```

# JSON data model

## **Primitive:**

- null
- false, true
- numbers (decimal float)
- text string (UTF-8)

## **Container:**

- “object” (map, with text string keys only)
- array

# CBOR data model

## Primitive:

- null (+ other “**simple**”)
- false, true
- numbers:
  - **Integer**
  - **Float16, 32, 64**
- text string (UTF-8)
- **byte string**

## Container:

- map (**any key**)
- array
- **Tag** (extension point)

# JSON limitations

- No **binary** data (byte strings)
- Numbers are in **decimal**, some parsing required
- Format requires copying:
  - **Escaping** for strings
  - Base64 for binary
- **No extensibility** (e.g., date format?)
- Interoperability **issues**
  - I-JSON further reduces functionality (RFC 7493)

	Character-based	Concise Binary
Document-Oriented	<b>XML</b>	<b>EXI</b>
Data-Oriented	<b>JSON</b>	<b>???</b>

# BSON and friends

- Lots of “binary JSON” proposals
- Often optimized for data at rest, not protocol use (BSON → MongoDB)
- Most are **more** complex than JSON

# Why a new binary object format?

---

- Different design goals from current formats
  - stated up front in the document
- Extremely **small code size**
  - for work on constrained node networks
- Reasonably **compact data size**
  - but no compression or even bit-fiddling
- Useful to any protocol or application that *likes* the design goals

# Concise Binary Object Representation (CBOR)

“Sea Boar”

	Character-based	Concise Binary
Document-Oriented	<b>XML</b>	<b>EXI</b>
Data-Oriented	<b>JSON</b>	<b>CBOR</b>

# Design goals (1 of 2)

---

1. unambiguously encode most **common data formats** (such as JSON-like data) used in Internet standards
2. **compact implementation** possible for encoder and decoder
3. able to parse **without a schema description.**

# Design goals (2 of 2)

---

4. Serialization reasonably **compact**, but data compactness **secondary** to implementation compactness
5. applicable to both **constrained nodes** and **high-volume applications**
6. support all **JSON** data types, conversion to and from JSON
7. **extensible**, with the extended data being able to be parsed by earlier parsers

# 2013-09-13: CBOR RFC

- “Concise Binary Object Representation”:  
JSON equivalent for constrained nodes
  - start from JSON data model (no schema needed)
  - add binary data, extensibility (“tags”)
  - concise binary encoding (byte-oriented, counting objects)
  - add diagnostic notation
- Done without a WG (with APPSAWG support)

<http://cbor.io>

# CBOR

## RFC 7049 Concise Binary Object Representation

“The Concise Binary Object Representation (CBOR) is a data format whose design goals include the possibility of extremely small code size, fairly small message size, and extensibility without the need for version negotiation.”

### JSON data model

CBOR is based on the wildly successful JSON data model: numbers, strings, arrays, maps (called objects in JSON), and a few values such as false, true, and null.

### No Schema needed

### Embracing binary

Some applications that would like to use JSON need to transport binary data, such as encryption keys, graphic data, or sensor values. In JSON, these data need to be encoded (usually in base64 format), adding complexity and bulk.

### Concise encoding

### Stable format

CBOR is defined in an Internet Standards Document, [RFC 7049](#). The format has been designed to be stable for decades.

### Extensible

To be able grow with its applications and to

# Implementations

- Parsing/generating CBOR easier than interfacing with application
- Minimal implementation: 822 bytes of ARM code
- Different integration models, different languages
- > 25 implementations (after first two years)

The screenshot displays the 'http://cbor.io' website, which lists various implementations of the CBOR (Concise Binary Object Representation) format across different programming languages. The languages are organized into columns: JavaScript, Lua, C#, Java, Python, Perl, C, C++, Go, Ruby, Erlang, Elixir, Rust, Haskell, and D. Each language entry includes a brief description of the implementation, a 'View details' link, and a 'View details' button. For example, the JavaScript section mentions 'A JavaScript implementation is becoming available both for in-browser use and for node.js.' and the Python section mentions 'Install a high-speed implementation via pip: `pip install cbor`'.

<http://cbor.io>

# Batteries included

- RFC 7049 predefines 18 Tags
  - Time, big numbers (bigint, float, decimal), various converter helpers, URI, MIME message
- Easy to register your own CBOR Tags
  - 19 more tags: 6 for COSE; UUIDs, binary MIME, Perl support, language tagged string, compression

# 2015-06-03: COSE WG

- CBOR Object Signing and Encryption:  
**Object Security** for the IoT
- Based on **JOSE**: JSON Web Token, JWS, JWE, ...
  - Data structures for signatures, integrity, encryption...
  - Derived from on OAuth JWT
  - Encoded in JSON, can encrypt/sign other data
- **COSE: use CBOR instead of JSON**
  - Can directly use binary encoding (no base64)
  - Optimized for constrained devices

So, why a WG?

# Take CBOR to STD

## **RFC 6410:**

- independent interoperable implementations ✓
- no errata (oops)
- no unused features
- (if patented: licensing process)

# Take CBOR to STD

- **Do not:** futz around
- Document interoperability
- Make needed improvements in specification quality
  - At least fix the errata :-)
- Are all tags implemented interoperably?

# Next steps

- Create a 7049bis repo on [github.com/cbor-wg](https://github.com/cbor-wg)
  - Leading to draft-ietf-cbor-7049bis shortly
- Start the git-based issues/PR/merge process
- Start a separate feature interoperability list (wiki?)

# CDDL

Henk Birkholz, Christoph Vignano, Carsten Bormann

# FDT in the IETF

- Formal description techniques helped kill OSI
- Takeup of FDT in IETF reluctant
  - A few notable exceptions: e.g. RFC 4997
  - Island of FDT: Management — SMIv2, YANG
- Widely used: ABNF  
(RFC 5234 = STD 68, updated by RFC 7405 (PS))

# ABNF

- BNF: grammars for strings
  - RFC40 (1970): first RFC with BNF
- “Internet” BNF: Augmented BNF (ABNF)
  - RFC 733 (1977): “Ken L. Harrenstien, of SRI International, was responsible for re-coding the BNF into an augmented BNF which compacts the specification and allows increased comprehensibility.”

# ABNF in the IETF

- 752 RFCs and I-Ds reference RFC 5234 (the most recent version of ABNF) [cf. YANG: 160]
- Tool support (e.g., BAP, abnf-gen; antlr support)
- Pretty much standard for text-based protocols that aren't based on XML or JSON

# ABNF is composed of productions

```
addr-spec      = local-part "@" domain
local-part     = dot-atom / quoted-string / obs-local-part
domain         = dot-atom / domain-literal / obs-domain
domain-literal = [CFWS] "[" *([FWS] dtext) [FWS] "]" [CFWS]
dtext          = %d33-90 /           ; Printable US-ASCII
                %d94-126 /          ; characters not including
                obs-dtext           ; "[", "]", or "\"
```

- **Names** for sublanguages
- **Compose** using
  - Concatenation
  - Choice: /
- **Literals** terminate nesting

# From ABNF to CDDL

- Build **trees** of data items, not **strings** of characters
- Add literals for primitive types
- Add constructors for containers (arrays, maps)
- Inspiration: Relax-NG (ISO/IEC 19757-2)

# Rule names are **types**

```
bool = false / true  
label = text / int  
int = uint / nint
```

- Types are **sets** of potential values
- Even literals are (very small) types

```
participants = 1 / 2 / 3  
participants = 1..3  
msgtype = "PUT"  
msgtype = 1
```

# Groups: building containers

- Containers contain sequences (array) or sets (maps) of entries
- Entries are types (array) or key/value type pairs (maps)
- Unify this into **group**:
  - sequenced (ignored within maps)
  - labeled (ignored within arrays)

## How **RFC 7071** would have looked like in CDDL

reputation-object = {	; This is a map (JSON object)
application: text	; text string (vs. binary)
reputons: [* reputon]	; Array of 0- $\infty$ reputons
}	

reputon = {	; Another map (JSON object)
rater: text	
assertion: text	
rated: text	
rating: float16	; OK, float16 is a CBORism
? confidence: float16	; optional...
? normal-rating: float16	
? sample-size: uint	; unsigned integer
? generated: uint	
? expires: uint	
* text => any	; 0- $\infty$ , express extensibility
}	

# Named groups

```
header_map = {  
    Generic_Headers,  
    * label => values  
}  
Generic_Headers = (  
    ? 1 => int / tstr,    ; algorithm identifier  
    ? 2 => [+label],     ; criticality  
    ? 3 => tstr / int,    ; content type  
    ? 4 => bstr,          ; key identifier  
    ? 5 => bstr,          ; IV  
    ? 6 => bstr,          ; Partial IV  
    ? 7 => COSE_Signature / [+COSE_Signature]  
)
```

- Named groups allow re-use of parts of a map/array
- Inclusion instead of inheritance

# GRASP

- Generic Autonomic Signaling Protocol (GRASP)
- For once, try not to invent another TLV format: just use CBOR
- Messages are arrays, with type, id, option:  
    `message /= [MESSAGE_TYPE, session-id, *option]`  
    `MESSAGE_TYPE = 123 ; a defined constant`  
    `session-id = 0..16777215`  
    `; option is one of the options defined below`
- Options are arrays, again:  
    `option /= waiting-time-option`  
    `waiting-time-option = [0_WAITING, waiting-time]`  
    `0_WAITING = 456 ; a defined constant`  
    `waiting-time = 0..4294967295 ; in milliseconds`

# SDOs outside of IETF

- CDDL is being used for specifying both CBOR and JSON in W3C, \_\_\_\_, and \_\_\_\_\_
- Data in flight in a variety of protocols, e.g.
  - Access to specific features in wireless radios
  - Aggregation of metadata, enabling visualization of network topologies

# From draft to RFC

- **Do not:** break it
- Editorial improvements required
- Any additional language features needed?
  - Should stay in the “tree grammar” envelope
- What can we take out?

# computed literals?

- integers relative to an offset  
base = 400  
a = base + 1  
b = base + 2
- string concatenation/interpolation
  - e.g., to build long regexes out of parts

# unpack/inclusion operator?

```
foo-basic = { foo-guts }  
foo-guts = (a: int, b: uint)  
foo-extended = { foo-guts, c: text }
```

- →

```
foo-basic = { a: int, b: uint }  
foo-extended = { <foo-basic, c: text }
```

# representation constraints

- definite vs. indefinite
- Float16, float32, float64
- ...
- (These often can be done on a global level)

# cuts (better error messages)

```
a = ant / cat / elk  
ant = ["ant", ^ uint]  
cat = ["cat", ^ text]  
ant = ["elk", ^ float]
```

```
["ant", 47.11]
```

- tool will not tell you "can't match a",  
but "can't match rest of ant"

# modules

```
;;< module fritz  
;;< export foo, bar  
foo = [baz, ant, cat]  
bar = uint
```

```
;;< module animals  
;;< from fritz import foo
```

- (This is completely unthought-through)
- Proposal: make these a layer on top of CDDL

# interchange as JSON

$a = b / c$

- →

```
[":rule", "a", [":typechoice", "b", "c"]]
```

- Define standard mapping for tools that want to
  - pretty print CDDL
  - reason about CDDL
  - transform CDDL (e.g., for parser generators)

# Avoid the kitchen sink

- This is not a Christmas wish list
- Each feature has a cost
  - specification complexity
  - learning effort
  - implementation effort

# Next steps

- cddl draft already at [github.com/core-wg](https://github.com/core-wg)
- Start the git-based issues/PR/merge process

More tags

# draft-jroatch-cbor-tags-05

- Provide tags for homogeneous arrays represented in byte strings

uint	sint	float
uint8	sint8	binary16
uint16	sint16	binary32
uint32	sint32	binary64
uint64	sint64	binary128

- Inspired by JavaScript
- Both LSB and MSB first
- Reserves 24 tags in 1-byte space
- Provide a tag for other homogeneous arrays
- Provide a tag for multidimensional arrays

# Unchartered Work

# draft-bormann-cbor- time-tag-00

- Nobody knew that time could be so complicated!

# draft-bormann-cbor- time-tag-00

- Limits of CBOR Tag 0/1:
  - Limited resolution
  - Only Posix Time as time scale
  - “Intent” information and other metadata cannot be included
- Start with defining a kitchen sink
  - Then see whether we want to keep all of that
  - Make sure simple things stay simple

# draft-bormann-lpwan-cbor-template

- **variable:** placeholder CBOR data item included in a larger data item (the "CBOR template")
- Relevant for LPWAN SCHC
- But can be used in a general way

# Status of Tags drafts

- OLD: On charter, kitchen sink
- Array: On charter, ready for adoption
- Time: Off charter
- Template: Off charter  
(will likely be done with SCHC anyway)

# Tutorial

# CBOR: Agenda

- What is it, and when might I want it?
- How does it work?
- How do I work with it?

# CBOR vs. “binary JSONs”

- Encoding [1, [2, 3]]: compact | stream

CBOR	82 01 82 02 03	9f 01 82 02 03 ff

# Very quick overview of the format

---

- Initial byte: **major type** (3 bits) and **additional information** (5 bits: immediate value or length information)
- Eight major types:
  - unsigned (0) and negative (1) **integers**
  - **byte** strings (2), **UTF-8** strings (3)
  - **arrays** (4), **maps** (5)
  - optional **tagging** (6) and **simple types** (7) (floating point, Booleans, etc.)

# Additional information

---

- 5 bits
  - 0..23: immediate value
  - 24..27: 1, 2, 4, 8 bytes value follow
  - 28..30: *reserved*
  - 31: indefinite length
    - terminated only by 0xFF in place of data item
- Generates unsigned integer:
  - **Value** for mt 0, 1 (unsigned/neg integers), 7 (“simple”)
  - **Length** (in bytes) for mt 2, 3 (byte/text strings)
  - **Count** (in items) for mt 4, 5 (array, map)
  - **Tag** value for mt 6

# Major types 6 and 7

---

- mt 7:
  - **special** values for  $a_i = 0..24$ 
    - false, true, null, undef
    - IANA registry for more
  - $a_i = 25, 26, 27$ : **IEEE floats**
    - in 16 (“half”), 32 (“single”), and 64 (“double”) bits
- mt 6: semantic **tagging** for things like dates, arbitrary-length bignums, and decimal fractions

# Tags

---

- A Tag contains **one** data item
- 0: RFC 3339 (~ ISO 8601) **text string** date/time
- 1: UNIX time (**number** relative to 1970-01-01)
- 2/3: bignum (**byte string** encodes unsigned)
- 4: [**exp, mant**] (decimal fraction)
- 5: [**exp, mant**] (binary fraction, “bigfloat”)
- 21..23: expected conversion of **byte string**
- 24: nested CBOR data item in **byte string**
- 32...: URI, base64[url], regexp, mime (**text strings**)

# New Tags

---

- Anyone can register a tag (IANA)
  - 0..23: Standards action
  - 24..255: Specification required
  - 256..18446744073709551615: FCFS
- 25/256: stringref for simple compression
- 28/29: value sharing (beyond trees)
- 26/27: constructed object (Perl/generic)
- 22098: Perl reference (“indirection”)

# Examples

---

- Lots of examples in RFC (making use of JSON–like “**diagnostic notation**”)
- 0 → 0x00, 1 → 0x01, 23 → 0x17, 24 → 0x1818
- 100 → 0x1864, 1000 → 0x1903e8, 1000000 → 0x1a000f4240
- 18446744073709551615 → 0x1bffffffffffffff, 18446744073709551616 → 0xc249010000000000000000
- −1 → 0x20, −10 → 0x29, −100 → 0x3863, −1000 → 0x3903e7
- 1.0 → 0xf93c00, 1.1 → 0xfb3ff1999999999999a, 1.5 → 0xf93e00
- Infinity → 0xf97c00, NaN → 0xf97e00, −Infinity → 0xf9fc00
- false → 0xf4, true → 0xf5, null → 0xf6
- h" → 0x40, h'01020304' → 0x4401020304
- "" → 0x60, "a" → 0x6161, "IETF" → 0x6449455446
- [] → 0x80, [1, 2, 3] → 0x83010203, [1, [2, 3], [4, 5]] → 0x8301820203820405
- {} → 0xa0, {1: 2, 3: 4} → 0xa201020304, {"a": 1, "b": [2, 3]} → 0xa26161016162820203

# CBOR: Agenda

- What is it, and when might I want it?
- How does it work?
- How do I work with it?

# <http://cbor.me>: CBOR playground

- Convert back and forth between **diagnostic notation** (~JSON) and binary encoding

## CBOR

Diagnostic 

 5 Bytes

[1, [2, 3]]

82	# array(2)
01	# unsigned(1)
82	# array(2)
02	# unsigned(2)
03	# unsigned(3)

# Offline tools (gem install)

- cbor-diag:  
offline (command line) version of cbor.me
- cddl: generate examples from CDDL, verify instances against CDDL, extract code definitions from CDDL

# Implementations

- Parsing/generating CBOR easier than interfacing with application
- Minimal implementation: 822 bytes of ARM code
- Different integration models, different languages
- > 25 implementations (after first two years)

The screenshot displays the 'Implementations' page of the cbor.io website, organized into a grid of language categories. Each category includes a brief description of the implementation and a 'View details' link.

- JavaScript**: JavaScript implementations are becoming available both for in-browser use and for node.js.
- Browser**: A CBOR object can be installed via `browser: install cbor` and used as an AMD module or global object in the browser e.g. in combination with Websockets...
- node.js**: ... and the server side for that might be written using node.js. Install via: `npm install cbor`
- PHP**: API: `\CBOR\CBOR\Encoder::encode($target)` and `\CBOR\CBOR\Encoder::decode($encoded)`
- Go**: An early Go implementation that feels like the JSON library.
- Rust**: A Rust implementation is available that works with Cargo and is on [crates.io](#).
- JavaScript** (continued): ... and the server side for that might be written using node.js. Install via: `npm install cbor`
- PHP** (continued): API: `\CBOR\CBOR\Encoder::encode($target)` and `\CBOR\CBOR\Encoder::decode($encoded)`
- Go** (continued): An early Go implementation that feels like the JSON library.
- Rust** (continued): A Rust implementation is available that works with Cargo and is on [crates.io](#).
- JavaScript** (continued): ... and the server side for that might be written using node.js. Install via: `npm install cbor`
- PHP** (continued): API: `\CBOR\CBOR\Encoder::encode($target)` and `\CBOR\CBOR\Encoder::decode($encoded)`
- Go** (continued): An early Go implementation that feels like the JSON library.
- Rust** (continued): A Rust implementation is available that works with Cargo and is on [crates.io](#).

Other languages shown include Lua, Python, Perl, Ruby, Erlang, Elixir, Haskell, C#, Java, C, C++, and D.
