Cryptographic Algorithm Implementation Requirements and Usage Guidance
for Encapsulating Security Payload (ESP) and Authentication Header (AH)
draft-ietf-ipsecme-rfc7321bis-06

Abstract

This document updates the Cryptographic Algorithm Implementation Requirements for ESP and AH. The goal of these document is to enable ESP and AH to benefit from cryptography that is up to date while making IPsec interoperable.

This document obsoletes RFC 7321.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on December 21, 2017.

1. Introduction

The Encapsulating Security Payload (ESP) [RFC4303] and the Authentication Header (AH) [RFC4302] are the mechanisms for applying cryptographic protection to data being sent over an IPsec Security Association (SA) [RFC4301].

This document provides guidance and recommendations so that ESP and AH can be used with a cryptographic algorithms that are up to date. The challenge of such document is to make sure that over the time IPsec implementations can use secure and up-to-date cryptographic algorithms while keeping IPsec interoperable.

1.1. Updating Algorithm Implementation Requirements and Usage Guidance

The field of cryptography evolves continuously. New stronger algorithms appear and existing algorithms are found to be less secure than originally thought. Therefore, algorithm implementation requirements and usage guidance need to be updated from time to time to reflect the new reality. The choices for algorithms must be conservative to minimize the risk of algorithm compromise. Algorithms need to be suitable for a wide variety of CPU architectures and device deployments ranging from high end bulk encryption devices to small low-power IoT devices.

The algorithm implementation requirements and usage guidance may need to change over time to adapt to the changing world. For this reason, the selection of mandatory-to-implement algorithms was removed from the main IKEv2 specification and placed in a separate document.

1.2. Updating Algorithm Requirement Levels

The mandatory-to-implement algorithm of tomorrow should already be available in most implementations of AH/ESP by the time it is made mandatory. This document attempts to identify and introduce those algorithms for future mandatory-to-implement status. There is no guarantee that the algorithms in use today may become mandatory in the future. Published algorithms are continuously subjected to cryptographic attack and may become too weak or could become completely broken before this document is updated.

This document only provides recommendations for the mandatory-to-implement algorithms and algorithms too weak that are recommended not to be implemented. As a result, any algorithm listed at the IPsec IANA registry not mentioned in this document MAY be implemented. It is expected that this document will be updated over time and next versions will only mention algorithms which status has evolved. For clarification when an algorithm has been mentioned in [RFC7321], this document states explicitly the update of the status.

Although this document updates the algorithms to keep the AH/ESP communication secure over time, it also aims at providing recommendations so that AH/ESP implementations remain interoperable. AH/ESP interoperability is addressed by an incremental introduction or deprecation of algorithms. In addition, this document also considers the new use cases for AH/ESP deployment, such as Internet of Things (IoT).

It is expected that deprecation of an algorithm is performed gradually. This provides time for various implementations to update their implemented algorithms while remaining interoperable. Unless

there are strong security reasons, an algorithm is expected to be downgraded from MUST to MUST- or SHOULD, instead of MUST NOT. Similarly, an algorithm that has not been mentioned as mandatory-to-implement is expected to be introduced with a SHOULD instead of a MUST.

The current trend toward Internet of Things and its adoption of AH/ESP requires this specific use case to be taken into account as well. IoT devices are resource constrained devices and their choice of algorithms are motivated by minimizing the footprint of the code, the computation effort and the size of the messages to send. This document indicates "(IoT)" when a specified algorithm is specifically listed for IoT devices. Requirement levels that are marked as "IoT" apply to IoT devices and to server-side implementations that might presumably need to interoperate with them, including any general-purpose VPN gateways.

1.3. Document Audience

The recommendations of this document mostly target AH/ESP implementers as implementations need to meet both high security expectations as well as high interoperability between various vendors and with different versions. Interoperability requires a smooth move to more secure cipher suites. This may differ from a user point of view that may deploy and configure AH/ESP with only the safest cipher suite.

This document does not give any recommendations for the use of algorithms, it only gives implementation recommendations for implementations. The use of algorithms by users is dictated by the security policy requirements for that specific user, and are outside the scope of this document.

The algorithms considered here are listed by the IANA as part of the IKEv2 parameters. IKEv1 is out of scope of this document. IKEv1 is deprecated and the recommendations of this document must not be considered for IKEv1, nor IKEv1 parameters be considered by this document.

The IANA registry for Internet Key Exchange Version 2 (IKEv2) Parameters contains some entries that are not for use with ESP or AH. This document does not modify the status of those algorithms.

2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and

"OPTIONAL" in this document are to be interpreted as described in [RFC2119].

We define some additional terms here:

- SHOULD+ This term means the same as SHOULD. However, it is likely that an algorithm marked as SHOULD+ will be promoted at some future time to be a MUST.
- SHOULD- This term means the same as SHOULD. However, an algorithm marked as SHOULD- may be deprecated to a MAY in a future version of this document.
- MUST- This term means the same as MUST. However, we expect at some point that this algorithm will no longer be a MUST in a future document. Although its status will be determined at a later time, it is reasonable to expect that if a future revision of a document alters the status of a MUST-algorithm, it will remain at least a SHOULD or a SHOULD-level.
- IoT stands for Internet of Things.

3. Manual Keying

Manual Keying SHOULD NOT be used as it is inherently dangerous. Without any secure keying protocol such a IKE, IPsec does not offer Perfect Forward Secrecy ("PFS") protection and there is no entity to ensure refreshing of session keys, tracking SPI uniqueness and ensuring nonces, IVs and counters are never re-used. This document was written for deploying ESP/AH using IKE ([RFC7296]) and assumes that keying happens using IKE version 2 or higher.

If Manual Keying is used regardless, Counter Mode algorithms such as ENCR_AES_CTR, ENCR_AES_CCM, ENCR_AES_GCM and ENCR_CHACHA20_POLY1305 MUST NOT be used as it is incompatible with a secure and persistent handling of the counter, as explained in the Security Considerations Section of [RFC3686]. This particularly applies to IoT devices that have no state across reboots. As of publication date of this document, ENCR_AES_CBC is the only Mandatory-To-Implement encryption algorithm suitable for Manual Keying.

4. Encryption must be Authenticated

Encryption without authentication is not effective and MUST NOT be used. IPsec offers three ways to provide both encryption and authentication:

- o ESP with an AEAD cipher
- o ESP with a non-AEAD cipher + authentication
- o ESP with a non-AEAD cipher + AH with authentication

The fastest and most modern method is to use ESP with a combined mode cipher such as an AEAD cipher that handles encryption/decryption and authentication in a single step. In this case, the AEAD cipher is set as the encryption algorithm and the authentication algorithm is set to none. Examples of this are ENCR_AES_GCM_16 and ENCR_CHACHA20_POLY1305.

A more traditional approach is to use ESP with an encryption and an authentication algorithm. This approach is slower, as the data has to be processed twice, once for encryption/decryption and once for authentication. An example of this is ENCR_AES_CBC combined with AUTH_HMAC_SHA2_512_256.

The last method that can be used is ESP+AH. This method is NOT RECOMMENDED. It is the slowest method and also takes up more octets due to the double header of ESP+AH, resulting in a smaller effective MTU for the encrypted data. With this method, ESP is only used for confidentiality without an authentication algorithm and a second IPsec protocol of type AH is used for authentication. An example of this is ESP with ENCR_AES_CBC with AH with AUTH_HMAC_SHA2_512_256.

5. ESP Encryption Algorithms

Name	Status	AEAD	Comment
ENCR_DES_IV64	MUST NOT	No	UNSPECIFIED
ENCR_DES	MUST NOT	No	[RFC2405]
ENCR_3DES	SHOULD NOT	No	[RFC2451]
ENCR_BLOWFISH	MUST NOT	No	[RFC2451]
ENCR_3IDEA	MUST NOT	No	UNSPECIFIED
ENCR_DES_IV32	MUST NOT	No	UNSPECIFIED
ENCR_NULL	MUST	No	[RFC2410]
ENCR_AES_CBC	MUST	No	[RFC3602][1]
ENCR_AES_CCM_8	SHOULD(IoT)	Yes	[RFC4309]
ENCR_AES_GCM_16	MUST	Yes	[RFC4106][1]
ENCR_CHACHA20_POLY1305	SHOULD	Yes	[RFC7634]

[1] - This requirement level is for 128-bit and 256-bit keys. 192-bit keys remain at MAY level. (IoT) - This requirement is for interoperability with IoT. Only 128-bit keys are at the given level.

IPsec sessions may have very long life time, and carry multiple packets, so there is a need to move to 256-bit keys in the long term. For that purpose the requirement level for 128 bit keys and 256 bit keys are at MUST (when applicable). In that sense 256 bit keys status has been raised from MAY in RFC7321 to MUST.

IANA has allocated codes for cryptographic algorithms that have not been specified by the IETF. Such algorithms are noted as UNSPECIFIED. Usually, the use of these algorithms is limited to specific cases, and the absence of specification makes interoperability difficult for IPsec communications. These algorithms were not been mentioned in [RFC7321] and this document clarify that such algorithms MUST NOT be implemented for IPsec communications.

Similarly IANA also allocated code points for algorithms that are not expected to be used to secure IPsec communications. Such algorithms are noted as Non IPsec. As a result, these algorithms MUST NOT be implemented.

Various older and not well tested and never widely implemented ciphers have been changed to MUST NOT.

ENCR_3DES status has been downgraded from MAY in RFC7321 to SHOULD NOT. ENCR_CHACHA20_POLY1305 is a more modern approach alternative for ENCR_3DES than ENCR_AES_CBC and so it expected to be favored to replace ENCR_3DES.

ENCR_BLOWFISH has been downgraded to MUST NOT as it has been deprecated for years by TWOFISH, which is not standardized for ESP and therefore not listed in this document. Some implementations support TWOFISH using a private range number.

ENCR_NULL status was set to MUST in [RFC7321] and remains a MUST to enable the use of ESP with only authentication which is preferred over AH due to NAT traversal. ENCR_NULL is expected to remain MUST by protocol requirements.

ENCR_AES_CBC status remains at MUST. ENCR_AES_CBC MUST be implemented in order to enable interoperability between implementations that followed RFC7321. However, there is a trend for the industry to move to AEAD encryption, and the overhead of ENCR_AES_CBC remains quite large so it is expected to be replaced by AEAD algorithms in the long term.

ENCR_AES_CCM_8 status was set to MAY in [RFC7321] and has been raised from MAY to SHOULD in order to interact with Internet of Things devices. As this case is not a general use case for VPNs, its status is expected to remain as SHOULD.

ENCR_AES_GCM_16 status has been updated from SHOULD+ to MUST in order to favor the use of authenticated encryption and AEAD algorithms. ENCR_AES_GCM_16 has been widely implemented for ESP due to its increased performance and key longevity compared to ENCR_AES_CBC.

ENCR_CHACHA20_POLY1305 was not ready to be considered at the time of RFC7321. It has been recommended by the CRFG and others as an alternative to AES-CBC and AES-GCM. It is also being standardized for ESP for the same reasons. At the time of writing, there are not enough ESP implementations of ENCR_CHACHA20_POLY1305 to be able to introduce it at the SHOULD+ level. Its status has been set to SHOULD and is expected to become MUST in the long term.

6. ESP and AH Authentication Algorithms

Authentication algorithm recommendations in this section are targeting two types of communications:

- o Authenticated only communications without encryption, such as ESP with NULL encryption or AH communications.
- o Communications that are encrypted with non-AEAD algorithm which MUST be combined with an authentication algorithm.

Name	Status	Comment
AUTH_NONE	MUST / MUST NOT	[RFC7296] AEAD
AUTH_HMAC_MD5_96	MUST NOT	[RFC2403][RFC7296]
AUTH_HMAC_SHA1_96	MUST-	[RFC2404][RFC7296]
AUTH_DES_MAC	MUST NOT	[UNSPECIFIED]
AUTH_KPDK_MD5	MUST NOT	[UNSPECIFIED]
AUTH_AES_XCBC_96	SHOULD	[RFC3566][RFC7296] (IoT)
AUTH_AES_128_GMAC	MAY	[RFC4543]
AUTH_AES_256_GMAC	MAY	[RFC4543]
AUTH_HMAC_SHA2_256_128	MUST	[RFC4868]
AUTH_HMAC_SHA2_512_256	SHOULD	[RFC4868]

(IoT) - This requirement is for interoperability with IoT

AUTH_NONE has been downgraded from MAY in RFC7321 to MUST NOT. The only case where AUTH_NONE is acceptable is when authenticated encryption algorithms are selected from Section 5. In all other cases, AUTH_NONE MUST NOT be selected. As ESP and AH both provide authentication, one may be tempted to combine these protocols to provide authentication. As mentioned by RFC7321, it is NOT RECOMMENDED to use ESP with NULL authentication - with non authenticated encryption - in conjunction with AH; some configurations of this combination of services have been shown to be insecure [PD10]. In addition, AUTH_NONE authentication cannot be combined with ESP NULL encryption.

AUTH_HMAC_MD5_96 and AUTH_KPDK_MD5 were not mentioned in RFC7321. As MD5 is known to be vulnerable to collisions, these algorithms MUST NOT be used.

AUTH_HMAC_SHA1_96 has been downgraded from MUST in RFC7321 to MUST-as there is an industry-wide trend to deprecate its usage.

AUTH_DES_MAC was not mentioned in RFC7321. As DES is known to be vulnerable, it MUST NOT be used.

AUTH_AES_XCBC_96 is set as SHOULD only in the scope of IoT, as Internet of Things deployments tend to prefer AES based HMAC functions in order to avoid implementing SHA2. For the wide VPN deployment, as it has not been widely adopted, it has been downgraded from SHOULD to MAY.

AUTH_AES_128_GMAC status has been downgraded from SHOULD+ to MAY. Along with AUTH_AES_192_GMAC and AUTH_AES_256_GMAC, these algorithms should only be used for AH and not for ESP. If using ENCR_NULL, AUTH_HMAC_SHA2_256_128 is recommended for integrity. If using AES-GMAC in ESP without authentication, ENCR_NULL_AUTH_AES_GMAC is recommended. Therefore, these ciphers are kept at MAY.

AUTH_HMAC_SHA2_256_128 was not mentioned in RFC7321, as no SHA2 based authentication was mentioned. AUTH_HMAC_SHA2_256_128 MUST be implemented in order to replace AUTH_HMAC_SHA1_96. Note that due to a long standing common implementation bug of this algorithm that truncates the hash at 96-bits instead of 128-bits, it is recommended that implementations prefer AUTH_HMAC_SHA2_512_256 over AUTH_HMAC_SHA2_256_128 if they implement AUTH_HMAC_SHA2_512_256.

AUTH_HMAC_SHA2_512_256 SHOULD be implemented as a future replacement of AUTH_HMAC_SHA2_256_128 or when stronger security is required. This value has been preferred to AUTH_HMAC_SHA2_384, as the additional overhead of AUTH_HMAC_SHA2_512 is negligible.

7. ESP and AH Compression Algorithms

Name	Status	Comment
IPCOMP_OUI	MUST NOT	UNSPECIFIED
IPCOMP_DEFLATE	MAY	[RFC2393]
IPCOMP_LZS	MAY	[RFC2395]
IPCOMP_LZJH	MAY	[RFC3051]

(IoT) - This requirement is for interoperability with IoT

Compression was not mentioned in RFC7321. As it is not widely deployed, it remains optional and at the MAY-level.

8. Summary of Changes from RFC 7321

The following table summarizes the changes from RFC 7321.

RFC EDITOR: PLEASE REMOVE THIS PARAGRAPH AND REPLACE XXXX IN THE TABLE BELOW WITH THE NUMBER OF THIS RFC

Algorithm	RFC 7321	RFC XXXX
ENCR_AES_GCM_16	SHOULD+	MUST
ENCR_AES_CCM_8	MAY	SHOULD
ENCR_AES_CTR	MAY	(*)
ENCR_3DES	MAY	SHOULD NOT
AUTH_HMAC_SHA1_96	MUST	MUST-
AUTH_AES_128_GMAC	SHOULD+	MAY
AUTH_NONE	MAY	MUST / MUST NOT

(*) This algorithm is not mentioned in the above sections, so it defaults to MAY.

9. Acknowledgements

Some of the wording in this document was adapted from [RFC7321], the document that this one obsoletes, which was written by D. McGrew and P. Hoffman.

10. IANA Considerations

This document has no IANA actions.

11. Security Considerations

The security of a system that uses cryptography depends on both the strength of the cryptographic algorithms chosen and the strength of the keys used with those algorithms. The security also depends on the engineering and administration of the protocol used by the system to ensure that there are no non-cryptographic ways to bypass the security of the overall system.

This document concerns itself with the selection of cryptographic algorithms for the use of ESP and AH, specifically with the selection of mandatory-to-implement algorithms. The algorithms identified in this document as "MUST implement" or "SHOULD implement" are not known

to be broken at the current time, and cryptographic research to date leads us to believe that they will likely remain secure into the foreseeable future. However, this is not necessarily forever. Therefore, we expect that revisions of that document will be issued from time to time to reflect the current best practice in this area.
