found at <http://httpwg.github.io/> ; source code and issues list for this draft can be found at <https://github.com/httpwg/http-extensions/labels/header-structure> .

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on October 26, 2017.

## 1. Introduction

The HTTP protocol does not impose any structure or datamodel on the information in HTTP headers, the HTTP/1 serialization is the datamodel: An ASCII string without control characters.

HTTP header definitions specify how the string must be formatted and while families of similar headers exist, it still requires an uncomfortable large number of bespoke parser and validation routines to process HTTP traffic correctly.

In order to improve performance HTTP/2 and HPACK uses naive text-compression, which incidentally decoupled the on-the-wire serialization from the data model.

During the development of HPACK it became evident that significantly bigger gains were available if semantic compression could be used, most notably with timestamps. However, the lack of a common data structure for HTTP headers would make semantic compression one long list of special cases.

Parallel to this, various proposals for how to fulfill data-transportation needs, and to a lesser degree to impose some kind of order on HTTP headers, at least going forward, were floated.

All of these proposals, JSON, CBOR etc. run into the same basic problem: Their serialization is incompatible with RFC 7230's [RFC7230] ABNF definition of 'field-value'.

For binary formats, such as CBOR, a wholesale base64/85 reserialization would be needed, with negative results for both debugability and bandwidth.

For textual formats, such as JSON, the format must first be neutered to not violate field-value's ABNF, and then workarounds added to reintroduce the features just lost, for instance UNICODE strings.

The post-surgery format is no longer JSON, and it experience indicates that almost-but-not-quite compatibility is worse than no compatibility.

This proposal starts from the other end, and builds and generalizes a data structure definition from existing HTTP headers, which means that HTTP/1 serialization and 'field-value' compatibility is built in.

If all future HTTP headers are defined to fit into this Common Structure we have at least halted the proliferation of bespoke parsers and started to pave the road for semantic compression serializations of HTTP traffic.

### 1.1. Terminology

In this document, the key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" are to be interpreted as described in BCP 14, RFC 2119 [RFC2119].

## 2. Definition of HTTP Header Common Structure

The data model of Common Structure is an ordered sequence of named dictionaries. Please see Appendix A for how this model was derived.

The definition of the data model is on purpose abstract, uncoupled from any protocol serialization or programming environment representation, it is meant as the foundation on which all such manifestations of the model can be built.

Common Structure in ABNF (Slightly bastardized relative to RFC5234 [RFC5234]):

```
import token from RFC7230
import DIGIT from RFC5234

common-structure = 1* ( identifier dictionary )

dictionary = * ( identifier [ value ] )

value = identifier /
        integer /
        number /
        ascii-string /
        unicode-string /
        blob /
        timestamp /
        common-structure
```

Recursion is included as a way to support deep and more general data structures, but its use is highly discouraged and where it is

used the depth of recursion SHALL always be explicitly limited in the specifications of the HTTP headers which allow it.

```
identifier = token [ "/" token ]
```

```
integer = ["-"] 1*19 DIGIT
```

Integers SHALL be in the range +/- 2<sup>63</sup>-1 (= +/- 9223372036854775807)

```
number = ["-"] DIGIT '.' 1*14DIGIT /
         ["-"] 2DIGIT '.' 1*13DIGIT /
         ["-"] 3DIGIT '.' 1*12DIGIT /
         ... /
         ["-"] 12DIGIT '.' 1*3DIGIT /
         ["-"] 13DIGIT '.' 1*2DIGIT /
         ["-"] 14DIGIT '.' 1DIGIT
```

The limit of 15 significant digits is chosen so that numbers can be correctly represented by IEEE754 64 bit binary floating point.

```
ascii-string = * %x20-7e
```

This is intended to be an efficient, "safe" and uncomplicated string type, for uses where the string content is culturally neutral or where it will not be user visible.

```
unicode-string = * UNICODE
```

```
UNICODE = <U+0000-U+D7FF / U+E000-U+10FFFF>
# UNICODE nicked from draft-seantek-unicode-in-abnf-02
```

Unicode-strings are unrestricted because there is no sane and/or culturally neutral way to subset or otherwise make unicode "safe", and Unicode is still evolving new and interesting code points.

Users of unicode-string SHALL be prepared for the full gammut of glyph-gymnastics in order to avoid U+1F4A9 U+08 U+1F574.

```
blob = * %0x00-ff
```

Blobs are intended primarily for cryptographic data, but can be used for any otherwise unsatisfied needs.

```
timestamp = number
```

A timestamp counts seconds since the UNIX time\_t epoch, including the "invisible leap-seconds" misfeature.

### 3. HTTP/1 Serialization of HTTP Header Common Structure

In ABNF:

```
import OWS from RFC7230
import HEXDIG, DQUOTE from RFC5234
import EmbeddedUnicodeChar from RFC5137

hl-common-structure-header =
    hl-common-structure-legacy-header /
    hl-common-structure-self-identifying-header

hl-common-structure-legacy-header =
    field-name ":" OWS hl-common-structure
```

Only white-listed legacy headers (see Section 8) can use this format.

```

h1-common-structure-self-identifying-header:
    field-name ":" OWS ">" h1-common-structure "<"

h1-common-structure = h1-element * ("," h1-element)

h1-element = identifier * (";" identifier ["=" h1-value])

h1-value = identifier /
    integer /
    number /
    h1-ascii-string /
    h1-unicode-string /
    h1-blob /
    h1-timestamp /
    ">" h1-common-structure "<"

h1-ascii-string = DQUOTE *(
    ( "\" DQUOTE ) /
    ( "\" "\"" ) /
    0x20-21 /
    0x23-5B /
    0x5D-7E
    ) DQUOTE

h1-unicode-string = DQUOTE *(
    ( "\" DQUOTE )
    ( "\" "\"" ) /
    EmbeddedUnicodeChar /
    0x20-21 /
    0x23-5B /
    0x5D-7E /
    ) DQUOTE

```

The dim prospects of ever getting a majority of HTTP1 paths 8-bit clean makes UTF-8 unviable as H1 serialization. Given that very little of the information in HTTP headers is presented to users in the first place, improving H1 and HPACK efficiency by inventing a more efficient RFC5137 compliant escape-sequences seems unwarranted.

```

h1-blob = ":" base64 ":"
# XXX: where to import base64 from ?

```

```

h1-timestamp = number

```

XXX: Allow OWS in parsers, but not in generators ?

In programming environments which do not define a native representation or serialization of Common Structure, the HTTP/1 serialization should be used.

#### 4. When to use Common Structure Parser

All future standardized and all private HTTP headers using Common Structure should self identify as such. In the HTTP/1 serialization by making the first character ">" and the last "<". (These two characters are deliberately "the wrong way" to not clash with existing usages.)

Legacy HTTP headers which fit into Common Structure, are marked as such in the IANA Message Header Registry (see Section 8), and a snapshot of the registry can be used to trigger parsing according to Common Structure of these headers.

#### 5. Desired Normative Effects

All new HTTP headers SHOULD use the Common Structure if at all possible.

#### 6. Open/Outstanding issues to resolve

##### 6.1. Single/Multiple Headers

Should we allow splitting common structure data over multiple headers ?

Pro:

Avoids size restrictions, easier on-the-fly editing

Contra:

Cannot act on any such header until all headers have been received.

We must define where headers can be split (between identifier and dictionary ?, in the middle of dictionaries ?)

Most on-the-fly editing is hackish at best.

#### 7. Future Work

### 7.1. Redefining existing headers for better performance

The HTTP/1 serializations self-identification mechanism makes it possible to extend the definition of existing Appendix A.5 headers into Common Structure.

For instance one could imagine:

```
Date: >1475061449.201<
```

Which would be faster to parse and validate than the current definition of the Date header and more precise too.

Some kind of signal/negotiation mechanism would be required to make this work in practice.

### 7.2. Define a validation dictionary

A machine-readable specification of the legal contents of HTTP headers would go a long way to improve efficiency and security in HTTP implementations.

## 8. IANA Considerations

The IANA Message Header Registry will be extended with an additional field named "Common Structure" which can have the values "True", "False" or "Unknown".

The RFC723x headers listed in Appendix A.4 will get the value "True" in the new field.

The RFC723x headers listed in Appendix A.5 will get the value "False" in the new field.

All other existing entries in the registry will be set to "Unknown" until and if the owner of the entry requests otherwise.

## 9. Security Considerations

Unique dictionary keys are required to reduce the risk of smuggling attacks.

#### Appendix A. Do HTTP headers have any common structure ?

Several proposals have been floated in recent years to use some preexisting structured data serialization or other for HTTP headers, to impose some sanity.

None of these proposals have gained traction and no obvious candidate data serializations have been left unexamined.

This effort tries to tackle the question from the other side, by asking if there is a common structure in existing HTTP headers we can generalize for this purpose.

##### A.1. Survey of HTTP header structure

The RFC723x family of HTTP/1 standards control 49 entries in the IANA Message Header Registry, and they share two common motifs.

The majority of RFC723x HTTP headers are lists. A few of them are ordered, ('Content-Encoding'), some are unordered ('Connection') and some are ordered by 'q=%f' weight parameters ('Accept')

In most cases, the list elements are some kind of identifier, usually derived from ABNF 'token' as defined by [RFC7230].

A subgroup of headers, mostly related to MIME, uses what one could call a 'qualified token'::

```
qualified-token = token-or-asterix [ "/" token-or-asterix ]
```

The second motif is parameterized list elements. The best known is the "q=0.5" weight parameter, but other parameters exist as well.

Generalizing from these motifs, our candidate "Common Structure" data model becomes an ordered list of named dictionaries.

In pidgin ABNF, ignoring white-space for the sake of clarity, the HTTP/1.1 serialization of Common Structure is something like:

token-or-asterix = token from RFC7230, but also allowing "\*"

qualified-token = token-or-asterix [ "/" token-or-asterix ]

field-name, see RFC7230

Common-Structure-Header = field-name ":" 1#named-dictionary

named-dictionary = qualified-token [ \*("; " param) ]

param = token [ "=" value ]

value = we'll get back to this in a moment.

Nineteen out of the RFC723x's 48 headers, almost 40%, can already be parsed using this definition, and none the rest have requirements which could not be met by this data model. See Appendix A.4 and Appendix A.5 for the full survey details.

## A.2. Survey of values in HTTP headers

Surveying the datatypes of HTTP headers, standardized as well as private, the following picture emerges:

### A.2.1. Numbers

Integer and floating point are both used. Range and precision is mostly unspecified in controlling documents.

Scientific notation (9.192631770e9) does not seem to be used anywhere.

The ranges used seem to be minus several thousand to plus a couple of billions, the high end almost exclusively being POSIX time\_t timestamps.

### A.2.2. Timestamps

RFC723x text format, but POSIX time\_t represented as integer or floating point is not uncommon. ISO8601 have also been spotted.

### A.2.3. Strings

The vast majority are pure ASCII strings, with either no escapes, %xx URL-like escapes or C-style back-slash escapes, possibly with the addition of \uxxxx UNICODE escapes.

Where non-ASCII character sets are used, they are almost always implicit, rather than explicit. UTF8 and ISO-8859-1 seem to be most common.

#### A.2.4. Binary blobs

Often used for cryptographic data. Usually in base64 encoding, sometimes "-"-quoted more often not. base85 encoding is also seen, usually quoted.

#### A.2.5. Identifiers

Seems to almost always fit in the RFC723x 'token' definition.

### A.3. Is this actually a useful thing to generalize ?

The number one wishlist item seems to be UNICODE strings, with a big side order of not having to write a new parser routine every time somebody comes up with a new header.

Having a common parser would indeed be a good thing, and having an underlying data model which makes it possible define a compressed serialization, rather than rely on serialization to text followed by text compression (ie: HPACK) seems like a good idea too.

However, when using a datamodel and a parser general enough to transport useful data, it will have to be followed by a validation step, which checks that the data also makes sense.

Today validation, such as it is, is often done by the bespoke parsers.

This then is probably where the next big potential for improvement lies:

Ideally a machine readable "data dictionary" which makes it possibly to copy that text out of RFCs, run it through a code generator which spits out validation code which operates on the output of the common parser.

But history has been particularly unkind to that idea.

Most attempts studied as part of this effort, have sunk under complexity caused by reaching for generality, but where scope has been wisely limited, it seems to be possible.

So file that idea under "future work".

## A.4. RFC723x headers with "common structure"

- o Accept [RFC7231], Section 5.3.2
- o Accept-Charset [RFC7231], Section 5.3.3
- o Accept-Encoding [RFC7231], Section 5.3.4, [RFC7694], Section 3
- o Accept-Language [RFC7231], Section 5.3.5
- o Age [RFC7234], Section 5.1
- o Allow [RFC7231], Section 7.4.1
- o Connection [RFC7230], Section 6.1
- o Content-Encoding [RFC7231], Section 3.1.2.2
- o Content-Language [RFC7231], Section 3.1.3.2
- o Content-Length [RFC7230], Section 3.3.2
- o Content-Type [RFC7231], Section 3.1.1.5
- o Expect [RFC7231], Section 5.1.1
- o Max-Forwards [RFC7231], Section 5.1.2
- o MIME-Version [RFC7231], Appendix A.1
- o TE [RFC7230], Section 4.3
- o Trailer [RFC7230], Section 4.4
- o Transfer-Encoding [RFC7230], Section 3.3.1
- o Upgrade [RFC7230], Section 6.7
- o Vary [RFC7231], Section 7.1.4

## A.5. RFC723x headers with "uncommon structure"

1 of the RFC723x headers is only reserved, and therefore have no structure at all:

- o Close [RFC7230], Section 8.1

5 of the RFC723x headers are HTTP dates:

- o Date [RFC7231], Section 7.1.1.2
- o Expires [RFC7234], Section 5.3
- o If-Modified-Since [RFC7232], Section 3.3
- o If-Unmodified-Since [RFC7232], Section 3.4
- o Last-Modified [RFC7232], Section 2.2

24 of the RFC723x headers use bespoke formats which only a single or in rare cases two headers share:

- o Accept-Ranges [RFC7233], Section 2.3
  - \* bytes-unit / other-range-unit
- o Authorization [RFC7235], Section 4.2
- o Proxy-Authorization [RFC7235], Section 4.4
  - \* credentials
- o Cache-Control [RFC7234], Section 5.2
  - \* 1#cache-directive
- o Content-Location [RFC7231], Section 3.1.4.2
  - \* absolute-URI / partial-URI
- o Content-Range [RFC7233], Section 4.2
  - \* byte-content-range / other-content-range
- o ETag [RFC7232], Section 2.3
  - \* entity-tag
- o Forwarded [RFC7239]
  - \* 1#forwarded-element
- o From [RFC7231], Section 5.5.1
  - \* mailbox
- o If-Match [RFC7232], Section 3.1

- o If-None-Match [RFC7232], Section 3.2
  - \* "\*" / 1#entity-tag
- o If-Range [RFC7233], Section 3.2
  - \* entity-tag / HTTP-date
- o Host [RFC7230], Section 5.4
  - \* uri-host [ ":" port ]
- o Location [RFC7231], Section 7.1.2
  - \* URI-reference
- o Pragma [RFC7234], Section 5.4
  - \* 1#pragma-directive
- o Range [RFC7233], Section 3.1
  - \* byte-ranges-specifier / other-ranges-specifier
- o Referer [RFC7231], Section 5.5.2
  - \* absolute-URI / partial-URI
- o Retry-After [RFC7231], Section 7.1.3
  - \* HTTP-date / delay-seconds
- o Server [RFC7231], Section 7.4.2
- o User-Agent [RFC7231], Section 5.5.3
  - \* product \*( RWS ( product / comment ) )
- o Via [RFC7230], Section 5.7.1
  - \* 1#( received-protocol RWS received-by [ RWS comment ] )
- o Warning [RFC7234], Section 5.5
  - \* 1#warning-value
- o Proxy-Authenticate [RFC7235], Section 4.3

- o WWW-Authenticate [RFC7235], Section 4.1
  - \* l#challenge

## Appendix B. Changes

### B.1. Since draft-ietf-httpbis-header-structure-00

Added signed 64bit integer type.

Drop UTF8, and settle on BCP137 [RFC5137>::EmbeddedUnicodeChar for hl-unicode-string.

Change hl\_blob delimiter to ":" since "'" is valid t\_char

HTTP Immutable Responses  
draft-ietf-httpbis-immutable-02

Abstract

The immutable HTTP response Cache-Control extension allows servers to identify resources that will not be updated during their freshness lifetime. This assures that a client never needs to revalidate a cached fresh resource to be certain it has not been modified.

Note to Readers

Discussion of this draft takes place on the HTTP working group mailing list ([ietf-http-wg@w3.org](mailto:ietf-http-wg@w3.org)), which is archived at <https://lists.w3.org/Archives/Public/ietf-http-wg/> .

Working Group information can be found at <http://httpwg.github.io/> ; source code and issues list for this draft can be found at <https://github.com/httpwg/http-extensions/labels/immutable> .

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on November 1, 2017.

## 1. Introduction

HTTP's freshness lifetime mechanism [RFC7234] allows a client to safely reuse a stored response to satisfy future requests for a specified period of time. However, it is still possible that the resource will be modified during that period.

For instance, a front page newspaper photo with a freshness lifetime of one hour would mean that no user would see a cached photo more than one hour old. However, the photo could be updated at any time resulting in different users seeing different photos depending on the contents of their caches for up to one hour. This is compliant with the caching mechanism defined in [RFC7234].

Users that need to confirm there have been no updates to their cached responses typically use the reload (or refresh) mechanism in their user agents. This in turn generates a conditional request [RFC7232] and either a new representation or, if unmodified, a 304 (Not Modified) response [RFC7232] is returned. A user agent that understands HTML and fetches its dependent sub-resources might issue hundreds of conditional requests to refresh all portions of a common page [REQPERPAGE].

However some content providers never create more than one variant of a sub-resource, because they use "versioned" URLs. When these resources need an update they are simply published under a new URL, typically embedding an identifier unique to that version of the resource in the path, and references to the sub-resource are updated with the new path information.

For example, "<https://www.example.com/101016/main.css>" might be updated and republished as "<https://www.example.com/102026/main.css>", with any links that reference it being changed at the same time. This design pattern allows a very large freshness lifetime to be used for the sub-resource without guessing when it will be updated in the future.

Unfortunately, the user agent does not know when this versioned URL design pattern is used. As a result, user-driven refreshes still translate into wasted conditional requests for each sub-resource as each will return 304 responses.

The "immutable" HTTP response Cache-Control extension allows servers to identify responses that will not be updated during their freshness lifetimes.

This effectively informs clients that any conditional request for that response can be safely skipped without worrying that it has been updated.

## 2. The immutable Cache-Control extension

When present in an HTTP response, the "immutable" Cache-Control extension indicates that the origin server will not update the representation of that resource during the freshness lifetime of the response.

Clients SHOULD NOT issue a conditional request during the response's freshness lifetime (e.g. upon a reload) unless explicitly overridden by the user (e.g. a force reload).

The immutable extension only applies during the freshness lifetime of the stored response. Stale responses SHOULD be revalidated as they normally would be in the absence of immutable.

The immutable extension takes no arguments. If any arguments are present, they have no meaning, and MUST be ignored. Multiple instances of the immutable extension are equivalent to one instance. The presence of an immutable Cache-Control extension in a request has no effect.

### 2.1. About Intermediaries

An immutable response has the same semantic meaning when received by proxy clients as it does when received by User-Agent based clients. Therefore proxies SHOULD skip conditionally revalidating fresh responses containing the immutable extension unless there is a signal from the client that a validation is necessary (e.g. a no-cache Cache-Control request directive).

A proxy that uses immutable to bypass a conditional revalidation may choose whether to reply with a 304 or 200 to its requesting client based on the request headers the proxy received.

## 2.2. Example

Cache-Control: max-age=31536000, immutable

## 3. Security Considerations

The immutable mechanism acts as form of soft pinning and, as with all pinning mechanisms, creates a vector for amplification of cache corruption incidents. These incidents include cache poisoning attacks. Three mechanisms are suggested for mitigation of this risk:

- o Clients SHOULD ignore immutable from resources that are not part of an authenticated context such as HTTPS. Authenticated resources are less vulnerable to cache poisoning.
- o User-Agents often provide two different refresh mechanisms: reload and some form of force-reload. The latter is used to rectify interrupted loads and other corruption. These reloads, typically indicated through no-cache request attributes, SHOULD ignore immutable as well.
- o Clients SHOULD ignore immutable for resources that do not provide a strong indication that the stored response size is the correct response size such as responses delimited by connection close.

## 4. IANA Considerations

[RFC7234] sections 7.1 and 7.1.2 require registration of the immutable extension in the "Hypertext Transfer Protocol (HTTP) Cache Directive Registry" with IETF Review.

- o Cache-Directive: immutable
- o Pointer to specification text: [this document]

## 5. Acknowledgments

Thank you to Ben Maurer for partnership in developing and testing this idea. Thank you to Amos Jeffries for help with proxy interactions and to Mark Nottingham for help with the documentation.

The ORIGIN HTTP/2 Frame  
draft-ietf-httpbis-origin-frame-03

Abstract

This document specifies the ORIGIN frame for HTTP/2, to indicate what origins are available on a given connection.

Note to Readers

Discussion of this draft takes place on the HTTP working group mailing list ([ietf-http-wg@w3.org](mailto:ietf-http-wg@w3.org)), which is archived at <https://lists.w3.org/Archives/Public/ietf-http-wg/> .

Working Group information can be found at <http://httpwg.github.io/> ; source code and issues list for this draft can be found at <https://github.com/httpwg/http-extensions/labels/origin-frame> .

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on October 22, 2017.

## 1. Introduction

HTTP/2 [RFC7540] allows clients to coalesce different origins [RFC6454] onto the same connection when certain conditions are met. However, in certain cases, a connection is is not usable for a coalesced origin, so the 421 (Misdirected Request) status code ([RFC7540], Section 9.1.2) was defined.

Using a status code in this manner allows clients to recover from misdirected requests, but at the penalty of adding latency. To address that, this specification defines a new HTTP/2 frame type, "ORIGIN", to allow servers to indicate what origins a connection is usable for.

Additionally, experience has shown that HTTP/2's requirement to establish server authority using both DNS and the server's certificate is onerous. This specification relaxes the requirement to check DNS when the ORIGIN frame is in use. Doing so has additional benefits, such as removing the latency associated with some DNS lookups, and improving DNS privacy.

### 1.1. Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

## 2. The ORIGIN HTTP/2 Frame

The ORIGIN HTTP/2 frame ([RFC7540], Section 4) allows a server to indicate what origin(s) [RFC6454] the server would like the client to consider as members of the Origin Set (Section 2.3) for the connection it occurs within.

### 2.1. Syntax

The ORIGIN frame type is 0xc (decimal 12).

```
+-----+-----+
|          Origin-Len (16)          | ASCII-Origin? (*)          ...
+-----+-----+
```

The ORIGIN frame's payload contains the following fields, sets of which may be repeated within the frame to indicate multiple origins:

**Origin-Len:** An unsigned, 16-bit integer indicating the length, in octets, of the ASCII-Origin field.

**Origin:** An optional sequence of characters containing the ASCII serialization of an origin ([RFC6454], Section 6.2) that the sender believes this connection is or could be authoritative for.

The ORIGIN frame does not define any flags. However, future updates to this specification MAY define flags. See Section 2.2.

### 2.2. Processing ORIGIN Frames

The ORIGIN frame is a non-critical extension to HTTP/2. Endpoints that do not support this frame can safely ignore it upon receipt.

When received by an implementing client, it is used to initialise and manipulate the Origin Set (see Section 2.3), thereby changing how the client establishes authority for origin servers (see Section 2.4).

The origin frame MUST be sent on stream 0; an ORIGIN frame on any other stream is invalid and MUST be ignored.

Likewise, the ORIGIN frame is only valid on connections with the "h2" protocol identifier, or when specifically nominated by the protocol's

definition; it MUST be ignored when received on a connection with the "h2c" protocol identifier.

This specification does not define any flags for the ORIGIN frame, but future updates might use them to change its semantics. The first four flags (0x1, 0x2, 0x4 and 0x8) are reserved for backwards-incompatible changes, and therefore when any of them are set, the ORIGIN frame containing them MUST be ignored by clients conforming to this specification, unless the flag's semantics are understood. The remaining flags are reserved for backwards-compatible changes, and do not affect processing by clients conformant to this specification.

The ORIGIN frame describes a property of the connection, and therefore is processed hop-by-hop. An intermediary MUST NOT forward ORIGIN frames. Clients configured to use a proxy MUST ignore any ORIGIN frames received from it.

Each ASCII-Origin field in the frame's payload MUST be parsed as an ASCII serialisation of an origin ([RFC6454], Section 6.2). If parsing fails, the field MUST be ignored.

See Appendix A for an illustrative algorithm for processing ORIGIN frames.

### 2.3. The Origin Set

The set of origins (as per [RFC6454]) that a given connection might be used for is known in this specification as the Origin Set.

By default, a connection's Origin Set is uninitialised. When an ORIGIN frame is first received and successfully processed by a client, the connection's Origin Set is defined to contain a single origin, composed from:

- o Scheme: "https"
- o Host: the value sent in Server Name Indication ([RFC6066] Section 3), converted to lower case
- o Port: the remote port of the connection (i.e., the server's port)

The contents of that ORIGIN frame (and subsequent ones) allows the server to incrementally add new origins to the Origin Set, as described in Section 2.2.

The Origin Set is also affected by the 421 (Misdirected Request) response status code, defined in [RFC7540] Section 9.1.2. Upon receipt of a response with this status code, implementing clients

MUST create the ASCII serialisation of the corresponding request's origin (as per [RFC6454], Section 6.2) and remove it from the connection's Origin Set, if present.

#### 2.4. Authority, Push and Coalescing with ORIGIN

[RFC7540], Section 10.1 uses both DNS and the presented TLS certificate to establish the origin server(s) that a connection is authoritative for, just as HTTP/1.1 does in [RFC7230]. Furthermore, [RFC7540] Section 9.1.1 explicitly allows a connection to be used for more than one origin server, if it is authoritative. This affects what requests can be sent on the connection, both in HEADERS frame by the client and as PUSH\_PROMISE frames from the server.

Once an Origin Set has been initialised for a connection, clients that implement this specification change these behaviors in the following ways:

- o Clients MUST NOT consult DNS to establish the connection's authority for new requests. The TLS certificate MUST still be used to do so, as described in [RFC7540] Section 9.1.1.
- o Clients sending a new request SHOULD use an existing connection if the request's origin is in that connection's Origin Set, unless there are operational reasons for creating a new connection.
- o Clients MUST use the Origin Set to determine whether a received PUSH\_PROMISE is authoritative, as described in [RFC7540], Section 8.2.2.

Note that clients are still required to perform checks on the certificate presented by the server for each origin that a connection is used for; see [RFC7540] Section 9.1.1 for more information. This includes verifying that the host matches a "dNSName" value from the certificate "subjectAltName" field (using the wildcard rules defined in [RFC2818]; see also [RFC5280] Section 4.2.1.6).

Because ORIGIN can change the set of origins a connection is used for over time, it is possible that a client might have more than one viable connection to an origin open at any time. When this occurs, clients SHOULD not emit new requests on any connection whose Origin Set is a subset of another connection's Origin Set, and SHOULD close it once all outstanding requests are satisfied.

### 3. IANA Considerations

This specification adds an entry to the "HTTP/2 Frame Type" registry.

- o Frame Type: ORIGIN
- o Code: 0xc
- o Specification: [this document]

### 4. Security Considerations

Clients that blindly trust the ORIGIN frame's contents will be vulnerable to a large number of attacks. See Section 2.4 for mitigations.

Relaxing the requirement to consult DNS when determining authority for an origin means that an attacker who possesses a valid certificate no longer needs to be on-path to redirect traffic to them; instead of modifying DNS, they need only convince the user to visit another Web site, in order to coalesce connections to the target onto their existing connection.

## Appendix A. Non-Normative Processing Algorithm

The following algorithm illustrates how a client could handle received ORIGIN frames:

1. If the client is configured to use a proxy for the connection, ignore the frame and stop processing.
2. If the connection is not identified with the "h2" protocol identifier or another protocol that has explicitly opted into this specification, ignore the frame and stop processing.
3. If the frame occurs upon any stream except stream 0, ignore the frame and stop processing.
4. If any of the flags 0x1, 0x2, 0x4 or 0x8 are set, ignore the frame and stop processing.
5. If no previous ORIGIN frame on the connection has reached this step, initialise the Origin Set as per Section 2.3.
6. For each Origin field "origin\_raw" in the frame payload:

1. Parse "origin\_raw" as an ASCII serialization of an origin ([RFC6454], Section 6.2) and let the result be "parsed\_origin". If parsing fails, skip to the next "origin\_raw".
2. Add "parsed\_origin" to the Origin Set.

## Appendix B. Operational Considerations for Servers

The ORIGIN frame allows a server to indicate for which origins a given connection ought be used.

For example, it can be used to inform the client that the connection is to only be used for the SNI-based origin, by sending an empty ORIGIN frame. Or, a larger number of origins can be indicated by including a payload.

Generally, this information is most useful to send before sending any part of a response that might initiate a new connection; for example, "Link" headers [RFC5988] in a response HEADERS, or links in the response body.

Therefore, the ORIGIN frame ought be sent as soon as possible on a connection, ideally before any HEADERS or PUSH\_PROMISE frames.

However, if it's desirable to associate a large number of origins with a connection, doing so might introduce end-user perceived latency, due to their size. As a result, it might be necessary to select a "core" set of origins to send initially, expanding the set of origins the connection is used for with subsequent ORIGIN frames later (e.g., when the connection is idle).

That said, senders are encouraged to include as many origins as practical within a single ORIGIN frame; clients need to make decisions about creating connections on the fly, and if the origin set is split across many frames, their behaviour might be suboptimal.

Senders take note that, as per [RFC6454] Section 4, the values in an ORIGIN header need to be case-normalised before serialisation.

Finally, servers that host alternative services [RFC7838] will need to explicitly advertise their origins when sending ORIGIN, because the default contents of the Origin Set (as per Section 2.3) do not contain any Alternative Services' origins, even if they have been used previously on the connection.

HTTP Random Access and Live Content  
draft-ietf-httpbis-rand-access-live-00

Abstract

To accommodate byte range requests for content that has data appended over time, this document defines semantics that allow a HTTP client and server to perform byte-range GET and HEAD requests that start at an arbitrary byte offset within the representation and ends at an indeterminate offset.

Editorial Note (To be removed by RFC Editor before publication)

Discussion of this draft takes place on the HTTPBIS working group mailing list ([ietf-http-wg@w3.org](mailto:ietf-http-wg@w3.org)), which is archived at <https://lists.w3.org/Archives/Public/ietf-http-wg/>.

Working Group information can be found at <http://httpwg.github.io/>; source code and issues list for this draft can be found at <https://github.com/httpwg/http-extensions/labels/rand-access-live>.

Status of This Memo

1. Introduction

Some Hypertext Transfer Protocol (HTTP) Clients use byte-range requests (Range requests using the "bytes" Range Unit) to transfer select portions of large representations. And in some cases large representations require content to be continuously or periodically appended - such as representations consisting of live audio or video sources, blockchain databases, and log files. Clients cannot access the appended/live content using a Range request with the bytes range unit using the currently defined byte-range semantics without accepting performance or behavior sacrifices which are not acceptable for many applications.

For instance, HTTP Clients have the ability to access appended content by simply transferring the entire accessible portion of the representation from the beginning and continuing to read the appended content as it's made available. Obviously, this is highly inefficient for cases where the representation is large and only a portion of the randomly accessible content is needed by the Client. And when bandwidth is limited, the client may never "catch up" with the appending content.

Clients can also attempt to access appended content by sending periodic bytes Range requests using the last-known end byte position (polling). Performing low-frequency periodic bytes Range requests in this fashion (polling) introduces latency since the Client will necessarily be somewhat behind the aggregated content - mimicking the behavior (and latency) of segmented content representations such as HLS or MPEG-DASH. And performing these Range requests at higher frequency incurs more processing overhead and HTTP traffic as the periodic requests will often return no content - since content is usually aggregated in groups of bytes (e.g. a video frame, audio sample, block, or log entry).

To accommodate byte-range requests on large representations which have data appended over time efficiently and with low latency, this recommendation defines semantics whereby the HTTP Client performs byte-range requests using a combination of open-ended byte-range HEAD requests and GET requests using "Large Value" last-byte-pos values.

### 1.1. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

## 2. Performing Range requests on Random-Access Aggregating ("live") Content

There are two critical operations for accessing randomly accessing live/aggregating representations:

- Establishing the randomly accessible range of the representation, and

- Performing range requests that continue beyond the randomly accessible range.

## 2.1. Establishing the Randomly Accessible Byte Range

Establishing if a representation is continuously aggregating ("live") and determining the randomly accessible byte range can both be determined using the existing definition for an open-ended byte-range request. Specifically, [RFC7233] defines a byte-range request of the form:

```
byte-range-spec = first-byte-pos "-" [ last-byte-pos ]
```

which allows a Client to send a request with a first-byte-pos and leave last-byte-pos absent. A Server that receives a satisfiable byte-range request (with first-byte-pos smaller than the current representation length) must respond with a 206 status code (Partial Content) with a Content-Range header indicating the currently satisfiable byte range. For example, a Client-issued HEAD request performed against a continuously aggregating representation hosted on a Server could contain a byte-range header of the form:

```
Range: bytes=0-
```

could return

```
Content-Range: bytes 0-1234567/*
```

from the Server indicating that (1) the complete representation length is unknown (via the "\*" in place of the complete-length field) and (2) that only bytes 0-1234567 were accessible at the time the request was processed. The Client can infer from this response that bytes 0-1234567 of the representation can be requested and returned in a timely fashion (the bytes are immediately available).

## 2.2. Byte-Range Requests Beyond the Randomly Accessible Byte Range

Once a Client has determined that a representation has an indeterminate length and established the byte range that can be accessed, it may want to perform a request that starts within the randomly accessible content range and ends at an indefinite "live" point - a point where the byte-range GET request is fulfilled on-demand as the content is aggregated.

For example, for a large video asset, a client may wish to start a content transfer from the video "key" frame immediately before the point of aggregation and continue the content transfer indefinitely as content is aggregated - in order to support low-latency startup of a live video stream.

Unlike a byte-range Range request, a byte-range Content-Range response header cannot be "open ended", per [RFC7233]:

```
byte-content-range = bytes-unit SP ( byte-range-resp /
unsatisfied-range )

byte-range-resp = byte-range "/" ( complete-length / "*" )

byte-range = first-byte-pos "-" last-byte-pos

unsatisfied-range = "*" complete-length

complete-length = 1*DIGIT
```

last-byte-pos is required in byte-range. So in order to preserve interoperability with existing HTTP clients, servers, proxies, and caches, this document proposes a mechanism for a Client to indicate support for handling an indeterminate-length byte-range response, and a mechanism for a Server to indicate if/when it's providing a indeterminate-length response.

A Client can indicate support for indeterminate-length byte-ranges by providing a Very Large Value for the last-byte-pos in the byte-range request. For example, a Client can perform a byte-range GET request of the form:

```
Range: bytes=1230000-999999999999
```

where the last-byte-pos in the Request is much larger than the last-byte-pos returned in response to an open-ended byte-range request.

### 2.3. Byte-Range Responses Beyond the Randomly Accessible Byte Range

A Server may indicate that it is supplying an continuously aggregating ("live") response by supplying the Client request's last-byte-pos in the Content-Range response header.

For example:

```
Range: bytes=1230000-999999999999
```

could return

```
Content-Range: bytes 1230000-999999999999/*
```

from the Server to indicate that the response will start at byte 1230000 and continues indefinitely to include all aggregated content, as it becomes available.

A Server that doesn't support or supply a continuously aggregating ("live") response should supply the currently satisfiable byte range, as it would with an open-ended byte request.

For example:

```
Range: bytes=1230000-999999999999
```

could return

```
Content-Range: bytes 1230000-1234567/*
```

from the Server to indicate that the response will start at byte 1230000 and end at byte 1234567 and will not include any aggregated content. This is the response expected from a typically-configured HTTP Server - one that doesn't support byte-range requests on aggregated content.

A Client that doesn't receive a response indicating it is continuously aggregating must use other means to access aggregated content (e.g. periodic byte-range polling).

A Server that returns a continuously aggregating ("live") response should return data using chunked transfer coding and not provide a Content-Length header. A 0-length chunk indicates that aggregation of the transferring resource is permanently discontinued.

### 3. Other Applications of Random-Access Aggregating Content

#### 3.1. Requests Starting at the Aggregation ("Live") Point

If a Client would like to start the content transfer at the Aggregation ("live") point without including any randomly accessible portion of the representation, then it should supply the last-byte-pos from the most-recently received byte-range-spec and a Very Large Value for the last-byte-pos in the byte-range request.

For example a HEAD request containing:

```
Range: bytes=0-
```

could return

```
Content-Range: bytes 0-1234567/*
```

and a GET request containing

```
Range: bytes=1234567-999999999999
```

could return

```
Content-Range: bytes 1234567-999999999999/*
```

with the response body starting with continuously aggregating ("live") data and continuing indefinitely.

### 3.2. Shift Buffer Representations

Some representations lend themselves to front-end content deletion in addition to aggregation. While still supporting random access, representations of this type have a portion at the beginning ("0" end) of the randomly accessible region become inaccessible over time. Examples of this kind of representation would be a audio-video time-shift buffer or a rolling log file.

For example a HEAD request containing:

```
Range: bytes=0-
```

could return

```
Content-Range: bytes 1000000-1234567/*
```

indicating that the first 1000000 bytes were not accessible at the time the HEAD request was processed. Subsequent HEAD requests could return:

```
Content-Range: bytes 1000000-1234567/*
```

```
Content-Range: bytes 1010000-1244567/*
```

```
Content-Range: bytes 1020000-1254567/*
```

Note though that the difference between the first-byte-pos and last-byte-pos need not be constant.

The Client could then follow-up with a GET request containing

```
Range: bytes=1020000-999999999999
```

with the Server returning

```
Content-Range: bytes 1020000-999999999999/*
```

with the response body returning bytes 1020000-1254567 immediately and aggregated ("live") data being returned as the content is aggregated.

#### 4. Security Considerations

One potential issue with this recommendation is related to the use of very-large last-byte-pos values. Some Client and Server implementations may not be prepared to deal with byte position values of  $2^{63}$  and beyond. So in applications where there's no expectation that the representation will ever exceed  $2^{63}$ , a value smaller than this value should be used as the Very Large last-byte-pos in a byte-seek request or content-range response.

HTTP State Management Mechanism  
draft-ietf-httpbis-rfc6265bis-01

Abstract

This document defines the HTTP Cookie and Set-Cookie header fields. These header fields can be used by HTTP servers to store state (called cookies) at HTTP user agents, letting the servers maintain a stateful session over the mostly stateless HTTP protocol. Although cookies have many historical infelicities that degrade their security and privacy, the Cookie and Set-Cookie header fields are widely used on the Internet. This document obsoletes RFC 2965.

Note to Readers

Discussion of this draft takes place on the HTTP working group mailing list ([ietf-http-wg@w3.org](mailto:ietf-http-wg@w3.org)), which is archived at <https://lists.w3.org/Archives/Public/ietf-http-wg/> .

Working Group information can be found at <http://httpwg.github.io/> ; source code and issues list for this draft can be found at <https://github.com/httpwg/http-extensions/labels/6265bis> .

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on October 27, 2017.

## 1. Introduction

This document defines the HTTP Cookie and Set-Cookie header fields. Using the Set-Cookie header field, an HTTP server can pass name/value pairs and associated metadata (called cookies) to a user agent. When the user agent makes subsequent requests to the server, the user agent uses the metadata and other information to determine whether to return the name/value pairs in the Cookie header.

Although simple on their surface, cookies have a number of complexities. For example, the server indicates a scope for each cookie when sending it to the user agent. The scope indicates the maximum amount of time in which the user agent should return the cookie, the servers to which the user agent should return the cookie, and the URI schemes for which the cookie is applicable.

For historical reasons, cookies contain a number of security and privacy infelicities. For example, a server can indicate that a given cookie is intended for "secure" connections, but the Secure attribute does not provide integrity in the presence of an active network attacker. Similarly, cookies for a given host are shared across all the ports on that host, even though the usual "same-origin policy" used by web browsers isolates content retrieved via different ports.

There are two audiences for this specification: developers of cookie-generating servers and developers of cookie-consuming user agents.

To maximize interoperability with user agents, servers SHOULD limit themselves to the well-behaved profile defined in Section 4 when generating cookies.

User agents MUST implement the more liberal processing rules defined in Section 5, in order to maximize interoperability with existing servers that do not conform to the well-behaved profile defined in Section 4.

This document specifies the syntax and semantics of these headers as they are actually used on the Internet. In particular, this document does not create new syntax or semantics beyond those in use today. The recommendations for cookie generation provided in Section 4 represent a preferred subset of current server behavior, and even the more liberal cookie processing algorithm provided in Section 5 does not recommend all of the syntactic and semantic variations in use today. Where some existing software differs from the recommended protocol in significant ways, the document contains a note explaining the difference.

Prior to this document, there were at least three descriptions of cookies: the so-called "Netscape cookie specification" [Netscape], RFC 2109 [RFC2109], and RFC 2965 [RFC2965]. However, none of these documents describe how the Cookie and Set-Cookie headers are actually used on the Internet (see [Kri2001] for historical context). In relation to previous IETF specifications of HTTP state management mechanisms, this document requests the following actions:

1. Change the status of [RFC2109] to Historic (it has already been obsoleted by [RFC2965]).
2. Change the status of [RFC2965] to Historic.
3. Indicate that [RFC2965] has been obsoleted by this document.

In particular, in moving RFC 2965 to Historic and obsoleting it, this document deprecates the use of the Cookie2 and Set-Cookie2 header fields.

## 2. Conventions

### 2.1. Conformance Criteria

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

Requirements phrased in the imperative as part of algorithms (such as "strip any leading space characters" or "return false and abort these steps") are to be interpreted with the meaning of the key word ("MUST", "SHOULD", "MAY", etc.) used in introducing the algorithm.

Conformance requirements phrased as algorithms or specific steps can be implemented in any manner, so long as the end result is equivalent. In particular, the algorithms defined in this specification are intended to be easy to understand and are not intended to be performant.

### 2.2. Syntax Notation

This specification uses the Augmented Backus-Naur Form (ABNF) notation of [RFC5234].

The following core rules are included by reference, as defined in [RFC5234], Appendix B.1: ALPHA (letters), CR (carriage return), CRLF (CR LF), CTLs (controls), DIGIT (decimal 0-9), DQUOTE (double quote), HEXDIG (hexadecimal 0-9/A-F/a-f), LF (line feed), NUL (null octet), OCTET (any 8-bit sequence of data except NUL), SP (space), HTAB (horizontal tab), CHAR (any [USASCII] character), VCHAR (any visible [USASCII] character), and WSP (whitespace).

The OWS (optional whitespace) rule is used where zero or more linear whitespace characters MAY appear:

```
OWS          = *( [ obs-fold ] WSP )
              ; "optional" whitespace
obs-fold     = CRLF
```

OWS SHOULD either not be produced or be produced as a single SP character.

### 2.3. Terminology

The terms "user agent", "client", "server", "proxy", and "origin server" have the same meaning as in the HTTP/1.1 specification ([RFC2616], Section 1.3).

The request-host is the name of the host, as known by the user agent, to which the user agent is sending an HTTP request or from which it is receiving an HTTP response (i.e., the name of the host to which it sent the corresponding HTTP request).

The term request-uri is defined in Section 5.1.2 of [RFC2616].

Two sequences of octets are said to case-insensitively match each other if and only if they are equivalent under the `i;ascii-casemap` collation defined in [RFC4790].

The term string means a sequence of non-NUL octets.

### 3. Overview

This section outlines a way for an origin server to send state information to a user agent and for the user agent to return the state information to the origin server.

To store state, the origin server includes a Set-Cookie header in an HTTP response. In subsequent requests, the user agent returns a Cookie request header to the origin server. The Cookie header contains cookies the user agent received in previous Set-Cookie headers. The origin server is free to ignore the Cookie header or use its contents for an application-defined purpose.

Origin servers MAY send a Set-Cookie response header with any response. User agents MAY ignore Set-Cookie headers contained in responses with 100-level status codes but MUST process Set-Cookie headers contained in other responses (including responses with 400- and 500-level status codes). An origin server can include multiple Set-Cookie header fields in a single response. The presence of a Cookie or a Set-Cookie header field does not preclude HTTP caches from storing and reusing a response.

Origin servers SHOULD NOT fold multiple Set-Cookie header fields into a single header field. The usual mechanism for folding HTTP headers fields (i.e., as defined in [RFC2616]) might change the semantics of the Set-Cookie header field because the %x2C (",") character is used by Set-Cookie in a way that conflicts with such folding.

### 3.1. Examples

Using the Set-Cookie header, a server can send the user agent a short string in an HTTP response that the user agent will return in future HTTP requests that are within the scope of the cookie. For example, the server can send the user agent a "session identifier" named SID with the value 31d4d96e407aad42. The user agent then returns the session identifier in subsequent requests.

```
== Server -> User Agent ==
```

```
Set-Cookie: SID=31d4d96e407aad42
```

```
== User Agent -> Server ==
```

```
Cookie: SID=31d4d96e407aad42
```

The server can alter the default scope of the cookie using the Path and Domain attributes. For example, the server can instruct the user agent to return the cookie to every path and every subdomain of example.com.

```
== Server -> User Agent ==
```

```
Set-Cookie: SID=31d4d96e407aad42; Path=/; Domain=example.com
```

```
== User Agent -> Server ==
```

```
Cookie: SID=31d4d96e407aad42
```

As shown in the next example, the server can store multiple cookies at the user agent. For example, the server can store a session identifier as well as the user's preferred language by returning two Set-Cookie header fields. Notice that the server uses the Secure and HttpOnly attributes to provide additional security protections for the more sensitive session identifier (see Section 4.1.2).

== Server -> User Agent ==

```
Set-Cookie: SID=31d4d96e407aad42; Path=/; Secure; HttpOnly
Set-Cookie: lang=en-US; Path=/; Domain=example.com
```

== User Agent -> Server ==

```
Cookie: SID=31d4d96e407aad42; lang=en-US
```

Notice that the Cookie header above contains two cookies, one named SID and one named lang. If the server wishes the user agent to persist the cookie over multiple "sessions" (e.g., user agent restarts), the server can specify an expiration date in the Expires attribute. Note that the user agent might delete the cookie before the expiration date if the user agent's cookie store exceeds its quota or if the user manually deletes the server's cookie.

== Server -> User Agent ==

```
Set-Cookie: lang=en-US; Expires=Wed, 09 Jun 2021 10:18:14 GMT
```

== User Agent -> Server ==

```
Cookie: SID=31d4d96e407aad42; lang=en-US
```

Finally, to remove a cookie, the server returns a Set-Cookie header with an expiration date in the past. The server will be successful in removing the cookie only if the Path and the Domain attribute in the Set-Cookie header match the values used when the cookie was created.

== Server -> User Agent ==

```
Set-Cookie: lang=; Expires=Sun, 06 Nov 1994 08:49:37 GMT
```

== User Agent -> Server ==

```
Cookie: SID=31d4d96e407aad42
```

#### 4. Server Requirements

This section describes the syntax and semantics of a well-behaved profile of the Cookie and Set-Cookie headers.

#### 4.1. Set-Cookie

The Set-Cookie HTTP response header is used to send cookies from the server to the user agent.

##### 4.1.1. Syntax

Informally, the Set-Cookie response header contains the header name "Set-Cookie" followed by a ":" and a cookie. Each cookie begins with a name-value-pair, followed by zero or more attribute-value pairs. Servers SHOULD NOT send Set-Cookie headers that fail to conform to the following grammar:

```

set-cookie-header = "Set-Cookie:" SP set-cookie-string
set-cookie-string = cookie-pair *( ";" SP cookie-av )
cookie-pair       = cookie-name "=" cookie-value
cookie-name       = token
cookie-value      = *cookie-octet / ( DQUOTE *cookie-octet DQUOTE )
cookie-octet      = %x21 / %x23-2B / %x2D-3A / %x3C-5B / %x5D-7E
                  ; US-ASCII characters excluding CTLs,
                  ; whitespace DQUOTE, comma, semicolon,
                  ; and backslash
token             = <token, defined in [RFC2616], Section 2.2>

cookie-av         = expires-av / max-age-av / domain-av /
                  path-av / secure-av / httponly-av /
                  extension-av
expires-av        = "Expires=" sane-cookie-date
sane-cookie-date  =
    <rfc1123-date, defined in [RFC2616], Section 3.3.1>
max-age-av        = "Max-Age=" non-zero-digit *DIGIT
                  ; In practice, both expires-av and max-age-av
                  ; are limited to dates representable by the
                  ; user agent.
non-zero-digit    = %x31-39
                  ; digits 1 through 9
domain-av         = "Domain=" domain-value
domain-value      = <subdomain>
                  ; defined in [RFC1034], Section 3.5, as
                  ; enhanced by [RFC1123], Section 2.1

path-av           = "Path=" path-value
path-value        = *av-octet
secure-av         = "Secure"
httponly-av       = "HttpOnly"
extension-av      = *av-octet
av-octet          = %x20-3A / %x3C-7E
                  ; any CHAR except CTLs or ";"

```

Note that some of the grammatical terms above reference documents that use different grammatical notations than this document (which uses ABNF from [RFC5234]).

The semantics of the cookie-value are not defined by this document.

To maximize compatibility with user agents, servers that wish to store arbitrary data in a cookie-value SHOULD encode that data, for example, using Base64 [RFC4648].

The portions of the set-cookie-string produced by the cookie-av term are known as attributes. To maximize compatibility with user agents, servers SHOULD NOT produce two attributes with the same name in the same set-cookie-string. (See Section 5.3 for how user agents handle this case.)

Servers SHOULD NOT include more than one Set-Cookie header field in the same response with the same cookie-name. (See Section 5.2 for how user agents handle this case.)

If a server sends multiple responses containing Set-Cookie headers concurrently to the user agent (e.g., when communicating with the user agent over multiple sockets), these responses create a "race condition" that can lead to unpredictable behavior.

NOTE: Some existing user agents differ in their interpretation of two-digit years. To avoid compatibility issues, servers SHOULD use the rfc1123-date format, which requires a four-digit year.

NOTE: Some user agents store and process dates in cookies as 32-bit UNIX time\_t values. Implementation bugs in the libraries supporting time\_t processing on some systems might cause such user agents to process dates after the year 2038 incorrectly.

#### 4.1.2. Semantics (Non-Normative)

This section describes simplified semantics of the Set-Cookie header. These semantics are detailed enough to be useful for understanding the most common uses of cookies by servers. The full semantics are described in Section 5.

When the user agent receives a Set-Cookie header, the user agent stores the cookie together with its attributes. Subsequently, when the user agent makes an HTTP request, the user agent includes the applicable, non-expired cookies in the Cookie header.

If the user agent receives a new cookie with the same cookie-name, domain-value, and path-value as a cookie that it has already stored,

the existing cookie is evicted and replaced with the new cookie. Notice that servers can delete cookies by sending the user agent a new cookie with an Expires attribute with a value in the past.

Unless the cookie's attributes indicate otherwise, the cookie is returned only to the origin server (and not, for example, to any subdomains), and it expires at the end of the current session (as defined by the user agent). User agents ignore unrecognized cookie attributes (but not the entire cookie).

#### 4.1.2.1. The Expires Attribute

The Expires attribute indicates the maximum lifetime of the cookie, represented as the date and time at which the cookie expires. The user agent is not required to retain the cookie until the specified date has passed. In fact, user agents often evict cookies due to memory pressure or privacy concerns.

#### 4.1.2.2. The Max-Age Attribute

The Max-Age attribute indicates the maximum lifetime of the cookie, represented as the number of seconds until the cookie expires. The user agent is not required to retain the cookie for the specified duration. In fact, user agents often evict cookies due to memory pressure or privacy concerns.

NOTE: Some existing user agents do not support the Max-Age attribute. User agents that do not support the Max-Age attribute ignore the attribute.

If a cookie has both the Max-Age and the Expires attribute, the Max-Age attribute has precedence and controls the expiration date of the cookie. If a cookie has neither the Max-Age nor the Expires attribute, the user agent will retain the cookie until "the current session is over" (as defined by the user agent).

#### 4.1.2.3. The Domain Attribute

The Domain attribute specifies those hosts to which the cookie will be sent. For example, if the value of the Domain attribute is "example.com", the user agent will include the cookie in the Cookie header when making HTTP requests to example.com, www.example.com, and www.corp.example.com. (Note that a leading %x2E ("."), if present, is ignored even though that character is not permitted, but a trailing %x2E ("."), if present, will cause the user agent to ignore the attribute.) If the server omits the Domain attribute, the user agent will return the cookie only to the origin server.

WARNING: Some existing user agents treat an absent Domain attribute as if the Domain attribute were present and contained the current host name. For example, if example.com returns a Set-Cookie header without a Domain attribute, these user agents will erroneously send the cookie to www.example.com as well.

The user agent will reject cookies unless the Domain attribute specifies a scope for the cookie that would include the origin server. For example, the user agent will accept a cookie with a Domain attribute of "example.com" or of "foo.example.com" from foo.example.com, but the user agent will not accept a cookie with a Domain attribute of "bar.example.com" or of "baz.foo.example.com".

NOTE: For security reasons, many user agents are configured to reject Domain attributes that correspond to "public suffixes". For example, some user agents will reject Domain attributes of "com" or "co.uk". (See Section 5.3 for more information.)

#### 4.1.2.4. The Path Attribute

The scope of each cookie is limited to a set of paths, controlled by the Path attribute. If the server omits the Path attribute, the user agent will use the "directory" of the request-uri's path component as the default value. (See Section 5.1.4 for more details.)

The user agent will include the cookie in an HTTP request only if the path portion of the request-uri matches (or is a subdirectory of) the cookie's Path attribute, where the %x2F ("/") character is interpreted as a directory separator.

Although seemingly useful for isolating cookies between different paths within a given host, the Path attribute cannot be relied upon for security (see Section 8).

#### 4.1.2.5. The Secure Attribute

The Secure attribute limits the scope of the cookie to "secure" channels (where "secure" is defined by the user agent). When a cookie has the Secure attribute, the user agent will include the cookie in an HTTP request only if the request is transmitted over a secure channel (typically HTTP over Transport Layer Security (TLS) [RFC2818]).

Although seemingly useful for protecting cookies from active network attackers, the Secure attribute protects only the cookie's confidentiality. An active network attacker can overwrite Secure cookies from an insecure channel, disrupting their integrity (see Section 8.6 for more details).

#### 4.1.2.6. The HttpOnly Attribute

The HttpOnly attribute limits the scope of the cookie to HTTP requests. In particular, the attribute instructs the user agent to omit the cookie when providing access to cookies via "non-HTTP" APIs (such as a web browser API that exposes cookies to scripts).

Note that the HttpOnly attribute is independent of the Secure attribute: a cookie can have both the HttpOnly and the Secure attribute.

#### 4.1.3. Cookie Name Prefixes

Section 8.5 and 8.6 of this document spell out some of the drawbacks of cookies' historical implementation. In particular, it is impossible for a server to have confidence that a given cookie was set with a particular set of attributes. In order to provide such confidence in a backwards-compatible way, two common sets of requirements can be inferred from the first few characters of the cookie's name.

The normative requirements for the prefixes described below are detailed in the storage model algorithm defined in Section 5.3.

##### 4.1.3.1. The "\_\_Secure-" Prefix

If a cookie's name begins with a case-sensitive match for the string "\_\_Secure-", then the cookie will have been set with a "Secure" attribute.

For example, the following "Set-Cookie" header would be rejected by a conformant user agent, as it does not have a "Secure" attribute.

```
Set-Cookie: __Secure-SID=12345; Domain=example.com
```

Whereas the following "Set-Cookie" header would be accepted:

```
Set-Cookie: __Secure-SID=12345; Domain=example.com; Secure
```

##### 4.1.3.2. The "\_\_Host-" Prefix

If a cookie's name begins with a case-sensitive match for the string "\_\_Host-", then the cookie will have been set with a "Secure" attribute, a "Path" attribute with a value of "/", and no "Domain" attribute.

This combination yields a cookie that hews as closely as a cookie can to treating the origin as a security boundary. The lack of a

"Domain" attribute ensures that the cookie's "host-only-flag" is true, locking the cookie to a particular host, rather than allowing it to span subdomains. Setting the "Path" to "/" means that the cookie is effective for the entire host, and won't be overridden for specific paths. The "Secure" attribute ensures that the cookie is unaltered by non-secure origins, and won't span protocols.

Ports are the only piece of the origin model that "\_\_Host-" cookies continue to ignore.

For example, the following cookies would always be rejected:

```
Set-Cookie: __Host-SID=12345
Set-Cookie: __Host-SID=12345; Secure
Set-Cookie: __Host-SID=12345; Domain=example.com
Set-Cookie: __Host-SID=12345; Domain=example.com; Path=/
Set-Cookie: __Host-SID=12345; Secure; Domain=example.com; Path=/
```

While the would be accepted if set from a secure origin (e.g. "https://example.com/"), and rejected otherwise:

```
Set-Cookie: __Host-SID=12345; Secure; Path=/
```

## 4.2. Cookie

### 4.2.1. Syntax

The user agent sends stored cookies to the origin server in the Cookie header. If the server conforms to the requirements in Section 4.1 (and the user agent conforms to the requirements in Section 5), the user agent will send a Cookie header that conforms to the following grammar:

```
cookie-header = "Cookie:" OWS cookie-string OWS
cookie-string = cookie-pair *( ";" SP cookie-pair )
```

### 4.2.2. Semantics

Each cookie-pair represents a cookie stored by the user agent. The cookie-pair contains the cookie-name and cookie-value the user agent received in the Set-Cookie header.

Notice that the cookie attributes are not returned. In particular, the server cannot determine from the Cookie header alone when a cookie will expire, for which hosts the cookie is valid, for which paths the cookie is valid, or whether the cookie was set with the Secure or HttpOnly attributes.

The semantics of individual cookies in the Cookie header are not defined by this document. Servers are expected to imbue these cookies with application-specific semantics.

Although cookies are serialized linearly in the Cookie header, servers SHOULD NOT rely upon the serialization order. In particular, if the Cookie header contains two cookies with the same name (e.g., that were set with different Path or Domain attributes), servers SHOULD NOT rely upon the order in which these cookies appear in the header.

## 5. User Agent Requirements

This section specifies the Cookie and Set-Cookie headers in sufficient detail that a user agent implementing these requirements precisely can interoperate with existing servers (even those that do not conform to the well-behaved profile described in Section 4).

A user agent could enforce more restrictions than those specified herein (e.g., for the sake of improved security); however, experiments have shown that such strictness reduces the likelihood that a user agent will be able to interoperate with existing servers.

### 5.1. Subcomponent Algorithms

This section defines some algorithms used by user agents to process specific subcomponents of the Cookie and Set-Cookie headers.

#### 5.1.1. Dates

The user agent MUST use an algorithm equivalent to the following algorithm to parse a cookie-date. Note that the various boolean flags defined as a part of the algorithm (i.e., found-time, found-day-of-month, found-month, found-year) are initially "not set".

1. Using the grammar below, divide the cookie-date into date-tokens.

```

cookie-date      = *delimiter date-token-list *delimiter
date-token-list = date-token *( 1*delimiter date-token )
date-token       = 1*non-delimiter

delimiter        = %x09 / %x20-2F / %x3B-40 / %x5B-60 / %x7B-7E
non-delimiter    = %x00-08 / %x0A-1F / DIGIT / ":" / ALPHA / %x7F-FF
non-digit        = %x00-2F / %x3A-FF

day-of-month     = 1*2DIGIT [ non-digit *OCTET ]
month            = ( "jan" / "feb" / "mar" / "apr" /
                    "may" / "jun" / "jul" / "aug" /
                    "sep" / "oct" / "nov" / "dec" ) *OCTET
year             = 2*4DIGIT [ non-digit *OCTET ]
time             = hms-time [ non-digit *OCTET ]
hms-time         = time-field ":" time-field ":" time-field
time-field       = 1*2DIGIT

```

2. Process each date-token sequentially in the order the date-tokens appear in the cookie-date:
  1. If the found-time flag is not set and the token matches the time production, set the found-time flag and set the hour-value, minute-value, and second-value to the numbers denoted by the digits in the date-token, respectively. Skip the remaining sub-steps and continue to the next date-token.
  2. If the found-day-of-month flag is not set and the date-token matches the day-of-month production, set the found-day-of-month flag and set the day-of-month-value to the number denoted by the date-token. Skip the remaining sub-steps and continue to the next date-token.
  3. If the found-month flag is not set and the date-token matches the month production, set the found-month flag and set the month-value to the month denoted by the date-token. Skip the remaining sub-steps and continue to the next date-token.
  4. If the found-year flag is not set and the date-token matches the year production, set the found-year flag and set the year-value to the number denoted by the date-token. Skip the remaining sub-steps and continue to the next date-token.
3. If the year-value is greater than or equal to 70 and less than or equal to 99, increment the year-value by 1900.
4. If the year-value is greater than or equal to 0 and less than or equal to 69, increment the year-value by 2000.

1. NOTE: Some existing user agents interpret two-digit years differently.
5. Abort these steps and fail to parse the cookie-date if:
  - \* at least one of the found-day-of-month, found-month, found-year, or found-time flags is not set,
  - \* the day-of-month-value is less than 1 or greater than 31,
  - \* the year-value is less than 1601,
  - \* the hour-value is greater than 23,
  - \* the minute-value is greater than 59, or
  - \* the second-value is greater than 59.

(Note that leap seconds cannot be represented in this syntax.)

6. Let the parsed-cookie-date be the date whose day-of-month, month, year, hour, minute, and second (in UTC) are the day-of-month-value, the month-value, the year-value, the hour-value, the minute-value, and the second-value, respectively. If no such date exists, abort these steps and fail to parse the cookie-date.
7. Return the parsed-cookie-date as the result of this algorithm.

#### 5.1.2. Canonicalized Host Names

A canonicalized host name is the string generated by the following algorithm:

1. Convert the host name to a sequence of individual domain name labels.
2. Convert each label that is not a Non-Reserved LDH (NR-LDH) label, to an A-label (see Section 2.3.2.1 of [RFC5890] for the former and latter), or to a "punycode label" (a label resulting from the "ToASCII" conversion in Section 4 of [RFC3490]), as appropriate (see Section 6.3 of this specification).
3. Concatenate the resulting labels, separated by a %x2E (".") character.

### 5.1.3. Domain Matching

A string domain-matches a given domain string if at least one of the following conditions hold:

- o The domain string and the string are identical. (Note that both the domain string and the string will have been canonicalized to lower case at this point.)
- o All of the following conditions hold:
  - \* The domain string is a suffix of the string.
  - \* The last character of the string that is not included in the domain string is a %x2E (".") character.
  - \* The string is a host name (i.e., not an IP address).

### 5.1.4. Paths and Path-Match

The user agent MUST use an algorithm equivalent to the following algorithm to compute the default-path of a cookie:

1. Let uri-path be the path portion of the request-uri if such a portion exists (and empty otherwise). For example, if the request-uri contains just a path (and optional query string), then the uri-path is that path (without the %x3F ("?") character or query string), and if the request-uri contains a full absoluteURI, the uri-path is the path component of that URI.
2. If the uri-path is empty or if the first character of the uri-path is not a %x2F ("/") character, output %x2F ("/") and skip the remaining steps.
3. If the uri-path contains no more than one %x2F ("/") character, output %x2F ("/") and skip the remaining step.
4. Output the characters of the uri-path from the first character up to, but not including, the right-most %x2F ("/").

A request-path path-matches a given cookie-path if at least one of the following conditions holds:

- o The cookie-path and the request-path are identical.

Note that this differs from the rules in [RFC3986] for equivalence of the path component, and hence two equivalent paths can have different cookies.

- o The cookie-path is a prefix of the request-path, and the last character of the cookie-path is %x2F ("/").
- o The cookie-path is a prefix of the request-path, and the first character of the request-path that is not included in the cookie-path is a %x2F ("/") character.

## 5.2. The Set-Cookie Header

When a user agent receives a Set-Cookie header field in an HTTP response, the user agent MAY ignore the Set-Cookie header field in its entirety. For example, the user agent might wish to block responses to "third-party" requests from setting cookies (see Section 7.1).

If the user agent does not ignore the Set-Cookie header field in its entirety, the user agent MUST parse the field-value of the Set-Cookie header field as a set-cookie-string (defined below).

NOTE: The algorithm below is more permissive than the grammar in Section 4.1. For example, the algorithm strips leading and trailing whitespace from the cookie name and value (but maintains internal whitespace), whereas the grammar in Section 4.1 forbids whitespace in these positions. User agents use this algorithm so as to interoperate with servers that do not follow the recommendations in Section 4.

A user agent MUST use an algorithm equivalent to the following algorithm to parse a set-cookie-string:

1. If the set-cookie-string contains a %x3B (";") character:
  1. The name-value-pair string consists of the characters up to, but not including, the first %x3B (";"), and the unparsed-attributes consist of the remainder of the set-cookie-string (including the %x3B (";") in question).

Otherwise:

1. The name-value-pair string consists of all the characters contained in the set-cookie-string, and the unparsed-attributes is the empty string.
2. If the name-value-pair string lacks a %x3D ("=") character, ignore the set-cookie-string entirely.
3. The (possibly empty) name string consists of the characters up to, but not including, the first %x3D ("=") character, and the

(possibly empty) value string consists of the characters after the first %x3D ("=") character.

4. Remove any leading or trailing WSP characters from the name string and the value string.
5. If the name string is empty, ignore the set-cookie-string entirely.
6. The cookie-name is the name string, and the cookie-value is the value string.

The user agent MUST use an algorithm equivalent to the following algorithm to parse the unparsed-attributes:

1. If the unparsed-attributes string is empty, skip the rest of these steps.
2. Discard the first character of the unparsed-attributes (which will be a %x3B(";") character).
3. If the remaining unparsed-attributes contains a %x3B(";") character:
  1. Consume the characters of the unparsed-attributes up to, but not including, the first %x3B(";") character.

Otherwise:

1. Consume the remainder of the unparsed-attributes.

Let the cookie-av string be the characters consumed in this step.

4. If the cookie-av string contains a %x3D ("=") character:
  1. The (possibly empty) attribute-name string consists of the characters up to, but not including, the first %x3D ("=") character, and the (possibly empty) attribute-value string consists of the characters after the first %x3D ("=") character.

Otherwise:

1. The attribute-name string consists of the entire cookie-av string, and the attribute-value string is empty.
5. Remove any leading or trailing WSP characters from the attribute-name string and the attribute-value string.

6. Process the attribute-name and attribute-value according to the requirements in the following subsections. (Notice that attributes with unrecognized attribute-names are ignored.)
7. Return to Step 1 of this algorithm.

When the user agent finishes parsing the set-cookie-string, the user agent is said to "receive a cookie" from the request-uri with name cookie-name, value cookie-value, and attributes cookie-attribute-list. (See Section 5.3 for additional requirements triggered by receiving a cookie.)

#### 5.2.1. The Expires Attribute

If the attribute-name case-insensitively matches the string "Expires", the user agent MUST process the cookie-av as follows.

1. Let the expiry-time be the result of parsing the attribute-value as cookie-date (see Section 5.1.1).
2. If the attribute-value failed to parse as a cookie date, ignore the cookie-av.
3. If the expiry-time is later than the last date the user agent can represent, the user agent MAY replace the expiry-time with the last representable date.
4. If the expiry-time is earlier than the earliest date the user agent can represent, the user agent MAY replace the expiry-time with the earliest representable date.
5. Append an attribute to the cookie-attribute-list with an attribute-name of Expires and an attribute-value of expiry-time.

#### 5.2.2. The Max-Age Attribute

If the attribute-name case-insensitively matches the string "Max-Age", the user agent MUST process the cookie-av as follows.

1. If the first character of the attribute-value is not a DIGIT or a "-" character, ignore the cookie-av.
2. If the remainder of attribute-value contains a non-DIGIT character, ignore the cookie-av.
3. Let delta-seconds be the attribute-value converted to an integer.

4. If `delta-seconds` is less than or equal to zero (0), let `expiry-time` be the earliest representable date and time. Otherwise, let the `expiry-time` be the current date and time plus `delta-seconds` seconds.
5. Append an attribute to the `cookie-attribute-list` with an `attribute-name` of `Max-Age` and an `attribute-value` of `expiry-time`.

#### 5.2.3. The Domain Attribute

If the `attribute-name` case-insensitively matches the string "Domain", the user agent MUST process the `cookie-av` as follows.

1. If the `attribute-value` is empty, the behavior is undefined. However, the user agent SHOULD ignore the `cookie-av` entirely.
2. If the first character of the `attribute-value` string is `%x2E` ("."):
  1. Let `cookie-domain` be the `attribute-value` without the leading `%x2E` (".") character.  
  
Otherwise:
    1. Let `cookie-domain` be the entire `attribute-value`.
  3. Convert the `cookie-domain` to lower case.
  4. Append an attribute to the `cookie-attribute-list` with an `attribute-name` of `Domain` and an `attribute-value` of `cookie-domain`.

#### 5.2.4. The Path Attribute

If the `attribute-name` case-insensitively matches the string "Path", the user agent MUST process the `cookie-av` as follows.

1. If the `attribute-value` is empty or if the first character of the `attribute-value` is not `%x2F` ("/"):
  1. Let `cookie-path` be the default-path.  
  
Otherwise:
    1. Let `cookie-path` be the `attribute-value`.
  2. Append an attribute to the `cookie-attribute-list` with an `attribute-name` of `Path` and an `attribute-value` of `cookie-path`.

#### 5.2.5. The Secure Attribute

If the attribute-name case-insensitively matches the string "Secure", the user agent MUST append an attribute to the cookie-attribute-list with an attribute-name of Secure and an empty attribute-value.

#### 5.2.6. The HttpOnly Attribute

If the attribute-name case-insensitively matches the string "HttpOnly", the user agent MUST append an attribute to the cookie-attribute-list with an attribute-name of HttpOnly and an empty attribute-value.

### 5.3. Storage Model

The user agent stores the following fields about each cookie: name, value, expiry-time, domain, path, creation-time, last-access-time, persistent-flag, host-only-flag, secure-only-flag, and http-only-flag.

When the user agent "receives a cookie" from a request-uri with name cookie-name, value cookie-value, and attributes cookie-attribute-list, the user agent MUST process the cookie as follows:

1. A user agent MAY ignore a received cookie in its entirety. For example, the user agent might wish to block receiving cookies from "third-party" responses or the user agent might not wish to store cookies that exceed some size.
2. Create a new cookie with name cookie-name, value cookie-value. Set the creation-time and the last-access-time to the current date and time.
3. If the cookie-attribute-list contains an attribute with an attribute-name of "Max-Age":
  1. Set the cookie's persistent-flag to true.
  2. Set the cookie's expiry-time to attribute-value of the last attribute in the cookie-attribute-list with an attribute-name of "Max-Age".

Otherwise, if the cookie-attribute-list contains an attribute with an attribute-name of "Expires" (and does not contain an attribute with an attribute-name of "Max-Age"):

1. Set the cookie's persistent-flag to true.

2. Set the cookie's expiry-time to attribute-value of the last attribute in the cookie-attribute-list with an attribute-name of "Expires".

Otherwise:

1. Set the cookie's persistent-flag to false.
  2. Set the cookie's expiry-time to the latest representable date.
4. If the cookie-attribute-list contains an attribute with an attribute-name of "Domain":
    1. Let the domain-attribute be the attribute-value of the last attribute in the cookie-attribute-list with an attribute-name of "Domain".

Otherwise:

1. Let the domain-attribute be the empty string.
5. If the user agent is configured to reject "public suffixes" and the domain-attribute is a public suffix:
    1. If the domain-attribute is identical to the canonicalized request-host:
      1. Let the domain-attribute be the empty string.

Otherwise:

1. Ignore the cookie entirely and abort these steps.

NOTE: A "public suffix" is a domain that is controlled by a public registry, such as "com", "co.uk", and "pvt.k12.wy.us". This step is essential for preventing attacker.com from disrupting the integrity of example.com by setting a cookie with a Domain attribute of "com". Unfortunately, the set of public suffixes (also known as "registry controlled domains") changes over time. If feasible, user agents SHOULD use an up-to-date public suffix list, such as the one maintained by the Mozilla project at <http://publicsuffix.org/> .

6. If the domain-attribute is non-empty:
  1. If the canonicalized request-host does not domain-match the domain-attribute:

1. Ignore the cookie entirely and abort these steps.

Otherwise:

1. Set the cookie's host-only-flag to false.
2. Set the cookie's domain to the domain-attribute.

Otherwise:

1. Set the cookie's host-only-flag to true.
  2. Set the cookie's domain to the canonicalized request-host.
7. If the cookie-attribute-list contains an attribute with an attribute-name of "Path", set the cookie's path to attribute-value of the last attribute in the cookie-attribute-list with an attribute-name of "Path". Otherwise, set the cookie's path to the default-path of the request-uri.
  8. If the cookie-attribute-list contains an attribute with an attribute-name of "Secure", set the cookie's secure-only-flag to true. Otherwise, set the cookie's secure-only-flag to false.
  9. If the scheme component of the request-uri does not denote a "secure" protocol (as defined by the user agent), and the cookie's secure-only-flag is true, then abort these steps and ignore the cookie entirely.
  10. If the cookie-attribute-list contains an attribute with an attribute-name of "HttpOnly", set the cookie's http-only-flag to true. Otherwise, set the cookie's http-only-flag to false.
  11. If the cookie was received from a "non-HTTP" API and the cookie's http-only-flag is true, abort these steps and ignore the cookie entirely.
  12. If the cookie's secure-only-flag is not set, and the scheme component of request-uri does not denote a "secure" protocol, then abort these steps and ignore the cookie entirely if the cookie store contains one or more cookies that meet all of the following criteria:
    1. Their name matches the name of the newly-created cookie.
    2. Their secure-only-flag is true.

3. Their domain domain-matches the domain of the newly-created cookie, or vice-versa.
4. The path of the newly-created cookie path-matches the path of the existing cookie.

Note: The path comparison is not symmetric, ensuring only that a newly-created, non-secure cookie does not overlay an existing secure cookie, providing some mitigation against cookie-fixing attacks. That is, given an existing secure cookie named 'a' with a path of '/login', a non-secure cookie named 'a' could be set for a path of '/' or '/foo', but not for a path of '/login' or '/login/en'.

13. If the cookie-name begins with a case-sensitive match for the string "\_\_Secure-", abort these steps and ignore the cookie entirely unless the cookie's secure-only-flag is true.
14. If the cookie-name begins with a case-sensitive match for the string "\_\_Host-", abort these steps and ignore the cookie entirely unless the cookie meets all the following criteria:
  1. The cookie's secure-only-flag is true.
  2. The cookie's host-only-flag is true.
  3. The cookie's path is "/".
15. If the cookie store contains a cookie with the same name, domain, and path as the newly-created cookie:
  1. Let old-cookie be the existing cookie with the same name, domain, and path as the newly-created cookie. (Notice that this algorithm maintains the invariant that there is at most one such cookie.)
  2. If the newly-created cookie was received from a "non-HTTP" API and the old-cookie's http-only-flag is true, abort these steps and ignore the newly created cookie entirely.
  3. Update the creation-time of the newly-created cookie to match the creation-time of the old-cookie.
  4. Remove the old-cookie from the cookie store.
16. Insert the newly-created cookie into the cookie store.

A cookie is "expired" if the cookie has an expiry date in the past.

The user agent MUST evict all expired cookies from the cookie store if, at any time, an expired cookie exists in the cookie store.

At any time, the user agent MAY "remove excess cookies" from the cookie store if the number of cookies sharing a domain field exceeds some implementation-defined upper bound (such as 50 cookies).

At any time, the user agent MAY "remove excess cookies" from the cookie store if the cookie store exceeds some predetermined upper bound (such as 3000 cookies).

When the user agent removes excess cookies from the cookie store, the user agent MUST evict cookies in the following priority order:

1. Expired cookies.
2. Cookies whose secure-only-flag is not set, and which share a domain field with more than a predetermined number of other cookies.
3. Cookies that share a domain field with more than a predetermined number of other cookies.
4. All cookies.

If two cookies have the same removal priority, the user agent MUST evict the cookie with the earliest last-access date first.

When "the current session is over" (as defined by the user agent), the user agent MUST remove from the cookie store all cookies with the persistent-flag set to false.

#### 5.4. The Cookie Header

The user agent includes stored cookies in the Cookie HTTP request header.

When the user agent generates an HTTP request, the user agent MUST NOT attach more than one Cookie header field.

A user agent MAY omit the Cookie header in its entirety. For example, the user agent might wish to block sending cookies during "third-party" requests from setting cookies (see Section 7.1).

If the user agent does attach a Cookie header field to an HTTP request, the user agent MUST send the cookie-string (defined below) as the value of the header field.

The user agent MUST use an algorithm equivalent to the following algorithm to compute the cookie-string from a cookie store and a request-uri:

1. Let cookie-list be the set of cookies from the cookie store that meets all of the following requirements:

- \* Either:

- + The cookie's host-only-flag is true and the canonicalized request-host is identical to the cookie's domain.

- Or:

- + The cookie's host-only-flag is false and the canonicalized request-host domain-matches the cookie's domain.

- \* The request-uri's path path-matches the cookie's path.

- \* If the cookie's secure-only-flag is true, then the request-uri's scheme must denote a "secure" protocol (as defined by the user agent).

NOTE: The notion of a "secure" protocol is not defined by this document. Typically, user agents consider a protocol secure if the protocol makes use of transport-layer security, such as SSL or TLS. For example, most user agents consider "https" to be a scheme that denotes a secure protocol.

- \* If the cookie's http-only-flag is true, then exclude the cookie if the cookie-string is being generated for a "non-HTTP" API (as defined by the user agent).

2. The user agent SHOULD sort the cookie-list in the following order:

- \* Cookies with longer paths are listed before cookies with shorter paths.

- \* Among cookies that have equal-length path fields, cookies with earlier creation-times are listed before cookies with later creation-times.

NOTE: Not all user agents sort the cookie-list in this order, but this order reflects common practice when this document was written, and, historically, there have been servers that (erroneously) depended on this order.

3. Update the last-access-time of each cookie in the cookie-list to the current date and time.
4. Serialize the cookie-list into a cookie-string by processing each cookie in the cookie-list in order:
  1. Output the cookie's name, the %x3D ("=") character, and the cookie's value.
  2. If there is an unprocessed cookie in the cookie-list, output the characters %x3B and %x20 ("; ").

NOTE: Despite its name, the cookie-string is actually a sequence of octets, not a sequence of characters. To convert the cookie-string (or components thereof) into a sequence of characters (e.g., for presentation to the user), the user agent might wish to try using the UTF-8 character encoding [RFC3629] to decode the octet sequence. This decoding might fail, however, because not every sequence of octets is valid UTF-8.

## 6. Implementation Considerations

### 6.1. Limits

Practical user agent implementations have limits on the number and size of cookies that they can store. General-use user agents SHOULD provide each of the following minimum capabilities:

- o At least 4096 bytes per cookie (as measured by the sum of the length of the cookie's name, value, and attributes).
- o At least 50 cookies per domain.
- o At least 3000 cookies total.

Servers SHOULD use as few and as small cookies as possible to avoid reaching these implementation limits and to minimize network bandwidth due to the Cookie header being included in every request.

Servers SHOULD gracefully degrade if the user agent fails to return one or more cookies in the Cookie header because the user agent might evict any cookie at any time on orders from the user.

### 6.2. Application Programming Interfaces

One reason the Cookie and Set-Cookie headers use such esoteric syntax is that many platforms (both in servers and user agents) provide a string-based application programming interface (API) to cookies,

requiring application-layer programmers to generate and parse the syntax used by the Cookie and Set-Cookie headers, which many programmers have done incorrectly, resulting in interoperability problems.

Instead of providing string-based APIs to cookies, platforms would be well-served by providing more semantic APIs. It is beyond the scope of this document to recommend specific API designs, but there are clear benefits to accepting an abstract "Date" object instead of a serialized date string.

### 6.3. IDNA Dependency and Migration

IDNA2008 [RFC5890] supersedes IDNA2003 [RFC3490]. However, there are differences between the two specifications, and thus there can be differences in processing (e.g., converting) domain name labels that have been registered under one from those registered under the other. There will be a transition period of some time during which IDNA2003-based domain name labels will exist in the wild. User agents SHOULD implement IDNA2008 [RFC5890] and MAY implement [UTS46] or [RFC5895] in order to facilitate their IDNA transition. If a user agent does not implement IDNA2008, the user agent MUST implement IDNA2003 [RFC3490].

## 7. Privacy Considerations

Cookies are often criticized for letting servers track users. For example, a number of "web analytics" companies use cookies to recognize when a user returns to a web site or visits another web site. Although cookies are not the only mechanism servers can use to track users across HTTP requests, cookies facilitate tracking because they are persistent across user agent sessions and can be shared between hosts.

### 7.1. Third-Party Cookies

Particularly worrisome are so-called "third-party" cookies. In rendering an HTML document, a user agent often requests resources from other servers (such as advertising networks). These third-party servers can use cookies to track the user even if the user never visits the server directly. For example, if a user visits a site that contains content from a third party and then later visits another site that contains content from the same third party, the third party can track the user between the two sites.

Some user agents restrict how third-party cookies behave. For example, some of these user agents refuse to send the Cookie header in third-party requests. Others refuse to process the Set-Cookie

header in responses to third-party requests. User agents vary widely in their third-party cookie policies. This document grants user agents wide latitude to experiment with third-party cookie policies that balance the privacy and compatibility needs of their users. However, this document does not endorse any particular third-party cookie policy.

Third-party cookie blocking policies are often ineffective at achieving their privacy goals if servers attempt to work around their restrictions to track users. In particular, two collaborating servers can often track users without using cookies at all by injecting identifying information into dynamic URLs.

## 7.2. User Controls

User agents SHOULD provide users with a mechanism for managing the cookies stored in the cookie store. For example, a user agent might let users delete all cookies received during a specified time period or all the cookies related to a particular domain. In addition, many user agents include a user interface element that lets users examine the cookies stored in their cookie store.

User agents SHOULD provide users with a mechanism for disabling cookies. When cookies are disabled, the user agent MUST NOT include a Cookie header in outbound HTTP requests and the user agent MUST NOT process Set-Cookie headers in inbound HTTP responses.

Some user agents provide users the option of preventing persistent storage of cookies across sessions. When configured thusly, user agents MUST treat all received cookies as if the persistent-flag were set to false. Some popular user agents expose this functionality via "private browsing" mode [Aggarwal2010].

Some user agents provide users with the ability to approve individual writes to the cookie store. In many common usage scenarios, these controls generate a large number of prompts. However, some privacy-conscious users find these controls useful nonetheless.

## 7.3. Expiration Dates

Although servers can set the expiration date for cookies to the distant future, most user agents do not actually retain cookies for multiple decades. Rather than choosing gratuitously long expiration periods, servers SHOULD promote user privacy by selecting reasonable cookie expiration periods based on the purpose of the cookie. For example, a typical session identifier might reasonably be set to expire in two weeks.

## 8. Security Considerations

### 8.1. Overview

Cookies have a number of security pitfalls. This section overviews a few of the more salient issues.

In particular, cookies encourage developers to rely on ambient authority for authentication, often becoming vulnerable to attacks such as cross-site request forgery [CSRF]. Also, when storing session identifiers in cookies, developers often create session fixation vulnerabilities.

Transport-layer encryption, such as that employed in HTTPS, is insufficient to prevent a network attacker from obtaining or altering a victim's cookies because the cookie protocol itself has various vulnerabilities (see "Weak Confidentiality" and "Weak Integrity", below). In addition, by default, cookies do not provide confidentiality or integrity from network attackers, even when used in conjunction with HTTPS.

### 8.2. Ambient Authority

A server that uses cookies to authenticate users can suffer security vulnerabilities because some user agents let remote parties issue HTTP requests from the user agent (e.g., via HTTP redirects or HTML forms). When issuing those requests, user agents attach cookies even if the remote party does not know the contents of the cookies, potentially letting the remote party exercise authority at an unwary server.

Although this security concern goes by a number of names (e.g., cross-site request forgery, confused deputy), the issue stems from cookies being a form of ambient authority. Cookies encourage server operators to separate designation (in the form of URLs) from authorization (in the form of cookies). Consequently, the user agent might supply the authorization for a resource designated by the attacker, possibly causing the server or its clients to undertake actions designated by the attacker as though they were authorized by the user.

Instead of using cookies for authorization, server operators might wish to consider entangling designation and authorization by treating URLs as capabilities. Instead of storing secrets in cookies, this approach stores secrets in URLs, requiring the remote entity to supply the secret itself. Although this approach is not a panacea, judicious application of these principles can lead to more robust security.

### 8.3. Clear Text

Unless sent over a secure channel (such as TLS), the information in the Cookie and Set-Cookie headers is transmitted in the clear.

1. All sensitive information conveyed in these headers is exposed to an eavesdropper.
2. A malicious intermediary could alter the headers as they travel in either direction, with unpredictable results.
3. A malicious client could alter the Cookie header before transmission, with unpredictable results.

Servers SHOULD encrypt and sign the contents of cookies (using whatever format the server desires) when transmitting them to the user agent (even when sending the cookies over a secure channel). However, encrypting and signing cookie contents does not prevent an attacker from transplanting a cookie from one user agent to another or from replaying the cookie at a later time.

In addition to encrypting and signing the contents of every cookie, servers that require a higher level of security SHOULD use the Cookie and Set-Cookie headers only over a secure channel. When using cookies over a secure channel, servers SHOULD set the Secure attribute (see Section 4.1.2.5) for every cookie. If a server does not set the Secure attribute, the protection provided by the secure channel will be largely moot.

For example, consider a webmail server that stores a session identifier in a cookie and is typically accessed over HTTPS. If the server does not set the Secure attribute on its cookies, an active network attacker can intercept any outbound HTTP request from the user agent and redirect that request to the webmail server over HTTP. Even if the webmail server is not listening for HTTP connections, the user agent will still include cookies in the request. The active network attacker can intercept these cookies, replay them against the server, and learn the contents of the user's email. If, instead, the server had set the Secure attribute on its cookies, the user agent would not have included the cookies in the clear-text request.

### 8.4. Session Identifiers

Instead of storing session information directly in a cookie (where it might be exposed to or replayed by an attacker), servers commonly store a nonce (or "session identifier") in a cookie. When the server receives an HTTP request with a nonce, the server can look up state information associated with the cookie using the nonce as a key.

Using session identifier cookies limits the damage an attacker can cause if the attacker learns the contents of a cookie because the nonce is useful only for interacting with the server (unlike non-nonce cookie content, which might itself be sensitive). Furthermore, using a single nonce prevents an attacker from "splicing" together cookie content from two interactions with the server, which could cause the server to behave unexpectedly.

Using session identifiers is not without risk. For example, the server SHOULD take care to avoid "session fixation" vulnerabilities. A session fixation attack proceeds in three steps. First, the attacker transplants a session identifier from his or her user agent to the victim's user agent. Second, the victim uses that session identifier to interact with the server, possibly imbuing the session identifier with the user's credentials or confidential information. Third, the attacker uses the session identifier to interact with server directly, possibly obtaining the user's authority or confidential information.

#### 8.5. Weak Confidentiality

Cookies do not provide isolation by port. If a cookie is readable by a service running on one port, the cookie is also readable by a service running on another port of the same server. If a cookie is writable by a service on one port, the cookie is also writable by a service running on another port of the same server. For this reason, servers SHOULD NOT both run mutually distrusting services on different ports of the same host and use cookies to store security-sensitive information.

Cookies do not provide isolation by scheme. Although most commonly used with the http and https schemes, the cookies for a given host might also be available to other schemes, such as ftp and gopher. Although this lack of isolation by scheme is most apparent in non-HTTP APIs that permit access to cookies (e.g., HTML's document.cookie API), the lack of isolation by scheme is actually present in requirements for processing cookies themselves (e.g., consider retrieving a URI with the gopher scheme via HTTP).

Cookies do not always provide isolation by path. Although the network-level protocol does not send cookies stored for one path to another, some user agents expose cookies via non-HTTP APIs, such as HTML's document.cookie API. Because some of these user agents (e.g., web browsers) do not isolate resources received from different paths, a resource retrieved from one path might be able to access cookies stored for another path.

## 8.6. Weak Integrity

Cookies do not provide integrity guarantees for sibling domains (and their subdomains). For example, consider `foo.example.com` and `bar.example.com`. The `foo.example.com` server can set a cookie with a Domain attribute of `"example.com"` (possibly overwriting an existing `"example.com"` cookie set by `bar.example.com`), and the user agent will include that cookie in HTTP requests to `bar.example.com`. In the worst case, `bar.example.com` will be unable to distinguish this cookie from a cookie it set itself. The `foo.example.com` server might be able to leverage this ability to mount an attack against `bar.example.com`.

Even though the Set-Cookie header supports the Path attribute, the Path attribute does not provide any integrity protection because the user agent will accept an arbitrary Path attribute in a Set-Cookie header. For example, an HTTP response to a request for `http://example.com/foo/bar` can set a cookie with a Path attribute of `"/qux"`. Consequently, servers SHOULD NOT both run mutually distrusting services on different paths of the same host and use cookies to store security-sensitive information.

An active network attacker can also inject cookies into the Cookie header sent to `https://example.com/` by impersonating a response from `http://example.com/` and injecting a Set-Cookie header. The HTTPS server at `example.com` will be unable to distinguish these cookies from cookies that it set itself in an HTTPS response. An active network attacker might be able to leverage this ability to mount an attack against `example.com` even if `example.com` uses HTTPS exclusively.

Servers can partially mitigate these attacks by encrypting and signing the contents of their cookies. However, using cryptography does not mitigate the issue completely because an attacker can replay a cookie he or she received from the authentic `example.com` server in the user's session, with unpredictable results.

Finally, an attacker might be able to force the user agent to delete cookies by storing a large number of cookies. Once the user agent reaches its storage limit, the user agent will be forced to evict some cookies. Servers SHOULD NOT rely upon user agents retaining cookies.

## 8.7. Reliance on DNS

Cookies rely upon the Domain Name System (DNS) for security. If the DNS is partially or fully compromised, the cookie protocol might fail to provide the security properties required by applications.

## 9. IANA Considerations

The permanent message header field registry (see [RFC3864]) needs to be updated with the following registrations.

### 9.1. Cookie

Header field name: Cookie

Applicable protocol: http

Status: standard

Author/Change controller: IETF

Specification document: this specification (Section 5.4)

### 9.2. Set-Cookie

Header field name: Set-Cookie

Applicable protocol: http

Status: standard

Author/Change controller: IETF

Specification document: this specification (Section 5.2)

#### Appendix A. Changes

##### A.1. draft-ietf-httpbis-rfc6265bis-00

- o Port [RFC6265] to Markdown. No (intentional) normative changes.

##### A.2. draft-ietf-httpbis-rfc6265bis-01

- o Fixes to formatting caused by mistakes in the initial port to Markdown:
  - \* <https://github.com/httpwg/http-extensions/issues/243>
  - \* <https://github.com/httpwg/http-extensions/issues/246>
- o Addresses errata 3444 by updating the "path-value" and "extension-av" grammar, errata 4148 by updating the "day-of-month", "year", and "time" grammar, and errata 3663 by adding the requested note. [https://www.rfc-editor.org/errata\\_search.php?rfc=6265](https://www.rfc-editor.org/errata_search.php?rfc=6265)
- o Dropped "Cookie2" and "Set-Cookie2" from the IANA Considerations section: <https://github.com/httpwg/http-extensions/issues/247>
- o Merged the recommendations from [draft-ietf-httpbis-cookie-alone], removing the ability for a non-secure origin to set cookies with a 'secure' flag, and to overwrite cookies whose 'secure' flag is true.
- o Merged the recommendations from [draft-ietf-httpbis-cookie-prefixes], adding "\_\_Secure-" and "\_\_Host-" cookie name prefix processing instructions.

## Appendix B. Acknowledgements

This document is a minor update of RFC 6265, adding small features, and aligning the specification with the reality of today's deployments. Here, we're standing upon the shoulders of giants.
